## Acknowledgments

This paper was funded by both the Social Sciences and Humanities Research Council of Canada and the Economic Council of Canada as part of their research program on education in Canada. We thank participants in a workshop at the Economic Council of Canada, seminars at the University of Toronto and the University of Victoria at Wellington (New Zealand), a session of the Canadian Employment Research Forum 1991 meeting, a session of the 1991 Canadian Economics Association meetings. We also thank David Stager and Martin Dooley for useful comments; and Michel Briskin, Paul Butcher, Philippe Le Goff, Martine Hébert and Michelle Salvail for their research assistance. Part of this work was carried out while the author was a resident associate at the Institute for Policy Analysis, University of Toronto.

## Foreword

More than ever before, the skills of the Canadian workforce will determine individual and collective prosperity. Canadians face the challenge of competing in a globalized world economy. How successfully that challenge is met will be determined by the skills and the brains of the Canadian people.

The Economic Council has examined the Canadian education and training system and has identified some key areas where changes are needed. Our research and conclusions are summarized in the Council Statement, A Lot to Learn, published in April 1992.

This working paper, by François Vaillancourt, presents some of the background research to that Statement. It addresses the question of the rate of return to investment in education, both from the point of view of the individual and of society as a whole. Educational attainment has a strong influence on earnings. Indeed, after account is taken of the direct costs of schooling and of forgone earnings, the additional income from completing secondary school yields a rate of return of some 30 per cent for individuals.

This working paper presents estimates of private (individual) and public (social) rates of retum for a wide variety of schooling levels and fields of study. It also presents these estimates separately for men and for women. What is striking is the extent of variability in rates of return; even more striking is the finding that among the highest are returns to secondary school completion as compared to dropping out.

François Vaillancourt is a Professor in the Département des sciences économiques, and a Fellow of the Centre de recherche et développement en économique (C.R.D.E.), Université de Montréal.

The Economic Council of Canada working paper series presents research done for the Council to the public to stimulate discussion and comment. The papers are the personal responsibility of the authors and have not been reviewed and endorsed by the members of the Economic Council of Canada.

Judith Maxwell
Chairman

## Introduction

The purpose of this paper is to present private and public rates of return to schooling in Canada by level and by field of study or region of residence. Since rates of return to schooling are often used by both private and public decision makers in allocating resources, it is to be hoped that they will be of interest. The paper is divided into three parts. In the first part, the analytical framework use is discussed and results of previous studies reviewed. In the second part, the data and methodology are described. In the third part, results are presented and analyzed.

## Analytical framework and review of literature

The analytical framework for this study links eamings (labour income) and human capital, and assumes that individuals will acquire additional human capital only if the benefits of doing so are greater than the costs - both in forgone earnings and out-of-pocket expenses. These investment benefits are calculated in eamings, but should include other employment rewards (e.g., fringe benefits, pension rights, less hazardous employment) and nonemployment investment benefits such as higher productivity in home production, child-rearing, and good citizenship as well as consumption bencfits derived from education. As a result, the benefits from schooling, both from a private or public perspective, are underestimated in this paper. Since all the costs of schooling are included, the rates of retum thus obtained are a lowerbound estimate of the full returns to schooling.

Figure 1 summarizes the framework, using arbitrary numerical values. The $S$ curve represents the eamings profile of a secondary school graduate, and the $U$ curve represents the eamings profile of a university graduate (bachelor's degree level). The area labelled FE represents the earnings that a high-school graduate must forgo to attend university. In this figure, it is assumed that these are the only costs - the university student does not hold a summer/parttime job and does not incur out-of-pocket expenses. Altematively, one could interpret this as equating the out-of-pocket expenses and earnings of that student. One could also add a negative area (below the $X$-axis) to represent these costs (McMahon, 1987). The area labelled HE represents the difference between the earnings of the university graduate after graduation, and those of the high-school graduate from the age of graduation from university until retirement. The assumption that the (implied) intercept of $U$ is higher than that of $S$ is arbitrary as is the similarity in their slopes. The use of a common ending point to employment income at 65 years of age is also arbitrary, but it is common practice in studies of the return to education since it corresponds to social/hegal requirements. It probably leads to a small underestimation of the returns to education, since earnings at that age are heavily discounted.

