## EXPORT AND IMPORT PRICE INDEXRS: JULY, 1945 TO JUNE, 1950

This new monthly record of export and import price indexes is on a post-war base and uses a post-war weighting system $(1948=100)$. It may be used to deflate trade values in order to derive volume comparisons. The series will be kept up to date henceforth and, beginning in 1951, will be published each month in Trade of Canada" together with derived quantity indexes. A summary table of value indexes and the derived quantity indexes is given in the attached appendix.

The price indexes begin at the end of the war and show an almost continuous price rise through the next three and one half years. The amount of the increase from July, 1945 to January, 1949, was 41.7 per cent for export prices and 38.7 per cent for import prices. During the same period, Canadian domestic price levels as measured by the general wholesale price index rose 52.3 per cont. There then followed a short period of decline in both export and import price indexes which lasted until September of 1949, when the world-wide re-alignment of currencies took place. It was recognized then that it would take some time for the effects of revaluation to disclose themselves. This expectation is borne out by the behaviour of the new export-import price indexes. They began a gradual climb in September, 1949, which continued with minor exceptions through the next nine months.

The amount of the price increase roughly approximated the Canadian nine per cent devaluation of September, 1949. Export prices rose from 100.0 in September, 1949 to 107.7 in June, 1950. Import price indexes rose from 101.4 in September, 1949 to 109.3 in June, 1950. Apparently, the larger relative devaluations of the United Kingdom and the European countries did not affect the levels of Canadian export and import prices to as great an extent as the effects of Canadian devaluation vis-a-vis the United States. A summary table and a chart of these price movements are shown on pages 5 and 6 and the subgroups and selected main items are given in following tables.

## Method of construction of indexes

The price series are a cambination of unit value series derived from trade statistics and of specified price series from existing wholesale and retall price records of Canada and the United States. The specified price series are used when the necessary coverage and representativeness of trade items are lacking. Caneda's import and export trade statistics are valued as declarca, approximately f.o.b. inland point of shipment in both Canada and in the country of origin.

The unit values have been obtained by dividing quantities into declared values for those items in the trade statistics which show standardized quantity units sufficiently well designated to prevent change in physical content or description from influencing the price record. The declared value of newsprint, for instance, divided by the number of tons exported, gives an average price per ton received by the exporter, exclusive of freight and other charges.

Insofar as these indexes have been designed primarily for use in deflating merchandise trade statistics of declared values, the emphasis is placed on unit values. Where the cetegory is not well defined or if there is no quantity unit given in trade statistics, other price sources have been used. Certain items of machinery listed in trade statistics with a quantity unit of "number" are not measureable in price, for example, because of the variable size and description of the machines in the category. For these and other similar commodities, therefore, wholesale or other price series are substituted.

It must also be pointed out that unit values cannot be expected to move in exactly the same manner as spot prices. One main reason for this is that the price may vary according to the destination. Wheat for example, was sold to the United Kingdom at $\$ 2.06$ per bushel on March 25, 1950; to International Wheat Agreement countries at $\$ 1.98$ and to other countries at $\$ 2.225$ per bushel. The average price in the trade statistics during March was $\$ 2,094$, a weighted average of all grades and all destinations. The main point is that even though the above spot prices were to remain constant, the varying amounts shipped to the different destinations would cause the unit value to change from month to month. Another example may be given for newsprint. Although the spot price remained at $\$ 100$. ( $\$ 110,00$ Canadian) per short ton delivered in New York, the price recorded on export declarations averaged $\$ 97$ Canadian per short ton. As these declarations exclude inland freight and handing charges, unit values varied as points of shipment, destinations, and individual contract arrangements varied. The main advantage of this from the present standpoint is that the recorded dollar values also very, so that when the variable price is divided into them, a proper measure of quantity change is derived.

In all cases where published wholesale and retail price series have been utilized, which in their original form are based either $1926=100$ or $1935-39=100$, mechanical conversions to a $1948=100$ base have been calculated. In some cases, the separate items of composite indexes have been reaweighted by trade statistics weights relating to 1948. United States' price series incorporated into the import record, furthemore, have been multiplied by a rate of exchange index referring to the same base period in order to convert them to Canadian funds. By these means all individual series which make up the aggregates have been reduced to comparable terms of reference.

Certain wholesale price series have been posted ahead in the monthly price indexes both as an expedient to enable current months to be computed without undue delay and in order to give recognition to the effects of contracts and the tendency for shipments to take place at a later date.

Some further difficulties in the way of perfecting an export and import price record may be enumerated as follows:

Valuntion of trade statistics:- Although it is not a source of major difficulty in the period covered by these indexes, customs' evaluators have in the past sometimes set values for imports which are not the same as the cost to the importer. There has been in addition, somewhat less incentive to accurate declaration of imports which are free and of exports, since no duty is involved. However, most of the series selected for the samples of trade items are free from this defect. A further difficulty could occasionally result from the circumstance that imports are valued at official rates of exchange whether or not these are appropriate to the actual transaction. Unit valuations in this latter connection will be defective as true measures of price. Nevertheless, in deflation of trade statistics the resulting differences between market values and declared values are a part of both the values (or value indexes) and the price indexes so that the defects are removed from the resulting quantum quotients.

