THE DAIRY POSITION IN BRIEF

Butter production was maintained at a high level in August. The creamery butter output increased $6\frac{1}{2}$ per cent and dairy butter 5 per cent as compared with the same month a year ago. The August make of creamery butter amounted to $36\frac{1}{2}$ million pounds, while dairy butter was estimated at approximately 4 million pounds. Whey butter, on the other hand, fell from 336 thousand pounds in August, 1946 to 256 thousand pounds in August, 1947.

Total butter supply in August was slightly more than 100 million pounds, approximately 3 million pounds more than that of August, 1946. This includes stock holdings of 59 million pounds on August 1, and total production of 41 million pounds.

Domestic disappearance of creamery butter in August amounted to $28\frac{1}{2}$ million pounds as compared with $23\frac{3}{4}$ million pounds; and total butter was $32\frac{3}{4}$ million pounds in comparison with $27\frac{1}{2}$ million pounds in August, 1946.

While the butter supply position has been strengthened by increased production, the supply is not keeping pace with the demand. Total butter supply in August increased 3 per cent, while domestic disappearance exceeded that of the same month last year by over 19 per cent. This was reflected in the stock position at September 1, the 67 million pounds in store and transit representing a decrease of 3 per cent from the same date of the previous year.

Wholesale butter prices at Montreal quoted by the Canadian Commodity Exchange averaged $55\frac{1}{4}$ cents per pound in August as against 40 cents in the same month of 1946. Cheese prices averaged 26 cents. In August, 1946, the average was 23 cents.

The estimated total milk production of Canada amounted to 2,041 million pounds in July, one-half of one per cent more than that produced in the same month of 1946. In the seven-month period January to July, 10,162 million pounds were produced representing a decline of 69 million pounds or three-quarters of one per cent.

Fluid sales including both milk and cream approximated 355 million pounds, 3 per cent below those of July, 1946. Sales of fluid milk declined 8 per cent, while fluid cream sales increased 25 per cent. Deliveries to dairy factories were almost equal to those of July, 1946.

Sales income from dairying in the month of June registered a gain of approximately $2\frac{1}{2}$ million dollars in comparison with that of June, 1946. The total income of approximately 39 million dollars averaged \$2.16 per hundred pounds of milk as against \$2.01 per hundred in the same month of the previous year.

The numbers of milch cows on farms in July were 2 per cent less than those recorded twelve months ago. While labour is difficult to procure for dairy farms, the situation appears to be improving, and is less acute than in 1946.

August was an exceptionally warm month in eastern Canada with high temperatures and light rainfall. In western Canada, it was inclined to be cool. There was more than the usual amount of rain in the Prairie Provinces, but precipitation was slightly less than normal in British Columbia.

Pastures showed the effects of inadequate moisture supplies in the lower St. Lawrence and Prince Edward Island, while in sections of Nova Scotia drought conditions prevailed. Timely rains arrested the midsummer drought in the Prairie Provinces, but in some sections the precipitation was too late to affect a recovery on grazing lands. The hay crop was about 9 per cent greater than in 1946, but the coarse grains harvest (barley and oats), declined approximately 20 per cent. There is unlikely to be any significant change from last year in the quantity of milk produced during the autumn months.

1/ Data for August, 1947 are preliminary; revisions for July appear on Table 7.
2/ Includes Whey Butter amounting to 336,400 pounds in August, 1946 and 255,642 pounds in August, 1947. 3/ Note the base index in each column is shown as 100.

THE DAIRY SITUATION IN CANADA

The Butter Position: Total butter supply for export and domestic use amounted to slightly more than 100 million pounds in the month of August, or approximately 3 million pounds more than that of August, 1946. (x) There has been a high level of production during the past three months. In August, the creamery butter output of $36\frac{1}{2}$ million pounds represented an increase of $6\frac{1}{2}$ per cent over the same month last year; and the January-August production of $204\frac{1}{2}$ million pounds was $2\frac{1}{2}$ per cent greater than that produced during the first eight months of the preceding year. Dairy butter also increased, the estimated output of approximately 4 million pounds in the month of August was 5 per cent greater than that of the same month a year ago. Due to the continuous decline in cheese production, less whey butter was made, the output falling from 336 thousand pounds in August, 1946 to 256 thousand pounds in August, 1947.

