A paper prepared for the

## Economic Council of Canada

Un document préparé pour le Conseil économique du Canada

The Economic Council of Canada was established in 1963 by Act of Parliament. The Council is a crown corporation consisting of a Chairman, two Directors and not more than twenty-five Members appointed by the Governor in Council.

The Council is an independent advisory body with broad terms of reference to study, advise and report on a very wide range of matters relating to Canada's economic development. The Council is empowered to conduct studies and inquiries on its own initiative, or if directed to do so by the Minister, and to report on these activities. The Council is required to publish annually a review of medium- and long-term economic prospects and problems. In addition it may publish such other studies and reports as it sees fit.

The Chairman is the Chief Executive Officer of the Council and has supervision over and direction of the work and staff of the Council. The expenses of the Council are paid out of money appropriated by Parliament for the purpose.

The Council as a corporate body bears final responsibility for the Annual Review, and for certain other reports which are clearly designated as Council Reports. The Council also publishes Research Studies, Discussion Papers and Conference Proceedings which are clearly attributed to individual authors rather than the Council as a whole. While the Council establishes general policy regarding such studies, it is the Chairman of the Council who bears final responsibility for the decision to publish authored research studies, discussion papers and conference proceedings under the imprint of the Council. The Chairman, in reaching a judgment on the competence and relevance of each author-attributed study or paper, is advised by the two Directors. In addition, for authored Research Studies the Chairman and the two Directors weigh the views of expert outside readers who report in confidence on the quality of the work. Publication of an author-attributed study or paper signifies that it is deemed a competent treatment worthy of public consideration, but does not imply endorsement of conclusions or recommendations by either the Chairman or Council members.

Établi en 1963 par une Loi du Parlement, le Conseil économique du Canada est une corporation de la Couronne composée d'un président, de deux directeurs et d'au plus vingt-cinq autres membres, qui sont nommés par le gouverneur en conseil.

Le Conseil est un organisme consultatif indépendant dont le mandat lui enjoint de faire des études, donner des avis et dresser des rapports concernant une grande variété de questions rattachées au développement économique du Canada. Le Conseil est autorisé à entreprendre des études et des enquêtes, de sa propre initiative ou à la demande du Ministre, et à faire rapport de ses activités. Chaque année, il doit préparer et faire publier un exposé sur les perspectives et les problèmes économiques à long et à moyen termes. Il peut aussi faire publier les études et les rapports dont la publication lui semble opportune.

Le président est le directeur général du Conseil; il en surveille les travaux et en dirige le personnel. Les montants requis pour acquitter les dépenses du Conseil sont prélevés sur les crédits que le Parlement vote à cette fin.

En tant que personne morale, le Conseil assume l'entière responsabilité des Exposés annuels, ainsi que de certains autres rapports qui sont clairement désignés comme étant des Rapports du Conseil. Figurent également au nombre des publications du Conseil, les Études, Documents et Comptes rendus de colloques, qui sont explicitement attribués à des auteurs particuliers plutôt qu'au Conseil lui-même. Celui-ci établit une politique générale touchant ces textes, mais c'est au président qu'il incombe de prendre la décision finale de faire publier, sous les auspices du Conseil économique du Canada, les ouvrages à nom d'auteur tels que les études, documents et rapports de colloques. Pour se prononcer sur la qualité, l'exactitude et l'objectivité d'une étude ou d'un document attribué à son auteur, le président est conseillé par les deux directeurs. De plus, dans le cas des études à nom d'auteur, le président et les deux directeurs sollicitent l'avis de lecteurs extérieurs spécialisés, qui font un rapport confidentiel sur la qualité de ces ouvrages. Le fait de publier une étude ou un document à nom d'auteur ne signifie pas que le président ou les membres du Conseil souscrivent aux conclusions ou recommandations contenues dans l'ouvrage, mais plutôt que l'analyse est jugée d'une qualité suffisante pour être portée à l'attention du public.

DISCUSSION PAPER NO. 204

# THE EFFECT OF INCOME TAX INCENTIVES ON RETIREMENT SAVINGS: SOME CANADIAN EVIDENCE

by

Michael Daly and Peter Wrage\*

\*The authors wish to thank, without implicating, Richard Arnott, Robin Boadway and an anonymous referee for their helpful comments and suggestions on an earlier draft.

The findings of this Discussion Paper are the personal responsibility of the authors and, as such, have not been endorsed by Members of the Economic Council of Canada.

Discussion Papers are working documents made available by the Economic Council of Canada, in limited number and in the language of preparation, to interested individuals for the benefit of their professional comments.

