NOTE

## Kill of Greater Snow Geese in Quebec

## 1978-80

by C. Hyslop ${ }^{1}$ and S. Wend

## Introduction

The population of Greater Snow Geese grew drama tically in the 1970s. When the population was smaller, almost all of it staged in the vicinity of Cap Tourmente National Wildlife Area (NWA). The importance of CWS. In 1972 the population was large enough for the introduction of a controlled hunt at the NWA, and by 1978 substantial levels of hunting had developed in other areas away from the NWA.
Although the National Harvest Survey (NHS) run by CWS gave estimates of an increasing kill, we wanted to NWA. We also had an opportunity to study bias in questionnaire surveys by comparing the response with bag-check data from the NWA

We conducted mail surveys in Quebec for the 197880 hunting seasons to determine the size and location of the annual kill of Greater Snow Geese, and com pared the data from these surveys with kill estimate from the NHS and data from the controlled hunt at Cap Tourmente NWA

## Methods

Each mail survey covered a stratified random sample of permit holders from the current year's Canada migratory game bird hunting (MGBH) permit sales. Since the sampling frame included only Quebec res idents, we had to investigate out-of-province hunter The basis for stratifications.
he parit whe place of purchas of the permit, which defined three geographic categor and non-renewal (Fig. 1). (Hunters who purchase MGBH permits the previous year are termed "renew als"). Both of these factors have been found to affec kill in the NHS, and the data were readily available at sample selection time
We defined the geographic strata and determined the optimal allocation of the sample among them by using NHS in previous years.

The questionnaire asked respondents to assign their kill to one of seven zones (Fig. 2). These zones were designed primarily to locate kill along the St. Lawrence

CWS, Ottawa, Ont. KIA OE7
estuary north of Quebec City, where the majority of Greater Snow Geese congregate during the fall migration.

Zone 2 included only the controlled hunt at Cap Tourmente NWA, but hunters not registered in thi
hunt often assigned their kill to this zone.
In the third year's survey (1980-81), we changed the questionnaire map slightly to try to reduce this source of error. Zone 2 was delineated by a small rectangle with the words "National Wildlife Area only" added to its caption.

## Results

Sample allocation
To determine the gain in efficiency from using a stratified sample rather than a simple random sample, we compared harvest estimate variances with estimates of the variance that would have resulted from simple random sampling (Cochran 1977). Table 1 shows th omparison by zone of kill
expected the estiman usually increases the precision we expected the estimated variances from simple raneys. For the most part this was true; however, there were some reversals of this tendency, as shown in Table 1.
It seemed that our allocation based on previous experience from the NHS was less than optimal for hunting zones 4 and 7 . This indicates a shift in hunting practices in recent years that has changed the contribu tions that would have been best in the years before our surveys were no longer optimal. To find out which strata were involved, we calculated a new allocation of our sample based on the variances obtained in these surveys for total kill throughout the province.
Table 2 shows the number of questionnaires mailed to each stratum on the basis of the original allocations, the number of responses received, total kill and days hunted reported, and the revised allocation. Stratum A and stratum C (1978 nder-allocated

sampling to be larger than those in stratified surveys.
(no kill was reported from hunters in stratum C in 1979) (Table 2). Sampling in this stratum should have been greater both because of the changing pattern of snow-goose hunting (see results), and to
the lower response rate from this group.
Response rates to the NHS in Quebec were $64 \%$ in 1980, $61 \%$ in 1979, and $70 \%$ in 1978 (Wendt and Hyslop 1981, 1980; Wendt et al. 1979). The higher response to this special survey may be due to the fact exclusively in Quebec and is highly regarded in that province. The nu
questionnaires over the hunters responding to the total number of respondents (Tables 3 and 4). This trend establishes that hunter activity is growing in response to the Greater Snow Goose populations

Active hunters from stratum A, local to the birds' staging areas, contributed the highest proportion of the kill per hunter, and generally renewal hunters were more successful and spent more days hunting than nonrenewal hunters in each geographic stratum (Table 3).