Qualitative differences in temporal comparisons:- Specific items or articles which enter into trade may change quality over a time period. Some of this type of error has been removed by the use of specified price series. Where unit value series are used, however, any undiscovered quality change becomes a part of the price index, and does not show up as it should in resulting quantity indexes.

## Classification:

The existing classification of the trade statistics has been followed in principle, and as closely as possible in practice, by these price indexes. However, in order to facilitate the selection of price series which would be representative of larger groups, however, certain adjustments have been made. The groups of the trade statistics usually designated as agricultural and vegetable products and as animals and animal products have been combined into Group 1, agricultural and other primary products; with a sub-group of rubber and its products transferred to the miscellaneous group of products largely because of its synthetic rubber content. Ships of iron and steel have been transferred to iron and steel and their products; plumbing and heating equipment of the non-ferrous metal type iransferred from iron and steel to non-ferrous metals and their products; phosphate rock transferred from non-metallic minerals to the fertilizer sub-group of chemicals and fertilizer; and imports of "articles, the property of the Imperial Government and to remain the property of such government and articles for the personal use of officers and men on board ship" deducted from the total of imports entered for consumption. Temporary trade for exhibition and competition and gold are already excluded from the statistics of merchandise trade in the years and months of these price indexes. These adjustments have been made to improve group and aggregate comparability over the time period.

A useful distinction when the financial aspects of merchandise trade statistics are being considered, is the one between "commercial transactions" and "special and non-commercial transactions". The former are negotiated by the familiar price media whereas the latter are not usually subject to this criterion. The "special and non-commercial" trade transactions have been separated in part (b) of Groun VIII of these price indexes. Items concerned are a small proportion of the import and export trade and are nearly all identifiable. They have been segregated to the extent of the following list of short titles:

## Exports of special and non-commercial articles:

Settlers' effects;
Donations and gifts:
Contractors outfits;
Motion picture films.
Imports of special and non-commercial articles:
Settlers' effects; Effects left by bequest;
Charitable donations;
Casual donations;
Presentations for lifesaving;
Articles for the use of the Governor-general;
Articles for the use of representatives of commonweal th and foreign goveraments;
Incidental purchases by Canadians returning from other countries;
Cinematograph film positives;
Advertising and printed matter.

## Weignting

Each of the individual price series is weighted in the composite index by its percentage of the 1948 total value plus whatever imputation is due to it within its group to allow for unmeasured residual items in that group. By this method unmeasured
residuals are assumed to change price in a manner similar to that of the measured items. Group indexes are given their full value weight. Selection of series has been based largely on value importance but representativeness also has been taken into account. If items were large in value, an attempt was made to obtain prices for them. In some cases, series small in value but accurate in definition have been included as representative of a broader class. Approximately 80 per cent of the total value of exports of Canadian produce and over 75 per cent of the value of imports entered for consumption are represented by price series in this manner. Coverage within each group is in excess of 50 per cent in each case and in the major weight groups, considerably greater representation has been achieved. Summary tables of the weighting systems (tables 5 and 6) are given below, in whioh item titles, weights, and price source descriptions are recapitulated. A brief note concerning the mechanical methods of compilation is given in an appendia.

## Relation to previously published annual series

These export and import prico indexes are, essentially, an extension of annual series published earlier on a $1935-39=100$ base. The annual price indexes are not, however, equal to the sum of the twelve monthly indexes divided by twelve. The annual indexes are compiled directly from annual values and quantities. They qutomatically take into account the fact that prices may be different in months of heavy exports or imports. For example, the auturn wheat price is weighted heavily by auturn shipments and has, therefore, more influence than the price of wheat in other months of the year. Thus the annual averages are weighted averages and do not exactly equal a simple average of the monthly figures. The price indexes will be improved as refinement of trade classification develops and as new price sources become available. They are for this reason described as interim indexes.

Minor adjustments are made to these price indexes before they are used as deflators of commodity export and import totals as published in the current account of Canade's Belance of International Payments and the National Accounts. Such deflation requires, for example, the exclusion of special and non-commercial articles from the merchandise account for inclusion elsewhere in the current account framework; adjustments of declared values to estimated current market values; the addition of net warehousing data; and of resexports for which no price index is here included. The indexes in their present form are directly adapted to use in deflating totals published in Canada's trade statistics under the technical headings of: Exports of Canadian produce (excluding gold); and Imports entered for consumption (excluding gold).

Table 5: List of Comnodities, Code Numbers, Quantity Units, Value fieights and Price Nources used by Indexes of the Erices of Exports of Canadian Produce.

Agricultural \& Other

1. Primary Products
(a) Wainly edible:

Apples, Erains, livestock dairy and meat.