#### Résumé

La retraite est l'une des principales raisons d'épargner, et cette épargne est l'une des plus considérables de notre économie. En guise d'encouragement, le régime fiscal canadien prévoit d'importants allégements de l'impôt sur le revenu personnel dans le cas de l'épargne en vue de la retraite (au moyen des régimes de pension des employeurs et des régimes enregistrés d'épargne-retraite) ainsi que du revenu qui en découle. Dans le présent document, les auteurs cherchent à savoir dans quelle mesure les stimulants fiscaux actuels -- notamment l'exemption pour raison d'âge et la déduction aux fins de l'impôt, des cotisations aux régimes de pension et aux régimes enregistrés d'épargne-retraite -- encouragent vraiment l'épargne en vue de la retraite, et jusqu'à quel point ces privilèges fiscaux sont équitables.

#### Abstract

reason for and source of savings in the economy. By way of encouragement, Canada's personal income tax system accords substantial tax concessions to retirement saving (via employer-sponsored pension schemes and Registered Retirement Savings Plans) and income derived therefrom. This paper examines the extent to which the existing tax incentives, namely, the old age personal exemption and the tax-deductibility of pension plan and RRSP contributions, do, in fact, encourage retirement saving and whether this preferential tax treatment is equitable.

#### I. Introduction

In Canada, social policy aimed at providing adequate retirement incomes is a mixture of public programs, such as Old Age Security, the Guaranteed Income Supplement and the Canada and Quebec Pension Plans, and private schemes that are encouraged by substantial tax concessions. It is therefore important to understand how government retirement income programs together with the various tax incentives affect private retirement savings. Private saving for retirement purposes now constitutes a major component of total savings, and in the 1972-76 period was equivalent to 18 percent of gross saving. Hence, any changes in private retirement savings resulting from public pension programs and tax concessions may have important implications for economic growth and stability.

In this paper, we will focus our attention on the main tax incentives pertaining to retirement savings and income derived therefrom, and examine the extent to which they do in fact encourage such saving. We will also argue that the existing tax incentives should be replaced by something more equitable.

Section II describes the various tax concessions and what may be regarded as the conventional wisdom concerning their impact on private retirement saving. A theoretical model incorporating these tax concessions is developed in Section III together with the

comparative static analysis. Section IV links the theoretical analysis to the empirical estimation procedure followed by Section V which summarizes the empirical results. Finally, Section VI discusses these results and their policy implications.

#### II. The Existing System of Tax Incentives to Retirement Saving

As mentioned earlier, private programs now play an important role in retirement saving. In 1977, over four million employees or 40 percent of the Canadian labour force were covered by approximately 15,000 employer-sponsored pension plans with total contributions (employer and employee) amounting to \$6.2 billion. Related to, but separate from these institutionalized schemes are the Registered Retirement Savings Plans (RRSPs) which serve as a vehicle for personal retirement saving either exclusively or in conjunction with employer-sponsored schemes<sup>1</sup>. RRSPs have experienced a phenomenal rate of growth in recent years as an increasing number of individuals have taken advantage of the tax saving associated with such plans. In 1977, approximately 1.3 million persons contributed a record \$2,369 million (compared to \$320 million by 348,000 persons in 1971), thus exceeding the total of employee contributions paid into all employer-sponsored plans.

The Individual Retirement Account (I.R.A.) in the United States is based on the RRSP program in Canada. Similar programs also exist in many of the European countries. See "Individual Retirement Account", John H. Hall, National Tax Journal, Vol. 27, No. 3 September 1974, pp.459-65.

The attractiveness of employer-sponsored plans and especially RRSPs is in large part due to the fact that Canada's Income Tax Act provides that contributions to such schemes are, within certain prescribed limits, deductible from gross income in determining taxable income<sup>2</sup>. The individual contributor therefore gains in two ways. First and foremost, by contributing to an employer-sponsored pension scheme or an RRSP, he defers his tax liability until retirement. In most cases, an individual's marginal rate of income tax rate will be lower on retirement than when contributions were paid in; this is largely due to the fact an individual's employment earnings, if any, are much lower. In addition, as a result of the old age personal exemption for persons aged 65-and-over, amounting to \$1,660 in 1979, together with the \$1,000 pension income deduction, any annuity income derived from a registered pension plan is taxed at a rate much lower than pre-retirement income. Second, a contributor

As of 1977, an employee is allowed to deduct from his taxable income any amount up to \$3,500 in any year withheld from his wages or salary and paid to an employer-sponsored pension plan in respect of his services in that year. Individuals who do not participate in an employer-sponsored pension plan can contribute as much as 20 per cent of their annual earned income, up to \$5,500, to an RRSP and deduct these contributions from their gross income in determining taxable income. Participants in an employer-sponsored pension plan who contribute less than 20 percent of their annual earned income, up to \$3,500, may contribute the difference to an RRSP.

earns the gross rate of interest on such retirement saving as long as the interest earned is not received as income<sup>3</sup>.

According to what may be described as the "conventional wisdom", the foregoing tax treatment of contributions and earnings of employer-sponsored pension plans and RRSPs "provide a strong incentive of individuals to increase their overall level of saving" (Johnson, 1977). Furthermore, it has been suggested by Turner (1977) that the preferential tax treatment of the elderly through the old age exemption, by lowering the marginal tax rate paid by older taxpayers, would also have a positive effect on retirement saving.

