THE DAIRY POSITION IN BRIEF

Butter production in September, 1947, was the highest for that month since 1942. The creamery butter make in September exceeded that of the same month of the previous year by 28 per cent. Dairy butter increased 5 per cent. Total butter production was $7\frac{1}{2}$ million pounds greater than that produced in the same month last year. The total butter supply was approximately 106 million pounds, an advance of 6 per cent over September, 1946.

Stocks of butter at October 1 amounted to 74 million pounds, a gain of $2\frac{3}{4}$ million pounds over the same date in 1946.

The domestic disappearance of total butter amounted to 32 million pounds, 13 per cent greater than that of September, 1946; and for the nine-month period ended September, it reached a total of 257 million pounds or 11 per cent above the January-September disappearance of 1946. This represented a gain of 2 pounds per capita. The favourable production and supply position must be discounted, therefore, by the substantial increase in the rate of domestic disappearance.

Wholesale butter prices at Montreal quoted by the Canadian Commodity Exchange averaged 59 1/8 cents per pound in September as against 40 cents in the same month of 1946. Cheese prices averaged 26 cents as against 23 cents in the same month of the previous year.

The total milk production of Canada in August amounted to 1,806 million pounds, nearly $2\frac{1}{4}$ per cent more than that produced in the same month of 1946.

Fluid sales fell to $335\frac{1}{2}$ million pounds in August, representing a reduction of 3 per cent in comparison with the same month a year ago. Milk sales dropped $8\frac{1}{2}$ per cent while cream sales advanced nearly 27 per cent.

The total quantity of milk used in manufacture in the month of August was $4\frac{1}{2}$ per cent greater than that used in the same month of 1946.

Sales income from dairying in the month of July reached a total of \$38,367,000, an advance of 32 million dollars as compared with a year ago. This represented an average of \$2.18 per hundred pounds of milk as compared with \$1.99 in July, 1946.

The numbers of milch cows on farms declined 2 per cent in August as compared with the same month last year.

With the removal of ceilings, mill feeds have increased by as much as \$10.00 a ton and large increases in the prices of concentrates also occured during the latter half of September.

Pasture conditions were quite satisfactory in September as the result of rainfall during the latter part of the month. The second growth on fallow lands and barvest fields provided excellent forage for dairy stock. The milk supply will probably be maintained somewhat above the 1946 level during the early fall months.

THE DAIRY SITUATION IN CANADA

Butter

In September the total butter supply in Canada was 106 million pounds. This was 6 million pounds above last month and also 6 million pounds above the supply shown in the same month of the previous year. Compared with a year ago, the September production of creamery butter increased 28 per cent while production of dairy butter moved up 5 per cent. Total butter production was $7\frac{1}{2}$ million pounds greater than that of September, 1946. Total production of butter in the nine-month period, January to September, was 284 million pounds. This was an increase of 14 million pounds or 5 per cent more than that produced in the same period of 1946.

Storage stocks of butter on October 1 amounted to 74 million pounds, an increase of $2\frac{3}{4}$ million pounds over the same date in 1946. September 1 stocks, on the other hand, were slightly below those of September, 1946. Stocks usually reach a seasonal high-point on October 1, so that these figures have more than the usual significance. Stocks at October 1, 1947 were the highest since 1943.

The quantity held, however, must be considered in relation to consumption requirements. Domestic disappearance of total butter during September of this year amounted to 32 million pounds, about 13 per cent greater than for the same month in 1946. For the nine months ended September, it was 257 million pounds against 252 million pounds compared with the same period last year, a percentage increase of 11 per cent. The per capita disappearance this year to date is almost 2 pounds higher than last year.

The butter situation may be summed up as follows: Total production in September, 1947, was 24 per cent greater than September, 1946, and the total supply of butter was 6 per cent in excess of that available in the same month a year ago. Likewise, in the January-September period, production increased 5 per cent and the total supply advanced 9 per cent. This favourable situation, however, must be partially discounted by the substantial increase in the rate of domestic disappearance.

Supply of Other Factory Products: The production of chedder cheese in the month of September was slightly less than 15 million pounds, a decline of 14 per cent as compared with September, 1946. The total produced in the three-quarter period of 1947, was slightly over 101 million pounds, representing a decline of 17 per cent from the same period of the previous year. It is obvious that the diversion of milk to the creamery butter channel as a result of higher prices and the increased demand on domestic markets, is having an adverse effect on the output of cheese.

The quantities of concentrated milk products manufactured during September indicate that the trend is still moving in an upward direction. Compared with the same month of the previous year, whole milk products increased approximately 21 per cent and milk by-products advanced 43½ per cent. Combining all products into one group, the total production of 34,299,000 pounds was $25\frac{1}{2}$ per cent greater than that produced in September, 1946. All products contributed to this increase except whole milk powder which showed a decrease of 11 per cent.