While the figures given above would indicate a very satisfactory situation as far as butter supply is concerned, it must be remembered that the demand for butter is moving forward at a much faster pace than production. On the first of August, the stocks of creamery butter were approximately $\frac{1}{2}$ million pounds greater than those reported at the same date a year ago. On September 1, the 67 million pounds held in storage and transit represented a reduction of $1\frac{1}{2}$ million pounds as compared with September 1, 1946. Domestic disappearance of creamery butter during August was $28\frac{1}{2}$ million pounds as against $23\frac{1}{4}$ million pounds a year ago. Similarly, the domestic disappearance of total butter moved up to $32\frac{3}{4}$ million pounds as against $27\frac{1}{2}$ million pounds in August, 1946.

The foregoing facts are significant. In comparison with the same month of the previous year, the production of total butter in the month of August (creamery, dairy and whey butter), increased 6.2 per cent, and total butter supplies, calculated by adding stocks and production, moved up 3.0 per cent. On the other hand, total butter stocks at September 1 declined 2.3 per cent and the domestic disappearance was 19.2 per cent greater than that shown in August, 1946. This tendency for disappearance to move up faster than the supply was much more pronounced in August than in the previous month and shows little indication of consumer resistance to higher prices.

Supply of Other Factory Products: Cheddar cheese production continues to decline. The August output of $18\frac{1}{2}$ million pounds was down approximately $2\frac{3}{4}$ million pounds or 13 per cent as compared with the same month in 1946. Cumulative production for the January-August period was approximately 86 million pounds, a decrease of over $18\frac{1}{2}$ million pounds or nearly 18 per cent less than that produced in the same period a year ago. This reduced output may be due in part to a slight reduction in the quantity of milk produced, but more particularly to a diversion of milk into the creamery butter and the fluid milk trade.

Supplies of concentrated milk products continued to advance. In the month of August, whole milk products increased over 5 per cent, while milk by-products were 30 per cent greater than those of the same month in the previous year. The combined production of $35\frac{1}{2}$ million pounds represents more than a 10 per cent gain over a year ago. All products contributed to this increase except condensed whole milk, whole milk powder and condensed skim milk.

(x) The total supply includes production during the month, plus stocks carried over from the previous month. No butter has been imported since March.

1/ Includes other cheese produced in Quebec, 1936 to 1939. 2/ Farm-made cheese is included in data shown in this column. - Not available. = Imports not available (see Trade Report No. 101 for data).

Since the removal of restrictions on the manufacture of ice cream, there has been a steady advance in the quantity produced. The most significant gain was recorded in the month of August when $3\frac{3}{4}$ million gallons were manufactured as compared with a little more than 2 million gallons in the same month of 1946. This represents an increase of over 79 per cent. Ice cream production for the eight months ended August reached approximately $17\frac{1}{4}$ million gallons, 41 per cent more than that produced in the first eight months of 1946.

Milk Production: The estimate of total milk production for July is 2,040,929,000 pounds or one-half of one per cent more than that produced in the corresponding month of 1946. For the seven-month period, January to July, the output amounted to 10,162,000,000 pounds or 69 million pounds less than that produced in the first seven months of 1946. The July increase was due entirely to additional quantities produced in Quebec and Ontario. Reductions occurred in all other provinces, British Columbia and Prince Edward Island both registering declines of $5\frac{1}{2}$ per cent. In Nova Scotia, the output was within one per cent of that of a year ago.

Fluid Sales: The quantity of milk, and cream in terms of milk, sold for fluid consumption in July was 355,197,000 pounds or approximately 3 per cent less than that of July, 1946. However, there was a sharp difference between milk sales and cream sales. The 288 million pounds used in the form of milk represented a reduction of 8 per cent while the 67 million pounds used for fluid cream was 24.8 per cent more than that of July, 1946. All provinces showed reductions in the sale of fluid milk. Gains in the sale of fluid cream were recorded in all provinces with the exception of Saskatchewan and British Columbia. There was practically no change from last year in the percentage relationship between fluid sales and the total milk supply.

Milk Used for Other Purposes: The delivery of milk to dairy factories in July was practically equal to that of the same month last year. Small increases occurred in Quebec and British Columbia, while quite a substantial advance was registered in Ontario. Elsewhere, less milk was used for the production of factory products. A considerable gain occurred in the manufacture of dairy butter while less milk was fed to live stock. The percentage of milk used for different purposes in July, 1947, varied only slightly from last year. Small gains were recorded in the proportion used for factory products and farm-made products. In July, 1947, 67.5 per cent was used in dairy factory production and 5.3 per cent in farm-made products.