In what follows, we will re-examine the theoretical foundations for this "conventional wisdom" and demonstrate that neither conclusion is justifiable on theoretical grounds. Indeed, from our theoretical model alone, it becomes clear that the effect on retirement saving of both the tax deductibility of contributions to employer-sponsored pension plans and RRSPs and the old age exemption is necessarily ambigous. Moreover, under certain assumptions we will show that the old age exemption has an adverse effect on retirement saving, a conclusion which is supported by our empirical results.

<sup>3</sup> It should also be mentioned that interest on money borrowed to pay RRSP premiums is deductible from gross income in determining taxable income.

By contrast, although the effect of the tax rate is theoretically ambiguous, our empirical findings show that an increase in the tax rate encourages retirement saving. Because of the tax deductibility of contributions to employer-sponsored pension plans and RRSPs, the higher the tax rate on pre- as opposed to post-retirement income, the more attactive it is for a person to contribute to tax-deductible retirement savings schemes in order to defer his or her tax liability until retirement. This increases the tax saving associated with such contributions.

#### III. A Theoretical Model

The life-cycle model provides a particularly useful framework for analysing the effects of tax incentives on individual saving behaviour. According to this model, an individual saves during his working life in order to provide himself with an adequate level of consumption during retirement. As a simplifying assumption, we will ignore the bequest motive for saving.

It will be convenient to distinguish between two periods in the life-cycle; period 1, corresponding to an individual's normal working life which we will assume to be from the age of 15 up to the age of 65, and period 2, commencing on an individual's 65th birthday. Upon the attainment of that age, not only does the old age exemption

become effective, but almost everybody becomes a recipient of the Old Age Security pension. The earnings-related CPP/QPP also becomes payable at age 65. We define  $C_1$ , as the annual current consumption of some composite commodity during an individual's working life and  $C_2$  as the annual consumption of the same composite commodity during retirement.

We will make the following behavioural assumptions:

(Al) The typical individual has a well-defined utility function
U, such that

$$U = U (C_1, C_2)$$

The utility function is everywhere twice differentiable so that,

$$U_{ij} = U_{ji}$$
 where  $i \neq j$  and  $i, j = 1, 2$ 

$$U_{i} = \frac{\partial U}{\partial C_{i}} = 0$$
 where  $i = 1, 2$ 

$$U_{ii} = \frac{\partial^{2}U}{\partial C_{i}} = 0$$

(A2) Retirement saving R, only takes place in period 1 and is deductible from taxable income  $Y_1$ , in the same period.<sup>4</sup> We

While pension savings in the form of RRSPs is the result of an individual's own decision, this is not generally the case with employer-sponsored pension plan saving. The latter is jointly determined by the employer and employee or his representatives via collective bargaining, so that from the individual's point of view, it may be regarded as a form of forced saving. Nevertheless, we will assume that total retirement savings (of employer-sponsored pension savings and RRSPs) is determined by individual preferences.

will assume that there is no effective limit on the tax deductibility of such retirement saving except that  $Y_1 - R \stackrel{>}{=} 0.5$ 

- (A3) All such retirement saving, R, is received as personal income in period 2 having earned a real rate of interest, r.
- (A4) The marginal tax rate on personal income in period 1, t<sub>1</sub>, is greater than that in period 2, t<sub>2</sub>. Initially, we will assume that t<sub>1</sub> and t<sub>2</sub> are determined exogenously with regard to the model which implies that, for any small change in our dependent variable R, the individual does not change tax bracket. (In fact, as our empirical results will show, this turns out to be a reasonable assumption.)
- (A5) In period 2 the individual becomes eligible for public pension benefits, B.
- (A6) E denotes age-specific exemptions which are effective in period 2.

By definition  $E \leq R (1 + r) + Y_2 + B$ ,

where  $Y_2$  denotes other income in the form of earnings received during the second period.

<sup>&</sup>lt;sup>5</sup> Individual preferences and/or capital market imperfections are such that according to Revenue Canada Taxation data, the vast majority of contributors to employer-sponsored pension plans and RRSPs do not put aside the full allowable amount. Indeed contributions are well below the maximum.

The consumer is assumed to choose  $C_1$  and  $C_2$  so as to maximize his utility,  $U = U(C_1, C_2)$  subject to the following constraints:

(i) 
$$C_1 = (1-t_1) (Y_1 - R)$$

(ii) 
$$C_2 = (1-t_2) (Y_2+R(1+r)+B-E)+E$$

Substituting for  $C_1$  and  $C_2$  into U is equivalent to choosing R so as to maximize  $U_\bullet$ 

$$U = U[(1-t_1)(Y_1 - R) ; (1-t_2)(Y_2+R(1+r)+B-E)+E]$$

Without loss of generality, for our theoretical analysis we will assume that r,  $Y_2$  and B take on the value zero.