1. Apples
2. Barley
3. Oats
4. Rye
5. Wheat
6. Oatmeal and rolled oats
7. Wheat flour
8. Fresh beef \& veal
9. Dressed or undressed poultry
10. Bacon and hams
11. Cattle for improvement
of stock ---
12. Dairy and slaughter cattle

700 Lb . and over in weight 2040
13. Cheese
14. Condensed milk
15. Evaporated milk
16. Eggs in the shell

Sub-total
P1sh and Fishery Products:
17. Fresh halibut 2134
18. Fresh lobster
19. Fresh salmon
20. Fresh whitefish
21. Dried cod
22. Canned sea herring
23. Canned lobster
24. Ganned salmon

Sub-total
Other:
25. Kalt
26. Maple sugar Sub-totel

(2) Excluding: Imports of merchandise $\mathcal{C o r}$ the United $/ i n g d o m$ Government; temporary imports for exhibition and competition; monetary and nonmonetary gold.

Appendix: Notes on Frice Index Computetion and on Sumnery Tables of Value and Quanturn of Exports of Canadian Produce and of Canada's Imports entered for consumption.
(1) Price index computation:

The indexes of export and import prices are computed according to the familiar "Laspeyre" formula as base weighted averages of price relatives. The formula applied is as follows:

where Fn is the price of an individual commodity in a current period; Fo is the price of an individual commodity in the base period; and $Q_{0}$ is the quantity of an individual commodity in the base period.

York tables have been made up in two parts:
(a) Price records: A sample price worik sheet is made up as follows:

| Cormodities | Po | Qn | Pn Qn | Pn | In/Po |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $(1)$ | $(2)$ | $(3)$ | $(4)$ | $(5)=(4) \div(3)$ | $(6)=(5) \div(2)$ |

Column (1) contains the sample list of items wich ere exported or imported (as detailed in tables 5 and 6). Column (2), (3) and (4) contain base period prices, current quantities and current values, respectively, which have been obtained from the source dota. Columns (5) and (6) are calculeted as indicated. There price relatives aro obtained from other than unit value calculations, these are entered directly in Column (6).
(b) Frice index work tables: By means of the unit weighting systems (shown in tables 5 and 6), all calculations relevant to the price abgregate are performed on a single set of work tables, with sub-group calculations appearing at appropriate intervels. The headines of these tables follow:

| Commodities | $\text { Weights }=\frac{\text { PoQo }}{\text { a PoQo }}$ | $\mathrm{Pn} / \mathrm{Po}$ | Fn/Po.W | $\Rightarrow \frac{\frac{P_{n}}{P_{0}} \cdot W}{W}$ |
| :---: | :---: | :---: | :---: | :---: |
| (1) | (2) | (3) | $(4)=(2) \times(3)$ | $(5)=$ - 4 (4) $\div$ (2) |

The last column, in this case, is used to obtain group, sub-group and aggregate indexes according to the divisions of the stub. Colurn (1) contains a stub identical with the price record work sheet and the weighting system listings. Column (2) is obtained from Column (6) of the price records. The remaining columns are calqulated as listed.
(2) Value and quantum calculations

Deflation of a value index by a base weighted price index results in a currently weighted physical volume (quantum) index as follows:

The base weighted monthly price index is used since it is unaffected by month-tomonth changes in quantity. These latter are serious in Canadian trade. Wheat is, for example, shipped ah large volume in autumn months. If a currently weighted price index (Paasche formula) were used, a part of its variations from month-tomonth would be due to quantity chenges. In the extreme case, if there had been no price change whatsocver, a shift in quentities would cause the price index to change. Also the terms in the currently weighted price index would each be comparable with the base period, but there would be no month-to-month comparability. Even those indexes which average current and base period weights (Warshall. Edgworth and Fisher formulae for example) would contain a substantial clement of the above defect of current weighting.

In the method chosen, the quantum index resulting from deflation by a base-weighted price indox is itself currently weighted, but, in this case, the current weights are prices. Insofar as these are not subject to the same month-tomonth dispersion as quantities, it is not a matter of concern that the quantities are currently weighted. The above criteria, however, do not apply to annual indexes.

In addition to the above requirements for a proper use of weights, it is necessary to koep weighting systems up to date. Tests have shown that there are not serious differences in the behaviour of group or total indexes in a short period of two or three years. The 1948 weighting system used herein was considered most satisfectory in the post-war period to date. However, when 1950 trade statistics become ovailable, they will be examined with a view to establishing a new weighting syster and a new base if desirable. A new series could be linked at that time to the present one.

Canadian trade statistics require seperate price indexes to deflate each of the following three categories:

Exports of Canadian Produce; Exports of Foreign Produce;
Imports entered for Consumption.
No index of the prices of exports of foreign produce has been computed, however, so that in the sumary tables of value and quantum which follow (tables (i) and ii) only the first and the lest of these three categories have been deflated. (Exports of foreign produce are, in any case, seldom greater than 2 per cent of the total exports). Calculations shown in the two appended tables of value and quantum indexes are for the period covered by the price indexes - July, 1945 to June, 1950, and are made without adjustment for seasonal variation. Declared values have been adjusted in conformity with the price index concepts as indicated by footnotes to the tebles, however. Trade of the province of Newfoundland, of couree, onters all calculations of Cansdian trade as of April lst, 1949.

Table (i) Indexes of the Declared Values of Exports of Canadian Produce (1) and Canada's Imports entered for Consumption, (2) by months. July, 1945 to June $1950(1948=100)$