## Figure 1

Earnings profile by level of schooling, secondary and unlversity levels

Once $H E$ and $F E$ are known, then one can calculate a rate of return, $r$, such that:
present value of university schooling $=0=\sum_{i=1}^{42} \frac{\left(U_{i}-S_{i}\right)}{(1+r)^{i}}-F E$ with 42 the number of years employed in this case.

Such a calculation may yield a positive, zero, or negative rate of return, depending on the size of $H E$ and $F E$.

There are three possible interpretations of $r$. The first is the pure human capital model. It assumes that individuals engaging in higher studies are identical in ability to those who do not, and that their studies allow them to acquire additional knowledge. Differences in earnings are then due to differences in human capital. The second option is the abilities approach, where individuals are assumed to differ in terms of ability. In that case, one may be calculating, in part, the returns to ability, with the importance of this return depending on the relative importance of ability and human capital in the determination of eamings. Finally, the third possibility, neglecting ability, is that schooling transmits no knowledge but is used as a screen by employers in the hiring process. In our opinion, the second option best represents reality. We must, however, establish what correction should be made for ability. As Stager $(1989,70)$ indicates, there are arguments to support both the view that university graduates would have eamed more than high-school graduates had
they not gone on to university, and the reverse, depending on how one views the nature of ability. We chose to present rates of return unadjusted for ability differentials and to leave the choice of correcting them to the reader.

Table 1 summarizes the data, methodology, and results of 13 studies of the rates of retum to schooling in Canada. Most use census data and calculate rates of return for high school or university in Canada as a whole. Only one study (Stager, 1989) uses the 1986 census data, but it is limited to Ontario.

## Methodology and data

## Earnings profiles

In this section, we describe the data that were available to us and then discuss the equations estimated with them. Men and women are treated separately, given that their eamings functions usually differ.

This study uses data from the 1986 Statistics Canada Census Individual Microdata File, available to researchers in January 1990. The data were prepared by drawing a 10 per cent sample of the long-form questionnaires that were sent to one fifth of all Canadian households, thus yielding a sample of 500,434 respondents or 2 per cent of the population. In the census, individuals who report earned income must be aged 15 and over. They number 392,680 ; of these, 260,327 report positive earnings (the sum of wages and salaries and net self-employment income). ${ }^{\text {? }}$

This last choice excludes from the sample employable individuals who have chosen to withdraw from the labour force, thus leading to an overestimation of the public rate of return. This is perhaps compensated for by including individuals who work part time by choice, which leads to an underestimation of the rates of retum. Note also that some studies (see Stager, 1968, 1989) correct eamings for differences in participation and mortality rates between schooling levels. Not including such corrections reduces the retums to more education, since participation rates go up and mortality rates go down with more schooling.

We study individuals in seven schooling levels that are arrived at by combining information on the highest level of schooling attained and the highest degree held (Table 2). We study seven fields of postsecondary study, regrouped from 12 specific fields. To ensure that the sample is adequate, the four Atlantic provinces were grouped into one region, the Allantic region, and Manitoba and Saskatchewan were grouped into one region, the Prairics. ${ }^{2}$

Souace Compiled by the author from various sources.

We estimate the following equation, using ordinary least squares:

$$
\begin{aligned}
\ln (\text { earnings })= & B_{0}+B_{1} \text { Age }+B_{2} \text { Age }^{2} \\
& +\left[\sum_{i=1}^{7} B_{i 3} \text { Fields }+\sum_{i=2}^{7} B_{i 4} \text { Fields } \times \text { Age }\right]
\end{aligned}
$$

We use a semilogarithmic form with a concave relationship between earnings and age to estimate returns by level of study. When we take into account the fields of study at the university level, we add the terms in brackets. The seven dichotomous variables of the fields of study modify the intercept, and interacting with the age variable, they modify the slope of the equation.

