No. 84, May 1978

The co-operative Breeding Bird Survey in Canada,

by G.H. Finney, 1 K.E. Freemark 1 and A.J. Erskine 2

Introduction

The Breeding Bird Survey (BBS) has been active in Canada since 1966. This co-operative effort attempts to measure year-to-year and long-term changes in populations of birds (especially smaller land birds) in settled areas of Canada. The BBS is limited mainly by the availability and distribution of qualified observers and of all-weather roads. The roadside method of surveying (Erskine 1978) precludes strictly natural habitats and incorporates an edge effect. An advantage of the BBS method, however, is that it samples larger numbers of individual birds relative to the time spent than almost any other type of ground survey. The BBS also enables detection of widespread or continuing changes in relatively common bird species, in time to take appropriate action. This report compares 1976 and 1977 data and considers the changes in bird populations over the last 5 years. It is similar in format and coverage to recent reports (cf. Erskine 1975, 1976, 1977). A report covering the first 10 years of the BBS in Canada has recently been published (Erskine 1978).

The Canadian Wildlife Service and the United States Fish and Wildlife Service co-ordinate the BBS while the surveys are done by volunteers and professional ornithologists. Methods of data collection are the same throughout, but procedures for editing and analysing data are revised as better methods are developed. The senior author directed the data analysis, in consultation with Dr. Erskine, who had been national co-ordinator until this year.

Results

Coverage

Figure 1 shows the distribution of degree-blocks in which surveys were made in 1977, compared with past coverage. Table 1 shows the actual numbers of routes surveyed in each of the last 5 years and the total number of routes surveyed since the survey began in 1966. In the Maritimes and in southern parts of Quebec, Ontario, and British Columbia, most degree-blocks contain two routes each; therefore the coverage is somewhat less complete than Figure 1 indicates.

SK 471 C3371 ND .84

Grouping of routes for analysis

The 1976 groupings were used again, with minor adjustments. The species detected in greatest numbers in each region are shown in Tables 2-8; the species most frequently detected along the route near Churchill, Manitoba, are shown in Table 9.

Changes observed

00 22722 F

Analyses cover six major regions of Canada, as in recent years. Summaries of comparisons for the Maritimes, central Ontario and central Quebec, southern Ontario and southern Quebec, southern Prairie Provinces, central Prairie Provinces, and British Columbia (west of the Rockies) between 1976 and 1977 are presented in Tables 10–15. Although data for about 60 species were analysed for each region, only the comparisons made for species reported previously (cf. Erskine 1975, 1976, 1977) are presented here. Indices of relative abundance of those species are presented for the last 5 years for each region in Tables 16-21. For those analyses, 1973 estimates of abundance were fixed at an index value of 100. With 5 years of information now available for British Columbia, this is the first year that trends for this region have been seriously analysed.