The production of 2,541,000 gallons of ice cream was the highest production since 1939; and the increase of almost 100 per cent over the previous September was the most substantial gain since the removal of sales restrictions on this product. So far this year, 19,831,000 gallons have been manufactured, which represents an increase of approximately 47 per cent over the January-September production in 1946.

⁻ Not available

⁼ Imports not available (see Trade Report No. 101 for data).

Milk Production: Milk production is being well maintained despite the decrease in cow numbers and unfavourable pasture conditions in some parts of the country. The estimated production of 1,806,000,000 pounds in the month of August was nearly $2\frac{1}{4}$ per cent more than that produced in the corresponding month of 1946. It is also encouraging to observe that all of the Eastern Provinces registered substantial gains. Slight advances were also recorded in Manitoba and British Columbia.

Fluid Sales: The quantity of milk and cream represented in fluid sales showed a reduction of approximately 3 per cent in August as compared with the same month a year ago. This decline was practically the same as that recorded a month ago. The August estimate shows that 269 million pounds were sold as milk and 67 million pounds in the form of fluid cream expressed as milk. In comparison with the same month of the preceding year, milk sales declined 8.5 per cent while cream sales increased 26.8 per cent. Milk sales declined in all provinces with the greatest reductions in Quebec and Ontario. In these provinces the reductions were 11 per cent and $9\frac{1}{2}$ per cent respectively. A substantial decline in cream sales was reported in Prince Edward Island, while slight reductions were indicated in Saskatchewan and British Columbia.

Milk Used for Other Purposes: The demand for butter and the consequent increase in the prices paid for creamery butter-fat (see summary on first page of this report), has had considerable effect on the quantities used in creamery production. Thus, in spite of a decline in the deliveries of milk to cheese factories, the total used in manufacture for the month of August was $4\frac{1}{2}$ per cent greater than that in the same month of the previous year, and nearly 66 per cent of the total milk production of Canada was used for this purpose as compared with a little more than 64 per cent a year ago. Likewise, the demand for dairy butter has made it necessary for farmers to retain larger quantities of milk on the farm, the quantities so used being $4\frac{1}{4}$ per cent above those of August, 1946. In Table figures are presented which show the percentages of milk used for various purposes. The totals for Canada show that greater proportions of the Dominion's milk supply were used for creamery butter, dairy butter, concentrated milk products and ice cream, while the relative quantities represented in fluid sales, factory cheese and for other purposes were below those of August, 1946.

Sales Income: Farm income from dairying in July moved up to \$38,367,000. This represented an advance of about $3\frac{1}{2}$ million dollars with an average of \$2.18 per hundred pounds of milk as compared with \$1.99 in 1946. Higher prices for cheese milk, fluid milk and milk for concentration contributed to this advance, while an increase of 3 cents per pound in the price of creamery butter-fat and 9 cents per pound in the price of dairy butter enhanced the farm income to a very considerable degree.

Production Conditions on Farms: Exceptionally warm weather prevailed in the Eastern Provinces during the first half of September, while comparatively cool weather prevailed during the latter part of the month. On the whole there was less sunshine than in September, 1946, while temperatures were practically on a par with those of a year ago. In western Canada, frequent rains occured and the weather was inclined to be cloudy and rather cool in most sections of the West.

While rainy weather postponed threshing operations and the clearing of harvest fields for dairy herds, the increased precipitation produced an abundant supply of second-growth-forage on fallow lands and other fields available for pasture purposes. Pastures that partially dried up during the summer months were also revived and are now in a more verdant condition at this season than for many years. According to crop correspondents the average condition of pastures in September was 88 per cent of the long-time average as compared with 75 per cent in September, 1946. This improvement in the condition of pastures was very definitely indicated in the provinces of New Brunswick, Quebc, Ontario, Manitoba and Saskatchewan. During the autumn period when dairy herds have

access to open fields, milk production promises to show an increase over the previous year. There is an element of doubt, however, in regard to the effect of decreased grain yields on the production of milk in subsequent months. Feed grain prices will also play an important part in the future position. With the removal of ceilings, mill feeds have increased by as much as \$10.00 a ton. Large increases in prices have also occured in protein feeds, beet pulp and brewers grains. Many observers are of the opinion that this will tend to reduce the holdings of cattle kept for milking purposes, particularly in view of the continued high cost of labour.