8 Private and public monetary retums

The regression results used in the study are presented in Tables A-1 to A-9 (Appendix A). In general they can be summarized as follows:

- Age earnings profiles are concave, with peaks reached in most cases by the age of 40-50;
- The $R^{2} \mathrm{~s}$ tend to be higher for secondary schooling than for lower (elementary) or higher (postsecondary) levels of schooling; and
- The $R^{2} s$ tend to be higher for men than for women in a given level of schooling.

We use both gross earnings (i.e., earnings before income taxes) and net earnings to calculate public and private rates of return. We thus assume that gross earnings measure the individual's contribution to society and net earnings represent what the individual keeps.

Since earnings include both wages, salaries, and net self-employment income, a small part of earmings represents the net returns to nonhuman capital used by the self-employed. It is a small amount because it is a part of selfemployment income, which itself represents a small proportion of earnings. The only way to exclude this kind of income, given the data available, is to omit individuals with self-employment income. This would lead to serious biases in the estimation of the returns to education in fields of study whose graduates often engage in self-employment. This is particularly true for holders of health degrees (e.g., M.D.), but also applies to holders of other degrees, such as engineering.

We estimate the earnings equations using 1986 census microdata to project the earnings profile over the working lives of individuals, assuming that it is possible to account for inflation (if any) in the tax system so as to leave real earnings unchanged. We also assume that there is no general increase in productivity through time. Such an increase would result in an upward drift in all eamings profiles. Taking into account either the imperfect correction for inflation by an indexed income tax system or a reasonable level of growth in productivity would not strongly alter our results (Vaillancour and Henriques 1986).

A more fundamental problem is that we are using single-year (crosssectional) results to represent lifetime employment income. This is both unavoidable and common practice in this kind of study, given the lack of longitudinal data in Canada and most other countries. Fortunately, 1985 was neither highly recessionary (as was 1982) or expansionary (as was 1984) and is thus reasonably representative of the 1980 s , with the unemployment rate at 10.5 per cent being almost equal to the five-year mean in 1983.87 of 10.4 per cent. ${ }^{3}$

Gross earnings are calculated by entering the appropriate ages in the equations and the field of study/age impacts, but only for significant coefficients ( $t>1.645$ ). To do this, both the starting and ending ages of the various ageearnings profiles must be specified. The starting ages were ascertained through a combination of analysis of the data and information on the usual length of schooling. ${ }^{4}$ The ending age was set at 64 , which assumes that all individuals retire on their 64 th birthday and do not work in their 65 th year.

The earnings at the time of the census of all individuals with the relevant level and type of schooling are calculated. Unfortunately, information on school attendance was not collected in the 1986 census. As a result, it is not feasible to separate individuals still attending school from those who are not. This means that the earnings of those with schooling above the elementary level underestimate the returns to regular employment for a given level of schooling, since the earnings of individuals studying for a higher level of schooling are taken into account in these calculations. While both sets of coefficients in a comparison such as that of the university and the secondary levels are affected, it is not cerlain that these effects cancel each other out. If the proportion of individuals with a given level of schooling that are studying for a higher-level degree decreases with an increase in that level of schooling, this could lead to an upward bias in the rate of retum as schooling increases.

One solution to this problem is to restrict the study to individuals who were employed full-ime ( 48 weeks or more) in 1985. By doing this, however, one would be neglecting the fact that the unemployment rate decreases with schooling, which is one of the determinants of the returns to schooling. This would bias downward all rates of return to schooling.

Net earnings are calculated by subtracting personal income taxes from gross earnings. Tax burdens were calculated for each gross eamings profile using a computerized, simplified version of the 1985 tax return. The following assumptions were made :

- All taxpayers claim the personal exemption. They also claim the employment expense deduction, the Canada/Quebec Pension Plan and unemployment insurance premium deductions, and a combined Registered Retirement Savings Plan/Registered Pension Plan deduction.
- Federal and Quebec income cax rates and specific provincial rates are used - (Ontario - 0.48 per cent; Alberta - 0.435 per cent; British Columbia 0.44 per cent). Unweighted means of relevant rates are used for the Atlantic region ( 0.5675 per cent) and Prairie region ( 0.5225 per cent). The Ontario rate is used for the calculation of the rate for Canada.
- The federal general tax reduction ( $\$ 100$ ) and surtax ( 2.5 per cent), the Quebec general tax reduction ( 3 per cent) and the Ontario, Alberta, and British Columbia tax reductions are taken into account.

