MONTHLY INDEXES OF THE PHYSICAL VOLUME OF BUSINESS.

OTTAWA, NOVEMBER, 1932.

Dominion Statistician: R. H. Coats, B.A., F.S.S. (Hon.), F.R.S.C.

Chief, Branch of General Statistics: S. A. Cudmore, M.A., F.S.S.

Assistant on Business Statistics: Sydney B. Smith, M.A.

To supply the need for more adequate information relating to the trend of production, a revision of the indexes of the physical volume of production covering the post-war period has recently been completed by the Dominion Bureau of Statistics. Current data are given in the Monthly Review published by the Bureau. A progress report including 83 indexes and relatives is presented for each month from January 1919 to September, 1932, in the present bulletin.

The index number, first popularized by the London Economist during 1869 in connection with a study of wholesale prices, is now filling an important place as a device for measuring the trend of economic conditions. It is safer to base one's impression of the current trend upon a comprehensive index embracing a wide range of economic factors than upon any limited group of components that necessarily fluctuate according to particular influences. An index number reflecting the general trend of production has a considerable advantage over the individual factor as a background for the determination of policy by the investor or business executive.

Index numbers of wholesale prices and of the cost of living were introduced many years ago, and are now widely recognized as business barometers of importance. In recent years, the use of the device has been extended to the field of production, where it measures the general trend of business operations. The diversity of fluctuation among the factors of physical volume demonstrates the necessity of composite indexes.

In the interpretation of the economic trend, production factors play a most important part. In a very special sense prosperity and depression are closely correlated in a profit economy with the fluctuations in the volume of production, and prosperity is regarded by some authorities as a function of the degree in which personnel and industrial equipment are employed. If this definition is accepted, it follows that production data are essential to any thorough-going attempt to appraise the economic trend. The high regard for employment statistics is partly due to the close correlation which must always exist over short periods between general employment and production.

The trend of the industrial output is one of the essential factors in the measurement of economic progress. In the work of analysis, composite production data occupy a central position. Through an examination of the relationship of the business index with other fundamental economic factors, historical sequences may be established, that will prove of the greatest value in tentative forecasting. Among the main factors that are comparable in this connection are wholesale prices, money rates, bond yields, bank deposits, and common stock prices. Better results may be obtained by a comparative analysis of these factors than by an isolated study of the trend of any one of them.

Comparison with the Old Index

Monthly production indexes were first published by the Bureau in 1926, covering the post-war period and appearing month-by-month in the Monthly Review of Business Statistics. The present series supersedes the original compilation and its compilation has involved a thoroughgoing revision in material and method. The old system was based on the monthly average for the six-year period from 1919 to 1924 and was computed by the averaging of weighted relatives. In the new system the average for the year 1926 was taken as the base and the aggregative method was adopted for the compilation. The list of included factors was also greatly extended.

The Problem of Seasonal Variation

In bygone days considerable error crept into the interpretation of economic statistics through lack of analysis. No account, for example, was taken of the seasonal factor which for climatic reasons is specially important in Canada. Monthly variations that tend to recur from year to year in a somewhat regular manner are regarded as due to seasonal causes. Practically every factor coming under review showed fluctuation from seasonal tendencies. The elimination of this factor involved two steps, first, the compilation for each factor of seasonal indexes measuring the extent of the variation, and secondly, the division of the original data by these indexes, to remove the seasonal element. The month-to-month link relative median method, including the elimination of the long-term trend from the seasonal indexes, was used in this connection. The seasonal indexes were determined from the period from January, 1919, to December, 1930. For the old series the averaging method was used and the indexes were determined from the experience of the period lasting from 1919 to 1925.

The Revision of the Index

While several factors have been dropped from the recent compilation which had been included in the old, a larger number were added, resulting in a considerably greater range upon which to base the calculations. The index of mineral production was extended to include lead production and bauxite imports, resulting in a list of nine factors compared with seven in the old compilation. The old index of manufacturing production was based on 16 factors. Cold storage holdings of butter and cheese were not retained for the new index. The additions to the new index were,-production of oatmeal, rolled oats and corn flour, cheese and canned salmon exports, release of leaf tobacco, cigars and cigarettes, boot and shoe production, cotton yarn imports, exports of woodpulp and shingles, iron and steel imports, and coke production. The net result is that the index of manufacturing production is computed from 29 factors instead of from 16 as in the old compilation. The index of construction is dependent on the trend of contracts awarded and of building permits rather than on the value of awarded contracts alone as in the old series.