Sales Income: The cash farm income from the sale of dairy products in June was \$38,981,000. This represents an increase of approximately $2\frac{1}{2}$ million dollars or $6\frac{1}{2}$ per cent over June, 1946. The average sale price was \$2.16 per hundred pounds of milk as compared with \$2.01 per hundred pounds in June, 1946. The income from fluid milk sales averaged \$3.34 as against \$2.81 per hundred, and income from fluid cream sales showed an average of \$2.01 in June, 1947, as compared with \$1.73 in June, 1946. Milk used in concentration moved up to \$2.25 per hundred pounds as compared with \$2.04 in the same month a year ago, while butter-fat increased from 49.3 cents to 51.8 cents. Dairy butter also reacted to the higher price level of the creamery product, averaging $47\frac{1}{2}$ cents as compared with 39.8 cents in June, 1946.

Production Conditions on Farms: The month of August was extremely warm and comparatively dry in most sections of the Eastern Provinces. Dry weather injured pastures to a limited extent in the eastern and southern counties of Ontario, and in the lower St. Lawrence area. In Nova Scotia a more pronounced drought condition prevailed, and the growth of grass on pastures became seriously depleted during the last two weeks of August. This applies to a lesser extent to Prince Edward Island. In New Brunswick, forage conditions were better than those of a year ago. In western Canada, the weather was cool and frequent rains revived pastures that had suffered

from the intense midsummer heat. In some areas, however, the growth was too far gone to affect a recovery. Observers are of the opinion that crop reverses experienced by farmers in northern parts of Saskatchewan and Alberta will tend to increase interest in the production of dairy products. The satisfactory progress in harvesting grain crops in the Prairie Provinces should release fields for the use of dairy herds somewhat earlier than last year, and produce a favourable effect on dairy production during the autumn period.

The second estimate on the production of field crops would indicate a considerable fall-off in the supplies of oats and barley. Converted to common measurements, the total production would represent the equivalent of approximately $10\frac{1}{2}$ million tons or about 20 per cent less than that produced a year ago. These disappointing results were partially offset, however, by a good hay crop. Combining hay and alfalfa, a total of $18\frac{3}{4}$ million tons is shown in the estimates for 1947, representing a gain of over 9 per cent. The production of fodder corn was less than last year, but this reduction may be offset by a good root crop in the Eastern Provinces. The average condition of pastures at the end of August (see Table 8), was 86 per cent of normal for the whole of Canada as compared with 75 per cent in August, 1946. Because of drought conditions in Nova Scotia, Saskatchewan and Alberta, the conditions were below the average of a year ago.

The number of cows being milked in July was 2 per cent less than for July, 1946. All provinces contributed to this reduction except Prince Edward Island and Quebec where slight increases were reported. There was very little change in freshenings.

The supply of farm labour is still deficient; although Observers report that the situation is improving and that the demand for farm workers is now within 10 per cent of current requirements. The greatest shortage appears to prevail in areas where farmers are competing with the lumbering and logging industries.

While it is difficult to make any forecast on the production of milk in future months, present indications would point to a comparatively small decline during September and October. The shortage of feed is likely to have an adverse effect on milk supplies in some areas after dairy herds are deprived of the open fields.

REVIEW OF DAIRY PRODUCTION CONDITIONS BY PROVINCES

Prince Edward Island: The July milk production estimate of approximately 22 million pounds was almost 6 per cent less than that produced a year ago. Fluid milk sales showed a corresponding decline while dairy butter moved up 6 per cent from the same month a year ago. Dairy Correspondents reported an increase of 3 per cent in cow numbers, but this was offset by a corresponding decline in the percentage of cows milked. Freshenings advanced in July and more recent reports from Dairy Farm Observers indicate that a tendency to increase the size of dairy herds is beginning to appear. Extremely dry weather prevailed during the month of August. Moisture reserves were noticeably deficient by the middle of the month, and although pastures showed the effects of the midsummer drought, the average condition of 64 per cent of normal was somewhat better than last year.