## Costs of schooling

The public cost of schooling is the resources required by the economy to produce a given amount of schooling, and the private cost is the resources expended privately by the individual receiving that amount of schooling. In Canada, the public cost of a given amount of schooling is significantly higher than the private cost, because education is publicly subsidized. The share of private cost increases, however, with the level of schooling. The public and the private costs can be broken down into two major components: forgone earnings and out-of-pocket expenses. For public costs, gross earnings are used, while for private costs, net earnings are used. For out-of-pocket expenses, the student-related income of universities from public subsidies and tuition fees and the direct costs to students of books and supplies should be included to calculate public costs. Public subsidies should not be included in calculating private costs. Note that food and housing costs such as residence fees should not be included, since these costs are incurred by students and nonstudents alike. ${ }^{5}$

In this study, annual gross and net forgone earnings are calculated using the earnings equations found in Tables A-1 to A-9; the appropriate months of summer work was determined by the length of the academic year. Forgone earnings are estimated using the annual eamings for the appropriate lower level of schooling multiplied by the portion of the year worked. Data on annual out-of-pocket expenses are obtained for 1985-86 from a variety of sources. Most of these sources provide annual data for the 1980-90 period. A comparison of the data for 1985-86 with that for surrounding years indicates that 1985-86 is a normal year for the period.

No data were available on the expenses of books, supplies, etc., for the elementary, secondary, and college levels. Therefore, these expenses were assumed to equal to $\$ 100$ per year of elementary study, $\$ 200$ per year of secondary schooling, and $\$ 300$ per year of college-level study in all regions (1985 dollars). Data are available on the expenses of Canadian university students by province for the year 1983-84. There is no differentiation between expenses for undergraduate and graduate students or between those for students in different fields of study. Nonfee costs to students are presented in Table 3.

There are no tuition fees for elementary and secondary school students attending public schools in Canada. Private schools and colleges charge tuition fees, but these are not considered here. College fees vary according to
Table 3
Nonfee costs to students in four levels of study, Canada and regions, 1985-86'

## 12 Private and public monetary returns

the program (Stokes 1988: 125). Given our goal, we derived college fees from a ratio of college/university fees. Finally, university fees are averages of actual fees for 1985-86. Tuition fees are summarized in Table 4.

The data on public costs reported here are gathered by Statistics Canada. ${ }^{6}$ Some costs, such as depreciation property tax relief or forgone investment income, are not accounted for, or are not accounted for in a way that is strictly comparable between provinces.

The cost per student is broken down by province, but is not broken down into elementary and secondary costs. To calculate these costs, we used the following formula:

| Expenditure, <br> per elementary/ $/$ <br> secondary student | $=\left[\begin{array}{cc}\text { Expenditure } \\ \text { per elementary } \\ \text { student } & \times \frac{\text { Number of }}{\text { elementary students }}{ }^{\text {Number of elementary }} \\ \text { and secondary students }\end{array}\right]$ |
| ---: | :--- |
|  | $+\left[\begin{array}{cc}\text { Expenditure } & \text { Number of } \\ \text { per secondary } \times \frac{\text { secondary students }}{\text { Number of elementary }} \\ \text { student } & \text { and secondary students }\end{array}\right]$ |

and postulated the relationship between primary and secondary expenditure to be: primary cost $=0.75$ secondary cost. ${ }^{8}$ Public costs are summarized in Table 5.