(1) 
$$U = U [(1-t_1) (Y_1 - R); (1-t_2) (R - E) + E]$$

The first-order condition for U to be a maximum is

(2) 
$$\partial U/\partial R = -(1-t_1) U_1 + (1-t_2) U_2 = 0$$

The second-order condition is 6

(3) 
$$\delta^2 U / \delta R^2 = (1-t_1)^2 U_{11} + (1-t_2)^2 U_{22} - 2U_{12} (1-t_1) (1-t_2) \angle 0$$

If we differentiate the <u>first-order</u> condition with respect to  $t_1$ ,  $t_2$ ,  $Y_1$ , E and R, we derive the following comparative static results:

<sup>&</sup>lt;sup>6</sup> For convenience, we will define  $3^2U/3R^2 = D \angle 0$ 

(4) 
$$\frac{R}{2t_1} = -U_1 + (1-t_2) (Y_1 - R) U_{21} - (1-t_1) (Y_1 - R) U_{11}$$

(5) 
$$\frac{R}{2t_2} = U_2 - (1-t_1) (R-E) U_{12} + (1-t_2) (R-E) U_{22}$$

(6) 
$$\frac{R}{\frac{R}{Y_1}} = \frac{-(1-t_1)(1-t_2)U_{21} + (1-t_1)^2U_{11}}{D}$$

(7) 
$$\frac{R}{E} = \frac{(1-t_1) t_2 U_{12} - (1-t_2) t_2 U_{22}}{D}$$

Substituting for  $\frac{\partial R}{\partial Y_1}$  and  $\frac{\partial R}{\partial E}$  into Equations (4) and (5), respectively

we derive the following Slutsky-type equations,

(8) 
$$\frac{\partial R}{\partial t_1} = \frac{-U_1}{D} - \frac{Y_1 - R}{1 - t_1} \cdot \frac{\partial R}{\partial Y_1}$$
 D<0

where  $-\frac{U}{D}l$  may be termed the pure  $tax^{1}$  effect of  $t_{1}$  and

 $-\frac{Y_1-R}{1-t_1} \cdot \frac{\partial R}{\partial Y_1}$  the income effect. For an increase in t<sub>1</sub>, the pure tax

effect increases R while the income effect is indeterminate.

(9) 
$$\frac{\partial R}{\partial t_2} = \frac{U_2}{D} - \frac{(R - E)}{c_2} \frac{\partial R}{\partial \xi}$$

where  $\frac{U}{D}$  may be termed the <u>pure tax effect</u> of t<sub>2</sub> and  $-\left(\frac{R-E}{t_2}\right) \cdot \frac{\partial}{\partial E}$  the <u>exemption effect</u>. For an increase in t<sub>2</sub>, the <u>pure tax effect decreases</u> R while the <u>exemption effect is indeterminate</u>.

<sup>7</sup> The pure tax effects are analogous to the pure substitution effects.

Due to the indeterminacy of the income and exemption effects, we cannot say how retirement savings is affected by  $t_1$ ,  $t_2$ ,  $Y_1$  and E without some further assumptions.

It does not seem unreasonable to assume that both  $C_1$  and  $C_2$  are normal goods with respect to an individual's lifetime income. Hence,  $\frac{\partial R}{\partial Y_1} \ge 0$  and  $\frac{\partial R}{\partial E} \le 0.8$  This implies that  $Y_1$  has a positive effect on retirement saving while the exemption has a negative effect. However, without further restrictions on the individual's utility function, one cannot determine the effects of  $t_1$  and  $t_2$  on such savings.

An increase in exemptions E is equivalent to an increase in after tax income of  $t_2$ E for an individual with taxable income in period 2. If both  $C_1$  and  $C_2$  are normal goods, then some of this increase in after tax income will be spent on  $C_1$  and hence result in a fall in R.

#### IV. An Additional Complication

Before attempting to estimate empirically the effects of changes in  $t_1$ ,  $t_2$ ,  $Y_1$  and E on retirement saving, an additional complication needs to be introduced, namely, the fact that the income tax system is progressive rather than proportional. This is of particular importance with regard to changes in  $Y_1$  and E. In the case of the latter, it is usually argued that an increase in old age exemptions will encourage retirement saving since such exemptions lower the marginal tax rate of retired individuals. This would appear to contradict our earlier conclusion that, if  $C_1$  and  $C_2$  are normal goods, then  $\frac{R_2}{\lambda_L}$ 0. In what follows, we will show that there is, in

fact, no contradiction but rather a failure to distinguish two closely connected effects.