Nova Scotia: Milk production during the month of July amounted to 48,700,000 pounds, only 1 per cent less than that of July, 1946. The total sold for milk and cream was reduced by 5 per cent, while the dairy butter made advanced 10 per cent. The holdings of milch cows suffered a further decline, being 4 per cent less than those reported by Dairy Correspondents a year ago. The percentage milking was well

Note - Supply data which appear in the first and third columns includes stocks at the beginning of the month, plus production and imports during the month. (1) Less than 500 lbs. (2) Not available on date of publication. (3) Stocks in the hands of wholesalers not included in data for September 1, 1947.

maintained and freshenings increased as compared with the same month last year. Pastures suffered a severe set-back as a result of very dry weather during the month of August. In some areas, the growth was almost depleted, suffering deficiencies of 25 to 30 per cent. In the province as a whole, an average condition of 64 was revealed, 5 points less than August, 1946. There was a considerable reduction in the coarse grains harvest, but the hay crop now estimated at 767 thousand tons will be considerably greater than that produced in the previous year.

New Brunswick: It will be seen from Table 9 that the milk production estimate for the month of July represented a decline of $4\frac{1}{2}$ per cent from the same month last year. Considerably more milk was used for dairy butter, the monthly make having advanced 9 per cent over July, 1946. Fluid sales declined 5 per cent, a large proportion of which was sold in the form of cream. Both fluid sales and dairy butter absorbed a greater percentage of the total supply than in the same month last year. Cow numbers suffered a further reduction, being nearly 7 per cent less than those reported a year ago. Freshenings increased considerably in July while the percentage of cows being milked fell to a slightly lower level. With abundant reserves of moisture and frequent showers, the condition of pastures was somewhat better than in other parts of the Maritime Provinces. At the end of the month, the pasture condition was 85 as against 64 in August, 1946. The latest crop estimate showed a reduction of approximately 600 thousand bushels in the production of oats and a decline of 49 thousand in the production of barley. The hay crop, estimated at 829 thousand tons, will represent an increase of 118 thousand tons over that of 1946.

Quebec: The milk production estimate of 626 million pounds in the month of July represented an increase of $1\frac{1}{2}$ per cent over the same month last year. This may be attributed to the excellent pasture growth reported in the previous issue of this review. It is also of interest to observe that the fluid milk sales (including milk and cream on a milk basis), increased 1 per cent and the production of dairy butter was 8 per cent greater than that of July, 1946. Farmers appear to be holding about the same number of cows as they did last year, and the percentage of cows milked stands at the 1946 level. Freshenings were considerably reduced in July and this may have an appreciable effect on the holdings of milch cows in subsequent months. July reports show a substantial increase in the milk production per cow. Pasture growth was fairly well maintained until the middle of August when the abnormally dry weather showed its effects. Counties in the lower St. Lawrence seemed to have suffered to the greatest extent. The abundant moisture reserves was a saving factor so that the average pasture condition of 86 compares with 79 in August, 1946. The latest crop estimate indicates that the production of oats will be down 7 million bushels from last year. On the other hand, the hay crop was approximately $1\frac{1}{2}$ million tons more than last year. While farmers may be short of home-grown grains, there should be ample roughage for feeding dairy cattle during the winter months.

Ontario: The quantity of milk produced on farms in the month of July was $4\frac{1}{2}$ per cent greater than that of a year ago. The excellent forage conditions during the month was probably responsible for this favourable development. It is particularly significant that this increase occurred in face of a reduction in cow numbers. This was due to the increase in milk production per cow which rose from 22.6 to 24 pounds per day. Factory deliveries moved up nearly 8 per cent, while the dairy butter make increased 11 per cent. Fluid sales suffered the consequences of this diversion to dairy factories by a 5 per cent decline as compared with July, 1946. Hot weather during the month of August had a very serious effect on the farm output. The drought which frequently invades the eastern and southern counties during July came about two or three weeks later than usual and consequently, the damage to pastures was much less severe. In the province as a whole, the average condition

(1) Condensed skimmilk is not separately listed in import returns. Condensed milk designated as such shown in trade reports consists principally of condensed whole milk products.

(2) Not available at date of publication.

of pastures was 93 per cent of normal in comparison with 72 per cent a year ago. There was a considerable reduction in the coarse grains harvest. The oat crop suffered a decline of 30 million bushels, while barley production fell 10 million bushels as compared with 1946. Feed shortages may effect dairy production during the late fall and winter months. The hay crop, estimated at approximately 1 million tons above that of a year ago, may be a saving factor.