The cost of community college/CEGEP studies was calculated with the following formula ${ }^{9}$ :

Expenditure on posisecondary (nonuniversity) education

$$
\text { Full - time students }+1 / 3 \text { (part - time students) }
$$

The cost per university student is available only as an aggregate, with all levels and fields combined. To break it down by level and field of study, the following cost ratios, derived using information on the cost by level and field of study in Ontario, ${ }^{10}$ are assumed to hold for all provinces:

- Bachelor's degree level: education, humanities, social sciences, commerce, mathematics and pure sciences - 1 (reference point); engineering - 2 ; health - 5;

2 College fees were calculated as follows: first, a community college/university lee ratio for 1983-84 for Canada as a whole and for the four regions |Atlantic, Quebec, Ontario. West (Prairies. Alberta. British Columbia)] for which Stokes (1988, 124-5) reports data was calculated. The data used by Stokes are taken from the 1984 Sunvey of Post Secondary Students carried out by Statistics Canada (1988, 103). The ratio for Canada is calculated using simple means of male and female tuition and required fees. These ratios are: Canada-0.38: Allantic - 0.35; Ouebec-0.24; Ontario-0.43; Prairies - 0.48; Alberta-0.48; British Columbia-0.48. Second. these ratios were applied to university fuition fees and yielded the college fution fees.
Table 4 (cont'd)
3 University fees were calculated as follows: Tuition Fees and Living Accommodation Costs at Canadian Universities, Statistics Canada (81-219), Table 1, 1985-86. Data to lines $25-26,28-41$, the Praines to lines 44, 47,50-53, 55, and British Columbia to lines 56,58 and 60 . In the Atlantic region, Cape Breton University, Kings College, Mont Saint Vincent, Nova Scotia Agricultural College, Nova Scotia College of Art and Design, Universite Sainte Anne and Saint Mary's Universiry were excluded. In Bonilace (Manitoba) and in Alberta, Camrose Lutheran College are excluded. Finally, in British Columbia, the Seminary of Christ the King and Trinity Western University are excluded. Fees for university students were calculated as the unweighted means of lees at major universities in each region. Fees for undergraduate education, commerce, engineering and science studies, and graduate (M.Sc.; Ph.D.) studies are taken directly from the table. Fees for humanities and social sciences are those for art degrees. Fees for health degrees are those for medicine. Canadian fees are an unweighted mean of provincial fees for the appropriate field of study.

The annual cost for a bachelor's degree in all lields is 1.5 times the cost of a bachelor's degree in education, commerce, social sciences, and humanities. The annual cost for a master's degree in all fields is the mean of the costs of both specific master's degrees.
Sounce Compiled by the author from various sources.

- Master's degree level: education, humanities, social sciences, commerce -2 ; mathematics and pure sciences, engineering, health -3 ; and
- Ph.D. level: all disciplines - 6 .

Using these cost ratios, enrollment information, ${ }^{11}$ and overall costs, ${ }^{12}$ and using a formula similar to the one used for elementary/secondary students (but with six terms instead of two), one can derive the costs per level/field of study.

For both forgone eamings and out-of-pocket expenses, annual costs are added up for the relevant number of years without present-value calculations. These aggregate costs are reported in Tables A-10 to A-15 (Appendix A). Elementary schooling is assigned a length of six years; incomplete high school a length of three years; high school a length of six years (three more); community college a length of three years (after high school); bachelor's degree a length of four years (after high school); master's degree a length of two years (after a bachelor's degree); health degree a length of six years (after high school); and Ph.D. a length of four years (after a master's degree). These lengths of time are assumed to be uniform across regions to facilitate comparisons.

Finally, the rates of return obtained from combining the earnings profiles of individuals living in a given province on 4 June, 1986 (the date of the census) with the costs of schooling in that province in 1985-86 are calculated. This implies not only that individuals completed their studies in the standard length of time, but also that they acquired their last two levels of schooling in the province in which they resided in 1986 (or in a province with similar costs). This can lead to mismeasurement of the rate of return if, for example, an individual moves from a low cost/low earnings to a high cost/ high earnings region, or vice versa, after completing school. The available mobility data does not allow us to control for this.

## Returns to schooling

In this part, we present results by levels of schooling for Canada as a whole. We then disaggregate these results by region for high-school graduates and holders of a bachelor's degree or by fields of study at the bachelor's degree level. The disaggregations were selected on the basis of both sample size and potential interest to the reader. Table 6 presents results for Canada as a whole. Private rates of return are higher than public rates of retum - even with a progressive income tax system - indicating the importance of public funding in this field. Rates of return for the high-school level are higher than postsecondary schooling, and there is a tendency for returns to schooling to decline
with the level of schooling - a result common in this type of study. Finally, it shows generally higher rates of return for postsecondary schooling for women than for men, presumably because of women's relative scarcity at that level of schooling in past years.