In the distribution group, bank debits and shares traded, greatly influenced as they are by speculative tendencies, are dropped from the compilation.

No change was made in the factors contributing to the index of agricultural marketings, while lard and veal were added to the list of factors determining the trend of the index of cold storage holdings.

Description of the New Index

The current system is built up from 63 original factors, of which 45 are included in the index of the physical volume of business and 18 in the indexes of agricultural marketings and cold storage holdings. In the old compilation there were 30 factors contributing to the business index and 16 to the indexes of agricultural marketings and storage holdings, making a total of 46 factors.

The resulting index of the physical volume of business is regarded as a measure of the broad forces determining the swing from prosperity to depression and the ultimate recovery. Each of the factors entering into that index moves in its own individual way subject to a variety of influences. Yet it does not act in isolation. Expansion or contraction in any particular line affects other factors and is affected by them. Out of this multiplicity of minor movements, the business index is intended to portray the broad trend which characterizes the economic system as a whole.

The variation in crop yields due mainly to weather conditions, the change in fundamental interest rates and the variation in the demand for plant and equipment are among the influences affecting the trend of industrial activity. These influences may not be necessarily constructive during the same period. Consequently, it is necessary that the selection of factors should be so representative as to reflect the divergent movements of this kind. Trade depressions and revivals do not affect all industries at the same time or in the same way, so that a business index should include factors from all important industrial groups. Data are not sufficiently complete to permit a full system of grouping on the basis of the three types of classification according to component material, origin and purpose. The classification adopted is largely industrial, affording an opportunity for comparison between the general trend and the trend of particular industries and industrial groups. The business index is based on industrial production and distribution. Industrial production consists of manufacturing, construction and electric power. Indexes for foodstuffs, live stock, slaughtering, tobacco, textiles, wood and paper, and iron and steel are derived from the factors listed under manufacturing production. The section dependent upon the sale, receipt and storage of agricultural products is divided into agricultural marketings and cold storage holdings. Agricultural marketings in turn are based on grain receipts and live stock sales.

The old system of production indexes was based on the monthly average for the six-year period from 1919 to 1924. The adoption of 1926 as the base year for the new system was due to several considerations. The reference to a single year creates a more definite impression than would be conveyed by the use of an average from a longer period. Production in 1926 was about midway between the low levels of the primary post-war depression and the zenith of the industrial expansion in 1929, and were consequently from this viewpoint an average year. Again, as the indexes of employment, banking, commodity and security prices published by the Bureau are based on 1926, it is desirable for purposes of comparison that the production indexes should be similarly constructed.

The method of weighting was also distinctly altered. The gross value of production in the case of primary industries and the value added in the case of secondary industries was the basis of the weighting system of the old index. The revised index is weighted by the prices of the commodities which enter into the compilation. Each factor was multiplied by the average price during 1926. The resulting products were added to give, at the average prices of 1926, a total value of the production of the included items during any given month.

This suggests the method of computation. The production value for any month compiled in this way is expressed as a percentage of the average value during the base year, 1926. The formula used is the aggregative, $\frac{\sum P_0 q_1}{\sum P_0 q_0}$, widely regarded as being one of the most practical of the formulae available for the purpose. The aggregative method is free from statistical bias inherent in averages of relatives, is easy to comprehend and simple to calculate.

Several factors expressed in terms of dollars were adjusted for the purpose of placing them on a volume basis. By means of appropriate indexes of prices and costs, the original data of imports, exports, imports of iron and its products, construction contracts awarded, and building permits were adjusted in this way. The index of the cost of construction was constructed by the weighting of indexes of prices of building materials and of wages in the building trades. The index of bank debits was also adjusted by dividing it by the index of the general price level, computed from indexes of the cost of living, wholesale prices and wage rates.

The aim of this bulletin is to make the business indexes currently published by the Bureau, more accessible, more intelligible, and therefore, more useful. A list of the relatives and indexes prepared in this connection, outlining the weighting system and serving as a table of contents, is given below. A chart showing eleven of the principal indexes from 1919 to the present appears on page 7. The main body of the bulletin is devoted to a presentation of 83 relatives and indexes by months from January, 1919, to September, 1932.

	Weight	Page		Weight	Page
Physical Volume of business	181,324	8	Iron and steel	16,483	21

OTTAWA, NOVEMBRE 1932.

Statisticien du Dominion: R. H. Coats, B.A., F.S.S. (Hon.), F.R.S.C.