The estimated numbers of geese killed and days hunted, based on reported numbers and the extrapolation factors, are given by zone of hunt for each year in Table
The harvest for the 3 years was centred in zones 4 and 6 (Fig. 2, Table 5). These two zones contributed $47 \%$ of the kill in $1980,54 \%$ in 1979, and $44 \%$ in

The number of days devoted to the hunt was great est in zone 7 , followed by zone 6 , with $62 \%$ of the days
hunted spent in zones 7 and 6 in 1980, $54 \%$ in 1979, nd $61 \%$ in 1978. The controlled hunt at Cap Tour1980, 1979, and 1978 seasons respectively,
Table 6 compares the estimated numbers of geese killed with NHS estimates for the kill of Greater Snow Geese in Quebec. To ensure a standard definition for the NHS estimates, we included all non-Canada geese killed in Quebec away from known areas of Lesser Snow Goose migration. NHS estimates were within the confidence intervals for estimates from this survey each season: the values were $5-15 \%$ different.
The proportion of the NHS kill by hunters not resiributed only 1-30 of the total kill, we were justified in not including this group in our sampling frame.

Hunters who stated on their questionnaires that they hunted in zone 2 (Cap Tourmente NWA), but whose names did not appear in the list of Cap Tourmente
registered guests, were reassigned to another zone. We placed them in either zone 1 (the zone immediately sur province not included in zones 1 to 6 ) if they had also hunted in zone 1 .

The number of hunters that this correction was made for and their estimated harvest are reported in Table 7. Changing the questionnaire to improve the identification of zone 2 seems to have had the desired effect of reducing the number of errors. The percentage of the harvest wrongly assigned to this zone decreas to only $5 \%$ in 1980-81 from 10-13\% in 1978-79.

## Zone 2 bag-check comparison

We determined the number of geese harvested at the Cap Tourmente controlled hunt by a bag-check and compared them with the corrected estimates of the zone 2 harvest (Table 8). Although the estimates differed from $9-48 \%$, all bag-check totals were within the confidence limits for the survey estimates except in one case (days hunted in 1978-79)

## Discussion

The total kill for the three seasons (Table 5) shows an Therease in keeping with the trend for both Cans and American harvests over several years (Reed et al. 1981). Canadian kill accounted for $23.9 \%$ of the estimated fall flight in 1980, $14.5 \%$ in 1979 , and $18 \%$ in 1978 (fall flight estimates from Reed, pers. comm.). The combined Canadian and US sport harvest took $32.8 \%$ of the population in $1980,22 \%$ in 1979, and $25 \%$ in 1978. These are significant proportions of th total population. Reed et al. (1981) estimated an av

The close correspondence of total kill estimates in our surveys to comparable NHS estimates indicates tha the NHS performs well in provincial estimates for this species (Table 6). But when we tried to use NHS result for small areas, we found that we could not separate example, we could not reliably separate zone 3 (L'Ile d'Orleans) from zone 1 in the national survey data. When intricate results such as this are required, special surveys must be used.

## Acknowledgements

Among the many people who helped or gave advice fo these surveys, we especially thank A. Reed, G.E.J. Smith, F.G. Cooch, H. Boyd, F. Filion, and L.
Teevens.

| 6 | 9949 | 1 | 5 574-14 324 | 10160 | 2 | 7 361-12 959 |
| 7 | 6010 | 4 | 2596-7736 | 16121 | 1 | 3 802-27 144 |
| Total | $43360 \dagger$ |  | 35 282-50 927 | $43104 \dagger$ |  | 30 761-56244 |

Order of magnitude from largest to smallest for comparative
purposes.
Totals are greater than the sum of the zone totals because zone of
hunt was not specified on some questionnaires.

## Table 6

Comparison of kill estimates with National Harvest
Survey estimates

|  | 1980-81 |  | 1979-80 |  | 1978-79 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Kill | Confidence interval | Kill | Confidence interval | Kill | Confidence interval |
| Total kill estimate for all zones | 71899 | 60 637-83 161 | 31830 | 26 476-37 184 | 43360 | 35 282-50 927 |
| NHS estimated Greater Snow |  |  |  |  |  |  |
| Goose kill in Quebec | 61862 | - | 34095 | - | 40339 | - |
| Kill in Quebec by non-resident |  |  |  |  |  |  |
| hunters (NHS estimates) | 788 | - | 267 | - | 1432 |  |
| \%* | 116 | - | 93 | - | 107 | - |

*Estimates from this survey as \% of NHS estimates.