Manitoba: Milk production in this province suffered a slight recession, falling $2\frac{1}{2}$ per cent below that of July, 1946. This was probably due to deficient forage supplies resulting from the dry hot weather which prevailed during the latter part of the month. This was reflected in the deliveries to dairy factories which fell $3\frac{1}{2}$ per cent. The utilization figures shown in Table 8 reveal a 3 per cent decline in fluid sales, yet, the quantities used for dairy butter and farm home consumption increased 4 per cent and 2 per cent, respectively. Cow numbers reported by Dairy Correspondents registered a decline of approximately 3 per cent in the month of July as compared with the same month a year ago. This reduction corresponds closely with the decline in milk production, but represented a more favourable situation than that reported a month ago when cow numbers were nearly 6 per cent below those of June, 1946. August was unusually cool, and weather records at Morden showed a total precipitation of 7.24 inches of rain against 1.80 inches in the same month of the preceding year. Hence, pasture growth was exceedingly satisfactory. The average rating of 100 in the month of August was 16 points better than that reported in August, 1946.

Saskatchewan: There was a decline of 4 per cent in the estimated production of milk in the month of July as compared with that of July, 1946. This decline was somewhat greater than in June. The hot dry weather in July had a pronounced effect on the deliveries of milk to dairy factories, which fell $5\frac{1}{2}$ per cent below those of the same month in 1946. Less milk was used for fluid purposes. Despite the advance in cream consumption, the sales of milk and cream combined were 2 per cent less than in July, 1946. There was also a 3 per cent reduction in the quantities used in farm homes. There appears to be a tendency on the part of farmers to restrict their purchases of creamery butter, but without any material increase in the quantities produced in farm homes, which was only $1\frac{1}{2}$ per cent more than that produced in July, 1946. The numbers of milch cows on farms dropped approximately 4 per cent in July, and the average production of milk per cow reflected the inadequate forage situation reported during the last half of July. While there was a good deal of warm weather during the first part of August, timely rains which began about August 15, did much to revive pastures that had suffered from the midsummer drought. At Scott, 2.87 inches of rain was recorded as compared with 4.25 inches in 1946; and 253 hours of sunshine in August, 1947, may be compared with 278 hours in the same month of 1946. The average condition of pastures in August was 78 per cent of normal as against 81 per cent a year ago. The most recent estimates place the production of oats in Saskatchewan at 84 million bushels, a reduction of 28 per cent; while the barley crop is estimated at approximately 48 million, a decline of 4 per cent as compared with 1946.

Alberta: The quantity of milk produced in the month of July amounted to 200,702,000 pounds, a decline of approximately 3 per cent from the same month last year. Deliveries to dairy factories showed a slightly greater reduction while fluid sales fell 3 per cent below those of July, 1946. A considerable quantity of dairy butter is being made, the July returns showing an increase of 6 per cent. The reduction in milk supplies was due principally to a fall-off in the production of milk per cow. However, it is encouraging to observe that cow numbers were only 1 per cent below those of July, 1946. This represented a considerable improvement from the previous month, although it is well to bear in mind that the cows reported on

farms cannot always be regarded as potential milk producers. There was quite a decline in freshenings, reversing the favourable development that had been reported a month ago. At Olds, the average temperature of 55.8 degrees was the lowest in fifteen years. There was also a good deal of rain, records at the same station showing 4.69 inches as compared with 2.57 inches in 1946 and a thirty-year average of 2.64 inches. As compared with last year, the condition of pastures was about 5 per cent better in northern Alberta, but 10 per cent poorer in southern areas. For the province as a whole, the pasture rating was 87 as against 93 in the same month of the previous year. The growth of grass has recently improved, but farmers will have smaller supplies of feed grains. While the barley crop moved up 6 per cent, the oat crop, estimated at 78 million represents a decline of 25 per cent.

British Columbia: The estimated milk production of 57,387,000 pounds for the month of July as shown in Table 9 indicated a decline of 5½ per cent from the same month last year. Factory deliveries were not affected to the same extent, but the quantities used for fluid milk and farm home consumption fell 4 per cent and 6 per cent, respectively, as compared with July, 1946. Slightly more dairy butter is being made probably due to the tendency on the part of farmers to make their own rather than to purchase butter at high prices. The fall-off in farm milk supplies may be attributed largely to a reduction in the numbers of cows on farms and to a considerable decline in freshenings during the month of June. The month of August was comparatively dry, and pastures on Vancouver Island suffered particularly from the midsummer drought. In the Fraser River Valley, cool, dry weather prevailed with only 70 inches of rain at Agassiz as compared with the fifty-four-year average of 2.1 inches. The average temperature of 62.6 degrees was also below normal. Pasture growth was well maintained throughout the lower mainland, and regardless of moisture deficiencies in some sections, the average condition in the province as a whole was within 10 per cent of normal, which was exactly the same as that of August, 1946.