In practice, under a progressive income tax system, the marginal tax rate is not altogether independent of taxable income as assumed in our model (A4). It may be the case that for small change in E and R the majority of taxpayers do not change tax bracket. However, in general as an individual's taxable income increases he tends to face higher marginal tax rates. The marginal tax rate is thus to some extent endogenously determined. Indeed, we may define our tax function as follows:

(13) 
$$t_1 = t_1 (Y_1-R)$$
 and  $t_2 = t_2(R-E)$ 
where  $\frac{\partial t_1}{\partial Y_1}, \frac{\partial t_2}{\partial R} \geq 0$  and  $\frac{\partial t_1}{\partial R}, \frac{\partial t_2}{\partial E} \leq 0$ 

Consequently, when we estimate the effect of a change in old age exemptions on retirement saving, we are in effect estimating the following:

$$\frac{dR}{dE} = \frac{\partial R}{\partial E} + \frac{\partial R}{\partial t_2} \cdot \frac{\partial t_2}{\partial E}$$

that is, we are differentiating R with respect to E when  $t_2$  is allowed to change. From our assumption that  $C_1$  and  $C_2$  are normal goods, and our progressive income tax function, we know that

$$\frac{\partial R}{\partial E} \neq 0$$
,  $\frac{\partial t}{\partial E} \neq 0$ . If  $\frac{\partial R}{\partial t_2} = 0$  then it follows that  $\frac{dR}{dE} = 0$ .

However, if  $\frac{\partial R}{\partial t_2} = 0$  then the sign of  $\frac{dR}{dE}$  becomes ambiguous.

Similar identification problems exist with respect to changes in Y1. What we estimate is  $\frac{dR}{dY_1}$ 

We are ignoring any second round effects whereby an induced change in R will in turn have a further impact on t<sub>2</sub>.

where 10

$$\frac{dR}{dY_1} = \frac{\partial R}{\partial Y_1} + \frac{\partial R}{\partial t_1} \cdot \frac{\partial t_1}{\partial Y_1}$$

and

$$\frac{\partial R}{\partial Y_1} \to 0$$
 and  $\frac{|t_1|}{\partial Y_1} \to 0$  follow from our assumptions.

Since

 $\frac{\partial R}{\partial t_i}$  may be positive or negative, the sign of  $\frac{dR}{dY_i}$  is

ambiguous.

As is so often the case, a theoretical analysis can illuminate the ways in which public policy affects individual behaviour, but it cannot yield an estimate of the magnitude of the effect nor even an unambiguous conclusion about the signs. For this, we must turn to an empirical investigation.

#### V. Empirical Estimation

In order to determine empirically the effect of tax incentives on retirement savings, it is necessary to specify the retirement savings function. Given a typical individuals' utility, function U, where

$$U = U [(1-t_1) (Y_1-R); (1-t_2) (Y_2+R (1+r) + B - E) + E]$$

<sup>10</sup> Again we are ignoring any second round effects whereby an induced change in R will have a further impact on t<sub>1</sub>.

we will assume that, for all positive values of the exogenous parameters r,  $t_1$ ,  $t_2$ ,  $Y_1$ ,  $Y_2$ , B and E, a unique maximum is attained at which  $R^{\, \triangle} \, 0$ . Then the solution to the maximization problem in Section III gives the choice variable R as a function of these parameters. Hence, a general retirement savings function is given by,

(14) 
$$R = R (Y_1, \frac{1}{1-t_1}; \frac{1}{(1-t_2)(1+r)}, \frac{t_2E}{(1-t_2)(1+r)}, \frac{Y_2}{1+r}, \frac{B}{1+r}).$$

Since retirement savings has two main components, RRSPs and employer-sponsored plans (denoted by  $R_1$  and  $R_2$  respectively), one of which may be a partial substitute for the other, two corresponding retirement equations were estimated. While one would not expect RRSP contributions to have much, if any, effect on employer-sponsored plan contributions because individuals have little discretion with regard to the latter, the converse is unlikely to be the case. RRSP saving  $(R_1)$  is likely to be affected by  $R_2$  especially for those individuals who contribute to both types of plans. Consequently, employer-sponsored pension savings  $(R_2)$  was included in the RRSP  $(R_1)$  equation in order to estimate the degree of substitutability between these two forms of retirement saving.

Retirement savings decisions in period 1 may be influenced not only by tax incentives but also by expected future benefits in period 2 from public pension programs. Following Feldstein (1974) and Munnell (1974), one can define such a variable as a measure of the

perceived increase in permanent income, i.e. public pension plan wealth  $^{11}$ . We will distinguish between OAS wealth a, and CPP/QPP wealth s, both of which are included as a proxies for B. (It should be pointed out that the third argument of equation (14) is omitted as a variable in the following empirical specifications on the grounds that it would be collinear with the fourth argument since both involve the term  $1/1-t_2$ .)

To eliminate the effects of population and price level changes, all monetary variables in the retirement savings equation were estimated in real per capita terms. The equations were estimated with all variables in the log form, that is,

(16) 
$$\log R_1 = b_0 + b_1 \log y_1 + b_2 \log y_2 + b_3 \log m_1 + b_4 \log m_2 + b_5 \log e + b_6 \log r + b_7 \log a + b_8 \log s + b_9 \log p$$
 and

(17) 
$$\log R_2 = c_0 + c_1 \log y_1 + c_2 \log y_2 + c_3 \log m_1$$
  
+  $c_4 \log m_2 + c_5 \log e + c_6 \log r + c_7 \log a + c_8 \log s$ 

where p refers employer-sponsored pension plan wealth, e exemptions, and r is the yield on trust certificates of five years or more.