Chef de la Section de la Statistique Générale: S. A. Cudmore, M.A., F.S.S.

Adjoint (Statistiques Économiques). S. B. Smith, M.A.

Pour répondre au besoin d'informations plus adéquates sur la marche de la production, le Bureau Fédéral de la Statistique vient de compléter une révision des indices du volume physique de la production de la période d'après-guerre. Les données courantes paraissent dans la Revue Mensuelle de la Situation Économique, publiée par le Bureau. Le présent bulletin donne un rapport intérimaire couvrant 83 indices et leurs dérivés, par mois, de janvier 1919 à septembre 1932.

Le nombre-indice, introduit et popularisé par l'"Economist," de Londres, en 1869, dans l'étude des prix de gros, joue maintenant un rôle important comme unité de mesure dans l'orientation des conditions économiques. Il est plus prudent de baser son impression de la direction du courant sur un indice compréhensif embrassant une grande diversité de facteurs économiques plutôt que sur un groupe d'éléments dont les fluctuations subissent nécessairement des influences particulières. Un nombre-indice reflétant la marche générale de la production a un avantage considérable sur le facteur individuel en tant qu'arrière-plan pour déterminer le programme soit de l'épargnant soit du négociant.

Les nombres-indices des prix de gros et du coût de la vie ont été introduits il y a plusieurs années, et sont maintenant généralement reconnus comme d'importants baromètres des affaires. En ces dernières années leur emploi s'est étendu à tout le domaine de la production où ils mesurent la tendance générale des opérations commerciales. La diversité des fluctuations entre les facteurs du volume physique démontre la nécessité d'indices composites.

Les facteurs de production jouent un rôle important dans l'interprétation de la marche économique. Dans un sens très spécial, la prospérité et la dépression sont en relation étroite dans l'économie des profits avec la fluctuation du volume de la production, et certaines autorités considèrent la prospérité comme une fonction du degré d'emploi de l'outillage humain ou industriel. Si cette définition est acceptée, il s'en suit que les données de la production sont essentielles à toute tentative de mesurer à fond le mouvement économique. L'importance attachée aux statistiques de l'emploi est due partiellement à l'étroite relation qui doit toujours exister sur de courtes périodes entre l'emploi général et la production.

La marche de la production industrielle est un des facteurs essentiels dans la mesure du progrès économique. Les données composites de la production occupent une position centrale dans le travail de l'analyste. En examinant la relation entre l'indice des affaires et d'autres facteurs économiques fondamentaux, des séquences historiques peuvent être établies qui seront de la plus grande valeur dans le calcul des prévisions. Les prix de gros, le loyer de l'argent, le rendement des obligations, les dépôts des banques et le cours des actions ordinaires sont les principaux facteurs sur lesquels cette comparaison est applicable. De meilleurs résultats peuvent être obtenus par une analyse comparative de ces facteurs que par une étude isolée du cours de l'un ou de l'autre.

Comparaison du vieux indice

Des indices de la production mensuelle ont été publiés pour la première fois par le Bureau en 1926, couvrant la période d'après-guerre et paraissant chaque mois dans la Revue Mensuelle de la Situation Économique. La présente série remplace la compilation initiale qui est revisée à fond, tant dans sa méthode que dans sa base. Le vieux système était basé sur la moyenne mensuelle de la période de six ans 1913-1924 et elle était calculée en établissant une moyenne des éléments pondérés. Dans le nouveau système, la moyenne de 1926 est prise comme base et la méthode agrégative est suivie dans la compilation. La liste des facteurs inclus est aussi grandement allongée.

Le problème des variations saisonnières

Il s'est glissé autrefois une large marge d'erreur dans l'interprétation des statistiques économiques vu le manque d'analyse. Par exemple, on ne tenait pas compte du facteur saisonnier qui, pour des raisons climatériques, est spécialement important au Canada. Des variations mensuelles qui tendent à se répéter d'année en année, d'une manière à peu près régulière, sont regardées comme dues à des causes saisonnières. Presque chacun des facteurs pris en considération montre des fluctuations provenant de tendances saisonnières. L'élimination de ce facteur comprend deux opérations; d'abord, la compilation pour chaque facteur des indices saisonniers mesurant l'étendue de la variation, et deuxièmement, la division de ces données originales par ces indices pour éliminer l'élément saisonnier. La méthode de médiane relative par la juxtaposition de mois en mois, après l'élimination de la tendance à long terme dans les indices saisonniers, a été employée à ce sujet. Les indices saisonniers ont été calculés depuis janvier 1919 à décembre 1930. La méthode des

Moyenne a été suivie dans les vieilles séries, les indices étant constitués par les faits constatés entre 1919 et 1925.