The numbers of cows kept for milking purposes as reported by dairy correspondents in the month of August showed a 2 per cent decline compared with those on farms in the same month a year ago. This situation is comparable to that reported in previous months. In some districts farmers are introducing a greater number of young heifers into dairy herds, although it is doubtful if this will represent an increase in numbers when disposal of older stock is taken into account

While milk production cannot be forecast over a long period of time, it is now evident that supplies will be maintained somewhat above the 1946 level during the early fall months.

REVIEW OF DAIRY PRODUCTION CONDITIONS BY PROVINCES

Prince Edward Island: Milk production in August was 5 per cent greater than that recorded in the same month last year. Creameries benefited from the increased supply and also from the diversion of milk from the fluid trade. Although there was a reduction of $l_2^{\frac{1}{2}}$ per cent in the holdings of milch cows, those cows that were actually milking showed a higher average yield per cow than was the case a year ago.

The weather in September was very favourable for farm work, but since pastures were quite poor (showing an average of 53 for the province as compared with 63 a year ago), it was necessary for farmers to do a considerable amount of supplementary feeding in order to maintain the milk flow.

Nova Scotia: The estimated production of milk for the month of August advanced 5 per cent in comparison with the same month of 1946 (see Table). This was reflected in the creamery butter make and in the total used by dairy factories. The latter represented an increase of 13 per cent. The dairy butter make also increased 6 per cent as compared with the September make in 1946. With a similar decline in fluid sales it is now evident that more and more milk is being diverted into manufacturing channels. A 2 per cent decline in the numbers of milch cows reported was offset by a greater percentage actually milked.

The weather was dry during September and occasional rains failed to revive pasture growth. With a few exceptions, there will be sufficient hay to meet farmers needs, but the yield of coarse grains was disappointing and will probably result in a short supply for the winter months.

New Brunswick: A 5 per cent advance in milk production was indicated in the over-all estimate for August as compared with the same month of the previous year. This increase, coupled with a decrease in fluid sales provided more milk for the production of butter. The creamery make increased nearly 8 per cent while dairy butter production moved up 4 per cent. A reduction of over 5 per cent in the numbers of milch cows was offset by the high percentage of cows being milked (see Table), and a greater yield of milk per cow.

Note - Supply data which appear in the first and third columns includes stocks at the beginning of the month, plus production and imports during the month. (1) Less than 500 lbs. (2) Not available on date of publication. (3) Stocks in the hands of wholesalers not included in data for October 1, 1947.

September was bright and sunny at the beginning, while cool weather with occasional frosts was reported in the latter part of the month. The precipitation was about normal with slightly lower temperatures than in September, 1946.

Quebec: The farm output of milk in this province was $3\frac{1}{2}$ per cent greater in August than that produced in the corresponding month of the previous year. This increase together with some additional quantities diverted from the fluid sales, contributed to a 14 per cent advance in the creamery butter make and a 10 per cent increase in dairy butter. Reports from dairy correspondents showed a 2 per cent decline in cow numbers in August as compared with the same month last year. This reduction in numbers was offset by an equal gain in the percentage of cows milked. The increase in milk production may be attributed, however, to a substantial increase in the yield of milk per cow.

The precipitation in September was about the same as last year, but temperatures were lower with fewer hours of sunshine than was recorded in the same month of 1946. Pastures were quite satisfactory in September, averaging 90 for the province as a whole as compared with 81 a year ago.

Ontario: The quantity of milk produced on farms in August (see Table),0 was $3\frac{1}{2}$ per cent greater than that of August, 1946. With an increase of 10 per cent in the creamery butter make the quantity of milk represented in factory production showed a net gain of $6\frac{1}{2}$ per cent over the same month a year ago. The amount so used represented about two-thirds of the total milk supply. A reduction of 4 per cent in fluid sales in comparison with the corresponding month of the previous year provided some additional quantities of milk for manufacturing. Although the numbers of milch cows reported to be on farms were almost $2\frac{1}{2}$ per cent less than those reported in August, 1946, there was a slight increase in the percentage being milked. Freshenings also advanced and the milk production per cow was substantially higher than a year ago.

Weather conditions in September were generally quite favourable for dairying, with unusual temperature extremes. The first part of the month was quite warm while the latter part was cool with heavy frosts. At Ottawa, temperatures averaged about normal $(58\frac{1}{2}\text{ degrees})$, with $4\frac{1}{2}$ inches of rain and 196 hours of sunshine. There were three or four heavy frosts, the heaviest occurring on September 23, when the temperature at Ottawa fell to 24 degrees, the lowest September temperature on record. With somewhat more rain than that recorded a year ago, pasture conditions for the province were exceptionally good, showing an average of 94 as compared with 67 in September, 1946.