This wealth measure is an estimate of the present value of the expected future benefits taking into consideration coverage, life expectancy, age, benefit rates and the real per capita growth of income. Of course, this wealth is not tangible wealth, but only an implicit promise to pay. Nevertheless, even if no tangible assets correspond to this wealth, it is still perfectly rational for households to regard such expected future benefits as part of their personal wealth. The estimates of these wealth variables were provided by P.P. Boyle and J. Murray from their paper entitled, "Social Security Wealth and Private Savings in Canada", University of British Columbia, Working Paper #574, Mimeo, April 1978.

While we assumed in our theoretical model that changes in E and R were not large enough to affect the tax rates  $t_1$  and  $t_2$ , in reality these tax rates may be partially affected by E and R via changes in taxable income. Consequently the following tax rate equations were estimated, providing  $m_1$  and  $m_2$  as instrumental variables in the retirement savings equations.

(15a) 
$$m_1 = f(Z_1)$$

(15b) 
$$m_2 = g(Z_2)$$

where m is the average tax rate,  $f^1$ ,  $g^1 o 0$  and  $Z_1 = Y_1 - R$ ,  $Z_2 = Y_2 + R(1+r) + B - E$ , i.e. both  $Z_1$  and  $Z_2$  denote taxable income in periods 1 and 2 respectively, while  $Y_2$  denotes other income in the form of earnings and/or income from other assets.

The corresponding personal income tax rate equations are estimated linearly with all variables in nominal, per capita terms.

(18) 
$$m_1 = f_0 + f_1 Y_1 + f_2 X_1 + f_3 K_1 + f_4 D_1 + f_5 T$$
 and

(19) 
$$m_2 = g_0 + g_1 Y_2 + g_2 X_2 + g_3 D_2 + g_4 E + g_5 T$$

where Y, X and D are assessed personal income, personal exemptions and personal deductions in periods 1 and 2 respectively  $^{12}$ . To examine the

<sup>12</sup> For a definition of all variables used in all the estimations and their source, see Appendix A

direct effect of R on the tax rate, total pension plan contributions  $K_1$ , were included separately in equation (18). Similarly, to examine the direct effect of old age exemptions E, on the tax rate, it was included separately in equation (19). T is a time trend reflecting changing personal income taxation rates.

All equations are estimated, using taxation data provided by Revenue Canada, for the period 1964 to 1976. The data were disaggregated by sex and a sex dummy variable included in all equations because income patterns differ between males and females. The equations were estimated by the instrumental variable technique with the log transformation of the estimated tax rates m<sub>1</sub> and m<sub>2</sub> as the instrumental variables. Estimates of the direct effects of tax incentive on retirement saving are presented in Table 1. Estimates of the effects of the incentives on the tax rates are presented in Table 2.

As expected, changes in the pre- and post-retirement tax rates, induced by existing tax incentives, have a significant effect on retirement saving  $(3R/3m_1^2)$ ,  $(R/3m_2^2)$ . An increase in  $m_1$  relative to  $m_2$  increases retirement saving. If the partially offsetting effect of  $m_2$  is taken into consideration,  $R_1$  and  $R_2$  increase by about 4 percent for a 1 percent change in the average tax

rates (Table 1)<sup>13</sup>. It suggests that incentives affecting the relative tax rates are major potential policy levers for changing retirement saving behaviour.

The tax rate effect on retirement saving is to some extent offset by the effect of the old age exemption which has a significant negative impact on retirement saving  $(\partial R/\partial e \leftarrow 0)$ . While this result contradicts Turner's conclusion for the United States and the widely held view that such exemptions encourage retirement saving, our theory showed that R/020 if consumption in both periods is a normal good. Furthermore, any increase in exemptions appears to reduce retirement saving by less than a proportional amount. Since one would expect the rise in income to E resulting from an increase in E to increase consumption in both period, retirement saving would be reduced in period 1. Our results in Table 2 also support the hypothesis that the direct effect of the old age exemption on retirement saving & R/& E dominates the tax effect induced by a change in this exemption i.e. R >t2).14 Nevertheless, Turner's results are not necessarily dt2 dE Nevertheless, Turner's results are not necessarily incorrect if the positive tax-induced effect dominates the direct exemption effect in the United States.

 $\frac{14}{E} = 0.919$  and  $\frac{dR}{dt_2} = (8.135) \times (0.865 \times 10^{-4}) = .0007$ .

Individuals make retirement saving decisions based on both pre-retirement and their expected post-retirement tax rates and real incomes i.e. m<sub>1</sub>, y<sub>1</sub>, m<sub>2</sub> and y<sub>2</sub>. The latter are assumed to equal the current, observed post-retirement tax rate and income of individuals 65 years and over. Similarly, the old age exemption effect in real terms is based on an individual's expected exemption assumed to equal the observed exemption applicable to individuals aged 65 years and over.