## Table 6

Summary of assumptions used in the study

| Assumptions |  | Comments/bias |
| :---: | :---: | :---: |
|  | Benefits measured by differences in earnings only | Fringe (employment), nonmarket production, child rearing, and consumption benefits are neglected. Large negative bias |
|  | All monetary costs are included | Idem |
|  | No correction for differences in ability | Uncertain impact |
|  | Individuals with no employment income are excluded, while those working part time by choice are included | Positive and negative bias: overall impact uncertain |
|  | Definition of earnings as wages + self-employment income | Lack of correction for returns to nonhuman capital used by the selfemployed - small positive bias |
|  | No correction for differential participation rate by level of schooling | Negative bias more important for women |
| 7) | No correction for differential mortality rate (same retirement age) by level of schooling | Small negative bias |
| 8) | Income tax fully indexed. Excess burden of taxes not taken into account | Small positive bias for private rates of return |
| 9) | No productivity growth | Negative bias |
| 10) | Individuals attending school included | Possible positive bias |
| 11) | Province of workresidence in 1986 assumed to be province of last two levels of study | Given Canadian migration and cost patterns, this could lead to a negative bias |

Since education is a provincial responsibility in Canada, it is appropriate to present rates of return on a provincial, or at least a regional basis. Table 7 reports the returns to completing high school rather than dropping out. These returns are presented instead of those associated with a comparison with elementary schooling because they are more relevant; given the laws on compulsory schooling.

Regional variations in rates of return reflect, in part, employment opportunities in the various sectors of the economy. Table 8 presents the rates of return to a bachelor's degree across Canada. Even with the presence of two outliers, British Columbia for men and the Atlantic provinces for women, these rates of return are less dispersed than rates of return to secondary education, reflecting the greater mobility of these individuals. The rates of return for males are similar to those reported by Vaillancourt and Henriques (1986a) for males, by region, in 1980 .

The regional dispersion of returns to university schooling is one relevant aspect of the level of schooling (Table 9). Another is the dispersion between fields of study of the returns to university schooling. Table 10 presents evidence for bachelor's degrees and healuh degrees (M.D., D.V.M., D.D.S.). Not surprisingly, the highest private rates of return are obtained by those holding health degrees while the lowest are obtained by holders of bachelor's degrees in the humanities. The relatively high returns to the social sciences compared to, say, pure sciences are due, in part, to the inclusion of lawyers in that group (due to the data). Gender differences in private rates of return for a given field, such as engineering, may reflect differences in the choice of subspeciality or aversion to risk.

## Conclusion

This paper has presented a set of rates of return to schooling in Canada for 1985. The results show the importance of completing a minimum level of schooling (high school), a decrease in rates of return to schooling with an increase in the level of schooling, some interregional variation in these rates of return, and important, but expected, differences among fields of study.

[^2]34 Private and public monetary returns

Table A-10
Public costs of completed secondary schooling compared with incomplete secondary schooling, Canada, 1985

|  | Direct costs | Forgone earnings |  | Total |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Majes | Females | Males | Females |
|  | (Doliars per student) |  |  |  |  |
| Region |  |  |  |  |  |
| Atlantic | 13,194 | 4,031 | 3,238 | 16,625 | 15,832 |
| Quebec | 19,707 | 3,957 | 3,386 | 23,064 | 22,493 |
| Ontario | 16,692 | 4,565 | 3,838 | 20,657 | 19,930 |
| Manitoba and |  |  |  |  |  |
| Saskatchewan | 15,846 | 5,367 | 3,994 | 20,613 | 19,240 |
| Alberta | 16,983 | 5,516 | 4,183 | 21,899 | 20,566 |
| British Columbia | 14,827 | 4,250 | 3,255 | 18,497 | 17,502 |
| Canada | 16,773 | 4,925 | 3,883 | 21,098 | 20,056 |