Manitoba: An increase of $l\frac{1}{2}$ per cent in the production of milk was recorded in August as compared with the same month of the previous year. This represented a marked improvement, a reduction of $2\frac{1}{2}$ per cent having been indicated in the figures given for the month of July. This increase in supply, combined with a reduction of $4\frac{1}{2}$ per cent in fluid sales provided more milk for dairy factories, representing an increase of about 3 per cent over the August deliveries in 1946. There were fewer milch cows reported, however, but the 2 per cent reduction in numbers was partially offset by an increase in the percentage of cows being milked.

Reports from observers indicate that pasture conditions were exceptionally satisfactory in September, being rated at 98 as compared with 86 a year ago. Heavy precipitation was recorded during the month, and quite heavy frosts during the latter part of September caused damage to late crops and pasture grass. Harvest fields are now cleared for dairy herds, but fields were not available as early as they were a year ago. Mill feeds are being quoted about \$7.50 per hundred above prices of the previous year.

Saskatchewan: Milk production in this province declined almost 2 per cent as compared with that of August, 1946. This was reflected in the deliveries to

⁽¹⁾ Condensed skimmilk is not separately listed in import returns. Condensed milk designated as such shown in trace reports consists principally of condensed whole milk products.

⁽²⁾ Not available at date of publication. (3) Less than 500 lbs.

factories and in a decline of 3 per cent in fluid sales. The numbers of dairy cows on farms was reduced by a little more than 3 per cent from last year as compared with a 4 per cent reduction in the previous month. It is also encouraging to note that there was a substantial advance in the percentage of cows being milked.

A considerable amount of rain fell during September and temperatures were somewhat below normal. The increased moisture kept the pastures in a verdant condition and produced a heavy growth on summer fallows and narvest fields. It is apparent, therefore, that there will be plenty of forage for dairy herds during the autumn, which should have a favourable effect on dairy production.

Alberta: Total milk production in Alberta declined 3 per cent in August and the deliveries to dairy factories fell nearly $4\frac{1}{2}$ per cent below those of the same month in 1946. Less milk was sold for fluid purposes, but more was consumed in farm homes. Dairy butter production showed an increase of 3 per cent over the corresponding month of the previous year. The holdings of milch cows appear to be fairly constant at approximately $1\frac{1}{2}$ per cent below those of August, 1946. This decline, however, was balanced by an increase in the percentage being milked.

September was a cool, cloudy month with heavy precipitation in the form of both rain and snow. Twenty-seven inches of snow were recorded at Lethbridge and 3.4% inches of rain as compared with less than 2 inches a year ago. A heavy frost was recorded on September 17. On account of the abundant supplies of after-harvest-forage, it is expected that milk production will be maintained at a point close to the 1946 level.

British Columbia: The milk production estimate for August revealed an increase of 1½ per cent over the same month last year, and with a 2 per cent decline in fluid sales, the deliveries of milk to factories were 6 per cent greater than those of a year ago. More milk was used on farms. Dairy butter production moved up 2½ per cent and the quantities of milk fed to livestock showed an advance of 4 per cent. Cow numbers as reported in August were less than those held on farms a year ago, but with the increase in the percentage milked, the situation was practically unchanged. The advance in milk production was due to an increase in the milk production per cow. September was relatively dry with cool weather at nights. Pastures were only fair, but in most districts the supply of forage was adequate. For the province as a whole, the average condition of pastures was about the same as last year. Labour is still scarce and with the increase in feed costs following the removal of ceiling prices, a reduction in the profits from dairying would seem to be indicated.

DAIRY CATTLE NUMBERS

The results of the June 1 survey for cattle released on October 11 and reviewed in the table below reveals a fractional decline in the numbers of milch cows on farms as compared with a year ago. This decrease was reflected in the figures for all provinces except Quebec and Ontario where numbers advanced 2 per cent and 0.2 per cent, respectively. The holdings of dairy cows which reached the peak in 1945 declined at a much more rapid pace during the course of the past year than in the twelve-month period from June to June, 1945-1946. The opposite situation, however, was revealed in the holdings of dairy heifers. Between 1945 and 1946, a decrease of 52 per cent was recorded in the twelve-month period, 1946-47. Whereas, between June 1, 1946 and June 1, 1947 there was an increase of one-half of one per cent. The figures given for calves include both beef and dairy types, but since the proportion used for dairying varies little from year to year, it indicates the numbers likely to be available for replacement purposes. While a decrease of 3.5 per cent was recorded in the 1946 report, an increase of nearly 2 per cent was revealed in the holdings of calves on farms at June 1, 1947, as compared with those shown at the same date in 1946. Thus, based on the data shown for both heifers and calves, there is some evidence that an upward swing in dairy cow numbers may be expected in the course of the next two years.