Discussion

Coverage

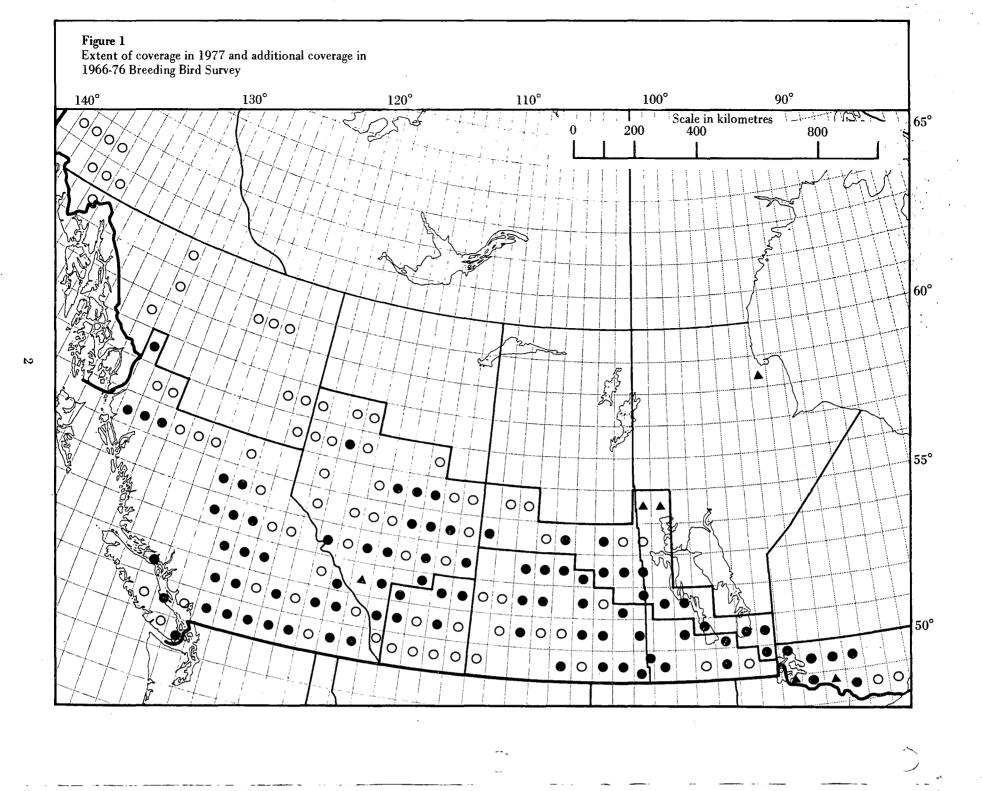

The pattern of coverage differed only in detail from past years. The general downward trend in the number of routes surveyed continued into 1977. No routes were surveyed in the Yukon Territory or on the island of Newfoundland. Far fewer routes were surveyed in Alberta this year. More routes were surveyed than in previous years only in Manitoba, where three new routes were added in the north. Surprisingly, many of the gaps in coverage are near major population centres (e.g. Edmonton, Regina, Winnipeg, Montreal, Quebec City) where most competent observers live and where it should be easy to recruit more co-operators. While it is preferable that the same observer surveys a route each year, a survey by another observer, who may continue the following year better than no survey at all. An observer change means trie route cannot be included in comparisons for the current year. but it may be comparable in the following year, which would otherwise be lost.