The level of real, per capita before-tax income also has a significant effect on retirement saving behaviour  $(\partial R/\partial Y_1 - 0)$ . In the case of RRSPs, the elasticity is greater than unity (5.9) implying that saving via RRSPs increases as a proportion of pre-retirement income,  $y_1$ , as the latter increases. In other words, RRSPs are a luxury good. This confirms Schoeplein's [8] findings that it is primarily middle and especially upper income groups who save for retirement and supports Holland's [6] assertion that the "demand for pensions ...is elastic with respect to income". On the other hand, this is not the case for employer-sponsored pension saving  $(R_2)$ . An aggregate income elasticity of approximate unity over time is hardly surprising given the institutional fact that pension contributions are usually proportional to income.

Although the coefficients of the social security wealth variables have a negative sign, only CPP/QPP has any significant effect on  $R_2$ . This may be explained by the fact that most employer-sponsored pension plan members belong to plans which are integrated with the CPP/QPP. 15

The results from the tax rate equations in Table 2 are consistent with the expected signs on the coefficients. Total pension

<sup>15 &</sup>quot;Integrated Plans" are defined as those that provide a lower level of contributions and/or benefits on all or part of the year's Maximum Pensionable Earnings under the CPP/QPP or that provide for pensions to be reduced by all or part of the C/QPP benefit.

<sup>1</sup> Excludes old age exemptions

<sup>&</sup>lt;sup>2</sup> Excludes Pension Plan Contributions

plan contributions, while having the correct sign, have no significant effects on the tax rate in period 1. It suggests that taxpayers do not change tax brackets as a result of such contribution (A4). However, changes in income and the old age exemptions do affect the tax rates, justifying the assumption that tax rates are partially endogenously determined. Consequently, an instrumental variable approach was appropriate under the circumstances.

Finally, it is not altogether surprising that our empirical findings indicate that tax incentives and other variables have an overall stronger effect on RRSPs than on employer-sponsored plans i.e. for all those variables which are statistically significant in both regressions, the magnitudes of their coefficients in the RRSP equation  $(R_1)$  exceed those of the employer-sponsored pension saving equation  $(R_2)$ . Since RRSPs are more "personalized" than pension savings through employer-sponsored plans i.e. provide greater freedom for individual choice, one could expect RRSPs to be more sensitive to changes in these variables.

#### VI. Conclusions and Policy Implications

#### (1) The Case for Abolition of the Old Age Exemption

Our theoretical and empirical findings cast doubt upon the efficacy of the old age exemption in encouraging retirement saving.

Evidence from time series data indicates that, contrary to the

conventional wisdom, this exemption has had an adverse, albeit minor,

effect on retirement saving. Thus, if it is an objective of public

policy to provide private retirement saving, one should reconsider the

use of the old age exemption for this purpose.

Insofar as the elderly face special living expenses, an additional exemption might be appropriate. While this may have been true in 1948 when the old age exemption was introduced, there is little evidence to suggest that it is the case at present. Even as early as 1966, the Carter Commission on Taxation concluded that no special exemption for the elderly was warranted. Since that time universal medical care has been introduced to provide basic security against health-induced financial problems for all Canadians.

When one also considers that, in many provinces, senior citizens are either exempt from health insurance premiums (or else entitled to rebates depending upon income) and also receive other ancillary benefits at little or no cost to themselves, it becomes increasingly doubtful whether the elderly require more income for subsistence than do the young. On the contrary, since the elderly incur less, if any, work-related expenses and have less need to save, it would appear that preferential treatment should be granted to the young rather than the old, implying that the old age exemption should be abolished on horizontal equity grounds.

Another view is that people with inadequate ability to pay should be exempted from paying taxes. Yet, to accomplish this does not require the granting of a similar exemption to higher-income groups. A marked feature of the system of personal exemptions under a progressive income tax, which distinguishes it from a system of social benefits or tax credits, is that the allowance is worth more to the higher-rate taxpayer than to the lower-rate taxpayer, since an increase in a personal exemption means that there is so much less income taxable at the highest marginal rate to which the taxpayer is liable. At the other extreme of the scale, an individual whose exemptions already exempt the whole of his income will gain nothing from an additional exemption. Hence, one might want to reject the use of the old age exemption on vertical equity grounds since the greatest beneficiaries are those who are least in need.

In short, one should abolish the old age exemption on equity (horizontal and vertical) as well as efficiency grounds. Indeed, anything (e.g., indexing) which leads to an increase in such an exemption is therefore undesirable. Similar arguments apply to the \$1,000 pension income deduction which was introduced in 1975, supposedly to compensate individuals in some way for the deleterious impact of inflation on the purchasing power of retirement savings. Like the old age exemption, this deduction is inequitable and there is no empirical evidence to suggest that it encourages retirement saving.