La révision de l'indice

Bien que plusieurs facteurs de la vieille compilation aient été omis dans la nouvelle, un plus grand nombre d'autres y ont été ajoutés, et comme résultat les calculs reposent sur une plus grande variété de sujets. L'indice de la production minérale a été élargi de manière à comprendre la production du plomb et les importations de manganèse, ce qui lui donne aujourd'hui neuf éléments au lieu de sept dans la vieille compilation. Le vieux indice de la production manufacturière était basé sur 16 facteurs. Dans le nouvel indice, les entreposages de beurre et de fromage ont été mis de côté et les nouveaux facteurs sont la production de farine d'avoine, d'avoine roulée et de farines de maïs, les exportations de fromage et de saumon en boîte, les dédouanements de tabac en feuilles, cigares et cigarettes, la production de chaussures, les importations de filés de coton, les exportations de pulpe de bois et de bardeaux, les importations de fer et acier et la production de coke. Comme résultat, l'indice de la production manufacturière repose sur 29 éléments au lieu de 16 dans l'ancienne compilation. L'indice de la construction comprend le mouvement des contrats et celui des permis de bâtir, au lieu de la valeur des contrats seulement comme dans l'ancienne série.

Dans le groupe de la distribution, les débits des banques et le nombre de titres changeant de portefeuilles ont été éliminés de la compilation parce qu'ils sont trop grandement influencés par leur tendance spéculative.

Aucun changement n'a été fait dans les facteurs contribuant à l'indice du marché agricole, et le bœuf et le veau ont été ajoutés à la liste déterminant l'indice des entreposages frigorifiques.

Description du nouvel indice

Le système courant repose sur 63 facteurs dont 45 sont compris dans l'indice du volume physique des affaires et 18 dans l'indice du marché des produits agricoles et des entreposages frigorifiques. Dans la vieille compilation il y avait 30 facteurs contribuant à l'indice des affaires et 15 entrant dans l'indice du marché agricole et des entreposages frigorifiques, faisant un total de 45 facteurs.

L'indice du volume physique des affaires qui en résulte est considéré comme la mesure des forces vives poussant le balancier de la prospérité à la dépression et à la reprise des affaires. Chacun des facteurs entrant dans cet indice se meut dans son propre orbite et subit une grande variété d'influences. Cependant sa marche n'est pas isolée. L'expansion et la contraction de toute ligne particulière affectent d'autres facteurs ou en sont affectées. Réflétant cette multiplicité de mouvements mineurs, l'indice des affaires a pour but de photographier l'orientation générale qui caractérise le système économique dans son ensemble.

La variation du rendement des récoltes, due en plus grande partie à la température, le changement dans le loyer fondamental de l'argent et la variation de la demande pour outillage sont parmi les influences affectant la marche de l'activité industrielle. Ces influences ne sont pas nécessairement constructives pendant la même période. En conséquence, il est nécessaire que la sélection des facteurs soit assez représentative pour refléter les divergences de mouvements. Les dépressions et les reprises commerciales n'affectent pas toutes les industries en même temps ou de la même manière, de sorte qu'un indice des affaires doit inclure des facteurs de tous les groupes industriels importants. Les données ne sont pas suffisamment complètes pour permettre un système entier de groupement sur la base de trois types de classification, d'après les substances composantes, l'origine et la destination. La classification adoptée est plutôt industrielle, permettant de comparer entre la tendance générale et la tendance des industries particulières et des groupes industriels. L'indice des affaires est basé sur la production industrielle et la distribution. La production industrielle embrasse les mines, les manufactures, la construction et l'énergie électrique. Les indices de l'industrie alimentaire, du bétail, des abattoirs, du tabac, des textiles, du bois et papier, du fer et acier sont tirés des facteurs entrant dans la production manufacturière. La section dépendant de la vente, de l'arrivée et de l'emmagasinage des produits agricoles est divisée en deux: le marché des produits agricoles et les entreposages frigorifiques. À son tour, le marché des produits agricoles est basé sur les arrivages de grain et les ventes de bestiaux.