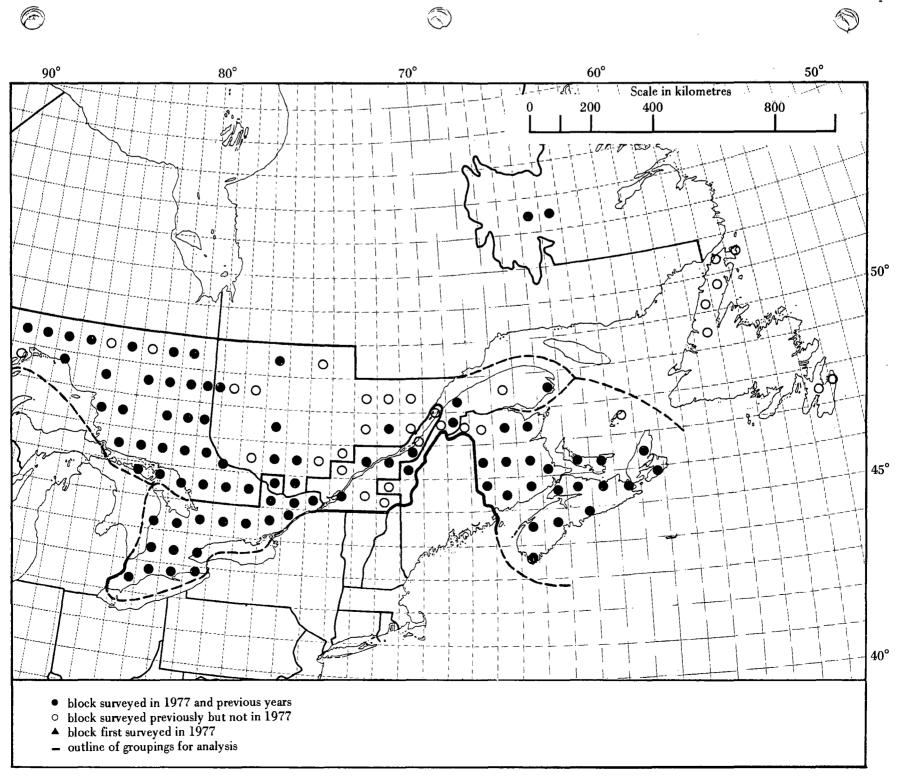

Of routes covered in both 1976 and 1977, 79% were comparable. Only in the southern Prairie Provinces (69%) were fewer than 77% of routes comparable. Of 38 routes which were surveyed in both 1976 and 1977 but which were not comparable, only 12 had observer changes while 14 had survey dates differing by 20 or more days between years or with one or both dates outside the allowable period (i.e. after 7 July). The other 12 were rejected for combinations of reasons, often including adverse weather. To ensure the collection of useful data, we emphasize the need to survey routes within the specified calendar period and as close to past survey dates as possible.

Grouping of routes for analysis

No changes were made this year, despite the marginally adequate samples again available from the Prairie Province

¹CWS, Ottawa, Ont. K1A 0E7. ²CWS, Sackville, N.B. E0A 3C0.

ဃ

regions. The central Prairie Province region does not incorporate northeastern British Columbia, as no routes were surveyed in that area in 1977. Until the number of comparable routes is significantly increased in the current BBS coverage or the BBS coverage area is expanded, it is unlikely that the present analysis pattern of six major regions can be improved.

Changes observed

In 1977 more species decreased than increased significantly in numbers in all regions except the central Prairie Provinces (Tables 10 to 15). In the Maritimes, Yellow-bellied Sapsucker, Winter Wren and Ruby-crowned Kinglet all plummeted dramatically in numbers to their lowest levels since the surveys began (Tables 3 and 16; Erskine 1978), apparently in response to the severe winter in the southeastern United States. Brown-headed Cowbird, Common Flicker, Nashville Warbler and Dark-eyed Junco, all of which seemed to be declining up to 1975 (Erskine 1978), appeared to be stable in 1977. Only House Sparrow and Common Yellowthroat increased significantly in numbers, although Red-eyed Vireo, Ovenbird and American Redstart also continued their upward trend.

Winter Wren and Ruby-crowned Kinglet declined dramatically and significantly in the central Ontario and central Quebec region; the Yellow-bellied Sapsucker population index was nearly unchanged between 1976 and 1977. The Song Sparrow population index also decreased significantly. Winter Wren was at its lowest level since 1969, the first year of the BBS in this region, and Song Sparrow and Ruby-crowned Kinglet population indices have never been lower (Tables 4 and 17; Erskine 1978). The decline for Ruby-crowned Kinglet and Winter Wren is made the more dramatic because of their previous steady increases since the BBS began in central Ontario and central Quebec (Erskine 1978). Meanwhile, population indices for both Mourning Warbler and American Redstart increased significantly. For American Redstart this renews a general upward trend noted by Erskine (1978) up to 1975, which was briefly halted in 1976. Among other species of interest, both Brown-headed Cowbird and Red-winged Blackbird showed little change, while population trends for Blue Jay, Cedar Waxwing and Rose-breasted Grosbeak remained decidedly uncertain.

In southern Ontario and southern Quebec, six species showed significant decreases while only two, Barn Swallow and Red-winged Blackbird, increased significantly. Both species have increased steadily in numbers since 1973. Gray Catbird and Rock Dove again increased between 1976 and 1977, although not as significantly as during the past five surveys. Among the species that declined was this region's representative of the genus Troglodytes, the House Wren, which also winters in the southeastern and southcentral United States. This decline followed successive increases since 1974. Warbling Vireo also decreased in numbers after increases in three successive years, while the decline in Northern Oriole in 1977 followed a significant increase in 1976. Blue Jay was at its lowest level (49% of 1973 level) since the surveys began in this region in 1968, perhaps also

a victim of the unusually cold and snowy eastern North American winter. Rose-breasted Grosbeak also declined, reversing a trend in evidence to 1975 (Erskine 1978). Killdeer also declined significantly between 1976 and 1977. The population indices suggest that Cedar Waxwings may be slowly declining in numbers although individual annual changes have not been significant. In southern Ontario and southern Quebec Starling continued a strong and steady increase, in evidence since 1968 (Erskine 1978).