The tax expenditures (i.e., revenue loss) associated with the old age exemption could instead be used to finance an expanded Guaranteed Income Supplement as well as more generous provincial supplements to the elderly, while those tax expenditures on the pension income deduction could be channelled into a more equitable programme to encourage saving for retirement. 16

#### (2) A More Equitable Incentive to Retirement Saving

On the other hand, our empirical evidence does lend support to the conventional wisdom that, as a result of the tax deductibility of contributions to employer-sponsored pension plans and especially RRSPs, such savings vary directly with average and hence the marginal rate of personal income tax. Thus, one would expect participation in employer-sponsored pension plans and especially RRSPs to be largely confined to taxpayers in the upper-income brackets not just because of their income, but also by virtue of the fact that they have more to

In this regard, it is useful to indicate the tax expenditures or revenue loss associated with both the old age exemption and pension income deduction. Estimates by the Economic Council of Canada show that if the old age exemption had been abolished for the 1977 tax year, federal and provincial government tax revenues would have increased by \$142 million and \$68 million respectively, while removal of the pension income deduction in the same year would have increased federal and provincial government revenues by \$90 million and \$42 million respectively. If the old age exemption as well as the pension income deduction had been abolished together, they would have increased federal government revenue by \$248 million and provincial governments' revenue by \$117 million, a total of \$365 million in 1977.

gain in terms of tax saving due to their income but their higher marginal tax rates. Indeed, according to Statistics Canada, of the almost 1.3 million taxpayers who reported RRSP contributions in 1976, nearly 86 percent had earnings of \$10,000 or more. While the averge contribution was \$1,638, taxpayers in the higher earning bracket contributed average amounts ranging from \$1,053 for those in the \$10,000-\$14,000 range and \$2,978 for those who earned \$25,000 or more.

What this suggests is that lower income groups may fail to save for their retirement not simply because they have insufficient income but because there is little incentive to do so. Since their incomes are low, implying a low marginal tax rate, the tax saving on employer-sponsored pension plans and especially RRSP contributions will be small. It follows, therefore, that if the lower income groups were offered tax savings on such contributions similar to those accorded to higher income groups, they might be tempted to save more for their retirement.

This might be done through a new kind of RRSP, whereby the government would pay low-income contributors a bonus in order to compensate them for their low tax saving resulting from the tax deductibility of RRSP contributions 17. While this type of RRSP would

<sup>17</sup> See (Daly, 1980).

be quite innovative, it should be pointed out that a system of government bonuses for saving by lower income groups has been operating successfully in West Germany for a number of years, and has been justified on vertical equity grounds.

### APPENDIX "A"

## Definitions and Sources of Variables

Symbol	Definition
R <sub>1</sub>	Real, per capita gross annual contributions to Registered Retirement Saving Plans (RRSP) by individuals less than 65 years of age.
R <sub>2</sub>	Real, per capita employer-sponsored pension plan savings defined as annual employee contributions to Registered Pension Plan.
a	Real, per capita expected benefits from the Old Age Security program, corrected for a change in the age of eligibility in 1972.
p	Real, per capita employer-sponsored pension plan wealth defined as the book value of the stock of assets held by trustees, trust and insurance companies.
S	Real, per capita expected net benefits from the Canada and Quebec Pension Plans excluding future tax liabilities.
r	The yield on Trust Certificates of 5 years or more.
m <sub>1</sub>	A proxy for the marginal tax rate defined as $1/(1-t_1)$ where $t_1$ is the ratio of Total Tax Payable over Taxable Income in Period 1.
<sup>m</sup> 2	A proxy for the marginal tax rate defined as $t_2/(1-t_2)$ where $t_2$ is defined as above for period 2. The average tax rate equals the marginal tax rate in a proportional tax system.
е	Real, per capita Old Age Exemptions applicable to taxable income of individuals 65 years and older.
E	Nominal, per capita Old Age Exemptions as defined above.
у <sub>1</sub> , у <sub>2</sub>	Real, per capita assessed personal income from all sources as defined by the Income Tax Act for individuals less than age 65 $(y_1)$ and aged 65 years and older $(y_2)$ .
Y <sub>1</sub> , Y <sub>2</sub>	Nominal, per capita assessed personal income as defined above.
x <sub>1</sub> , x <sub>2</sub>	Nominal, per capita Personal Exemptions as defined by the Income Tax Act for individuals less than age 65 $(X_1)$ and aged 65 years and older $(X_2)$ . The latter excludes Old Age Exemptions.

Definition Symbol Nominal, per capita deductions as defined by the Income Tax  $D_1$ ,  $D_2$ Act excluding all pension plans contributions (RRSP, CPP/QPP and Registered Pension Plans) for individuals less than age 65 (D1) and all deductions for individuals aged 65 and over (D2). Nominal, per capita pension plan contributions by  $K_1$ individuals less than age 65 as defined above. A time trend for the period 1964 to 1976. T S Since the data are time series disaggregated by sex, a dummy, O for observations on males and I for observations on females is required.