L'ancien système d'indices de production était basé sur la moyenne mensuelle des six années 1919-1924. L'adoption de 1926 comme année de base dans le nouveau système est due à plusieurs considérations. En référant à une année spécifiée il est possible de créer une impression mieux définie que si l'on emploie une moyenne répartie sur une plus longue période. La production de 1926 était à peu près à mi-chemin entre les bas niveaux de la dépression primaire d'après-guerre et du zénith de l'expansion industrielle de 1929, et pour cette raison elle est acceptée comme une année moyenne. De plus les indices de l'emploi, des opérations bancaires, des prix des denrées et des valeurs mobilières publiés par le Bureau sont sur l'échelle de 1926, et il est désirable, pour fins de comparaison, que les indices de la production reposent sur une base semblable.

La méthode de pondération a aussi été distinctement changée. La valeur brute de production dans le cas des industries primaires, et la valeur ajoutée dans le cas des industries secondaires est la base du système de

pondération du vieil indice. L'indice revisé est pondéré par les prix des marchandises entrant dans la compilation.

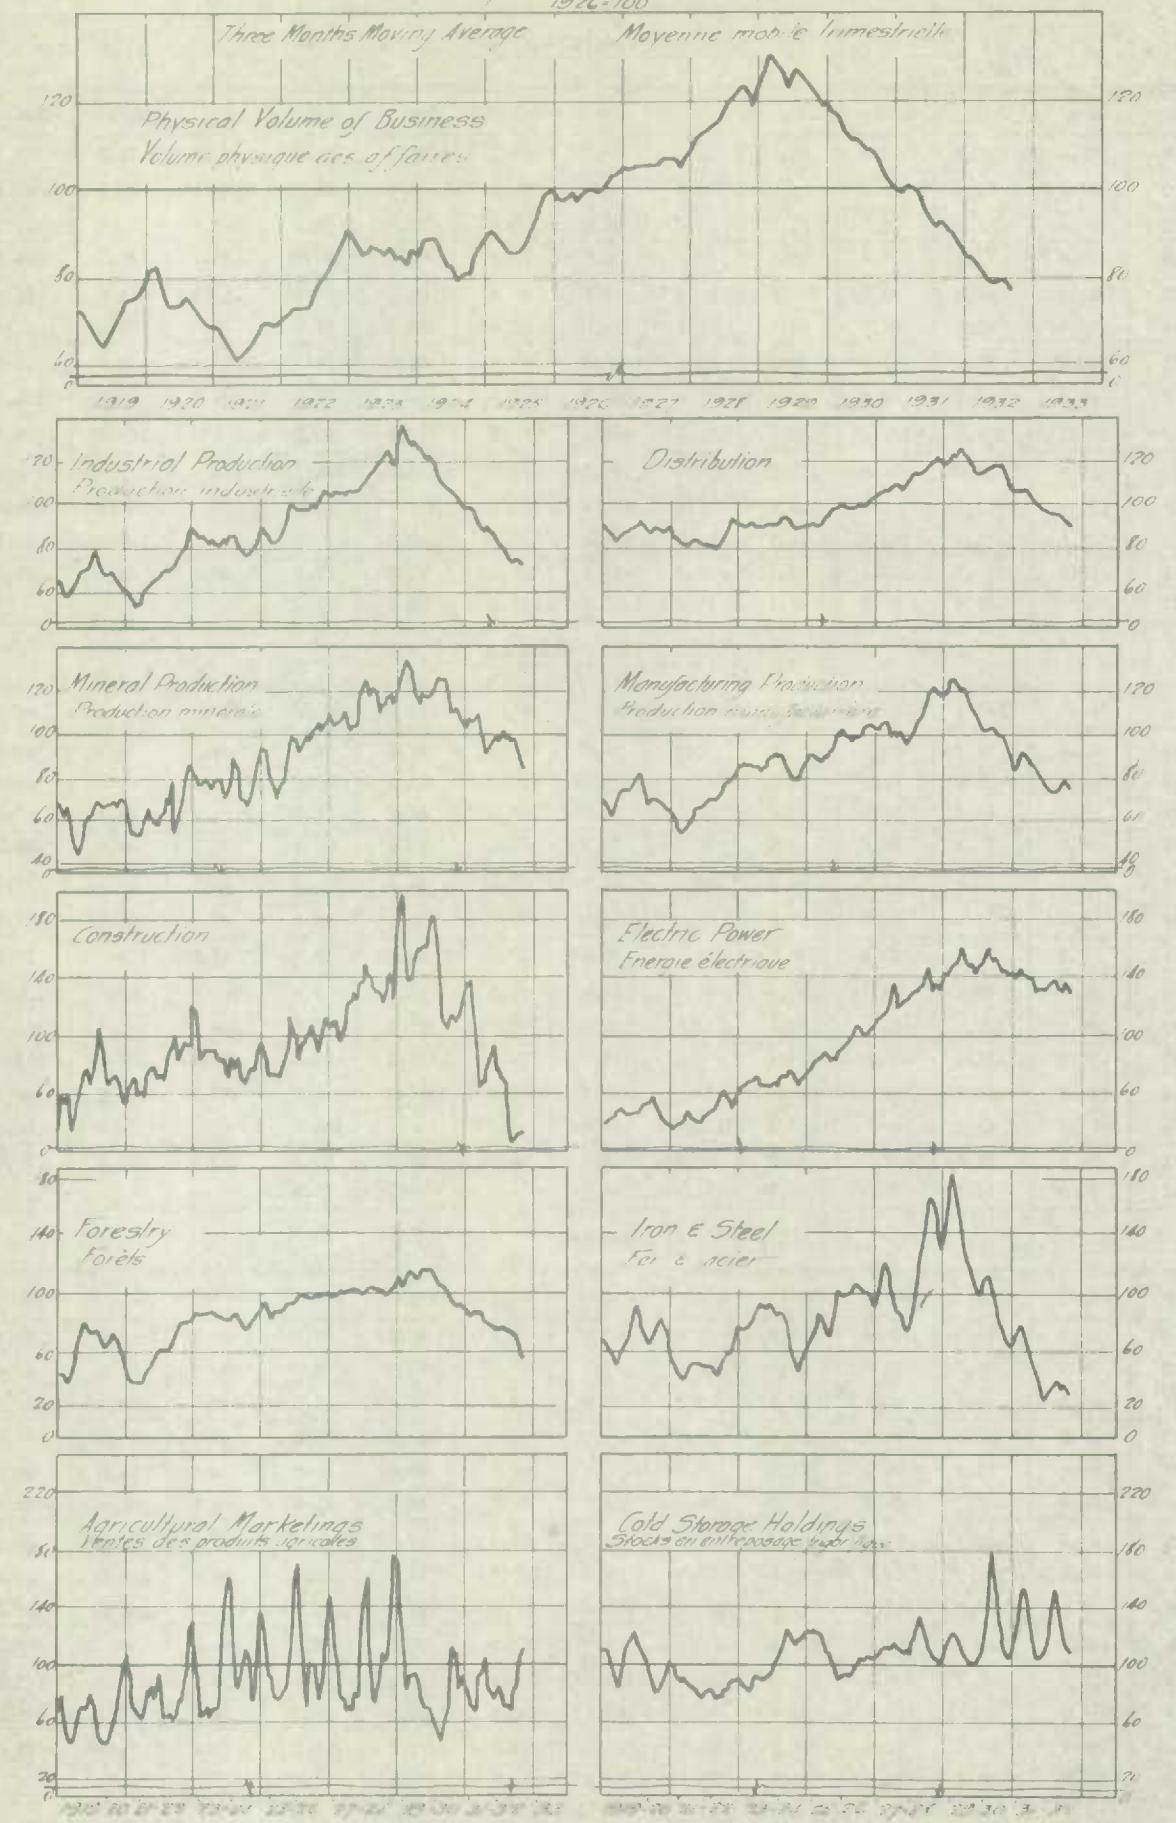

Chaque facteur a été multiplié par le prix moyen de 1926. Les produits qui en résultent ont été additionnés pour donner, au prix moyen de 1926, une valeur totale de la production de chaque item inclus pendant tout mois quelconque.

Le calcul se fait par la méthode suivante: La valeur de la production de tout mois quelconque calculée de cette manière est exprimée en pourcentage de la valeur moyenne durant l'année de base, 1926. La formule employée est l'agrégative $\frac{\sum P_0 q_i}{\sum P_0 q_0}$ considérée comme l'une des plus pratiques et celle la plus généralement employée comme l'une des plus pratiques et celle la plus généralement employée pour cette fin. La méthode agrégative est exempte des travers statistiques inhérents aux moyennes relatives et elle est facile à comprendre et simple à calculer.

Une liste des dérivés et des indices préparés à cette fin, donnant un aperçu du système de pondération et servant en même temps de tableau des matières paraît ci-dessous.