Note Tolal costs are the sum of direct costs and forgone earnings. Public direct costs are the sum of noniee cosis (Table 2) and public expenditures per student (Table 3) muluplied by the number of years of sludy. Private direct cosis are the sum of noniee cosis (Table 2) and fees (Table 3) muluplied by the number of years of siudy. Forgone earnings are compuled using the equations of Table A-1 to A-8 and the appropriate ages and lengths of schooling as follows:

| Level | Length of study <br> (years) | Age |
| :--- | :---: | :---: |
|  | 6 | $6-11$ |
| Elementary | 6 | $12-14$ (incompleie) |
| Secondary |  | 12.17 (complete) |
| College | 3 | $18-20$ |
| Bachelor's | 4 | $18-21$ |
| Master's | 2 | 22.23 |
| Ph.D. | 4 | $24-27$ |

[^5]
## Notes

1 Using the terms of the 1986 Census Public Use Sample Tape, this is the sum of the WAGESP and SELFIP variables.

2 In the case of the Allantic region, we could have regrouped only the Maritime provinces, or even only Nova Scotia and New Brunswick, but this would have been at the cost of excluding Newfoundland in both cases and P.E.I. in the second.

3 Canadian Economic Observer, Historical Statistical Supplement, 1989/ 90, Statistics Canada (11-210), Table 1.3, p. 7 for real GDP growth rates and Table 2.6, p. 34 for unemployment rates.

4 The following starting ages are used: elementary completed: 12 ; secondary incomplete: 15 ; secondary completed: 18 ; college: 21 ; university, bachelor's degree: 22 ; university, health degree: 24 ; university, master's degree: 24 ; university, Ph.D. degree: 28 . (The term "college" encompasses community colleges and CEGEP.)

5 The differential - positive or negative - between subsistence costs for a student and a nonstudent, should be included, but is not because the data are not available.

6 Financial Statistics of Education 1985-1986, Statistics Canada (81-208), Table 12, Item E (expenditures per student), 1986 entry. Expenses for the Atlantic and Prairies region are a weighted sum of these amounts; the weight is school enrollment (see note 16).

7 Elementary-Secondary School Enrollment 1985-86, Statistics Canada (81210), Table 5, Subwtals grades 1-6 and special (primary) and grades 713 and special (secondary).

8 This is the ratio calculated for Ontario for 1985 (Education Statistics Ontario 1987 Table 1.35 p. 21). This is the only province for which we found this information. Constantatos and West (1991) report that the ratio of secondary to primary costs is 1.3 , according to "consultation with Canadian education authorities" (p.8). This ratio is 0.77 in our terms.

9 Education in Canada 1986-1987, Statistics Canada (81-229). Data on expenditures are from Table 42. Where provincial data were missing for 1985-86, they were computed by multiplying provincial data for $1984-$ 85 by the change from 1984-85 to 1985-86 in figures for Canada. Data on enrollment are from Table 8 (total, 1985-86). The ratio $1 / 3$ is used to recognize the fact that part-time students are less costly than full-time students.

40 Private and public monetary returns
10 As represented by Basic Income Units (B.I.U.). See Stager (1989) for more on this. This appears to be the only source on relative costs by level/ field of university studies available for Canada.

11 Universities Enrollment and Degrees 1985, Statistics Canada (81-204). Data for bachelor's degrees are from Table 7, master's degrees from Table 9, and Ph.D.s from Table 10. Part-time enrollment is converted to full-time equivalents by multiplying it by $1 / 3$. Enrollment in bachelor'slevel studies in education, the humanities, commerce, social sciences, and mathematical and natural sciences is given by the sum of lines 2,3 , $4,5,15$ and 29 minus 35 ; enrollment in engineering is given by the sum of lines 38 and 55 ; and enrollment in health is given by the sum of lines 48 and 35 from Table 7. Enrollment in education, the humanities, commerce, and social sciences at the master's level is given by the sum of lines 2, 3, 4, 5 and 15 from Table 9, while enrollment in mathematical and pure sciences, engineering, and health at the master's level is given by subtracting the previous total from line 1 of that table.

12 Total costs are from Education in Canada 1986-1987, Statistics Canada (81-229), Table 42. Missing data for $1985-86$ were calculated as in the case of community colleges.