In the southern prairie region, seven species declined significantly in numbers between 1976 and 1977, while none increased. Franklin's Gull, Starling, Yellow-headed Blackbird and Common Grackle declined to more usual levels after reaching extremely high numbers in 1976. Lark Bunting declined dramatically to its lowest level since the start of analyses of prairie birds in 1970, but this is not unexpected in light of the extreme fluctuation in population indices which is evident for this species between years. The most notable change in the southern Prairies is the decline of Sora to its lowest level during the survey period, after a strong and fairly steady increase since 1970. Among species not showing significant changes between 1976 and 1977, Rock Dove and Mourning Dove remained at their high 1976 levels, and House Wren and Red-winged Blackbird were stable. It bears repeating that, with only 18 comparable routes in 1976-77, accurate interpretation of BBS trends in the southern Prairies is quite tenuous. We hope that volunteers will come to the rescue and increase this number so that in the near future we do not have a gap in our annual data.

In the central prairie region, populations of four species declined while those of seven increased. Among waterbirds. Lesser Scaup were down while American Coot and Northern Shoveler both increased. Starling, Dark-eyed Junco and Pine Siskin all declined significantly following large increases between 1975 and 1976. Clay-coloured Sparrow and Redwinged Blackbird population indices rose significantly in 1977 following significant declines a year earlier. Compensatory changes, as were recorded for these species and several others in the southern Prairies, may reflect real population recoveries but more likely reflect local observation difficulties in one year (e.g. poor weather, unusual bird distribution or timing). Red-eved Vireo continued to recover from a substantial decline due to a cold spring in 1974 and the increase in Black-billed Magpie completes the list of species which showed a significant change.

The most notable changes in Canada took place in British Columbia where, of 10 species changing significantly in numbers, only Starling showed an upward trend. Among those showing a significant decline, Western Wood Pewee, Black-capped Chickadee, Orange-crowned Warbler, House Sparrow and Pine Siskin reached their lowest level of the 5 years of the BBS. A consistent downward trend is suggested for Black-capped Chickadee and possibly Cedar Waxwing, which has declined in each year of the survey but never significantly. American Robin, Varied Thrush, Dark-eyed Junco and Song Sparrow all declined following large increases between 1975 and 1976. Among those species not showing a significant change in 1977, Common Flicker and

Rufous-sided Towhee are both of note as they remained at their relatively high levels of 1976.

Throughout Canada, 1977 was apparently not a very good year for birds. The winter of 1976—77 obviously took its toll on some species, notably Ruby-crowned Kinglet and Wrens in eastern Canada; but, surprisingly, thrushes and sparrows, which winter in the same general area, were not markedly affected. Changes in the Prairies may best be attributed to a dry winter and early spring followed by a wet May and June in many places. Causes for the changes in British Columbia are not known.

The continued decline in route coverage is presently our major concern. Now that the BBS has been active for at least 5 years in all provinces of Canada, real trends ought to become more evident, making the results more useful as an ecological early-warning device.

Acknowledgments

We wish to thank all observers and assistants plus the regional co-ordinators for their fine efforts and urge them to recruit competent observers, especially in regions where route coverage is declining.

Addresses of the co-ordinators are:

Newfoundland: co-ordinated from CWS, Ottawa K1A 0E7

New Brunswick, Nova Scotia, Prince Edward Island: Mr. David S. Christie, The New Brunswick Museum, 277 Douglas Avenue, Saint John, N.B. E2K 1E5

Quebec: Club des Ornithologues de Québec, 8191, avenue du Zoo, Orsainville G1G 4G4

Ontario: Dr. J. Murray Speirs, 1815 Altona Road, Pickering L1V 1M6

Manitoba: Mr. H.W.R. Copland, Manitoba Museum of Man and Nature, 190 Rupert Avenue, Winnipeg R3B 0N2

Saskatchewan: Dr. J.B. Gollop, CWS, 115 Perimeter Road, Saskatoon S7N 0X4

Alberta: Mr. Jack L. Park, 10236-70 Street, Edmonton T6A 2T4

British Columbia: Mr. R. Wayne Campbell, British Columbia Provincial Museum, Victoria V8W 1A1

Yukon Territory: co-ordinated from CWS, Ottawa K1A 0E7
