TECHNICAL REPORT SERIES
CANADIAN WILDLIFE SERVICE

This series of reports, established in 1986, contains technical and scientific information from projects of the Canadian Wildlife Service. The reports are intended to make available material that either is of interest to a limited audience or is too extensive to be accommodated in scientific journals or in existing CWS series.

Demand for these Technical Reports is usually confined to specialists in the fields concerned. Consequently, they are produced regionally and in small quantities; they can be obtained only from the address given on the back of the title page. However, they are numbered nationally. The recommended citation appears on the title page.

Technical Reports are available in CWS libraries and are listed with the DOBIS system in major scientific libraries across Canada. They are printed in the official language chosen by the author to meet the language preference of the likely audience. To determine whether there is significant demand for making the reports available in the second official language, CWS invites users to specify their official language preference. Requests for Technical Reports in the second official language should be sent to the address on the back of the title page.

SÉRIE DE RAPPORTS TECHNIQUES
DU SERVICE CANADIEN DE LA FAUNE

Cette série de rapports donnant des informations scientifiques et techniques sur les projets du Service canadien de la faune (SCF) a démarré en 1986. L'objet de ces rapports est de promouvoir la diffusion d'études s'adressant à un public restreint ou trop volumineuses pour paraître dans une revue scientifique ou l'une des séries du SCF.

Ordinairement, seuls les spécialistes des sujets traités demandent ces rapports techniques. Ces documents ne sont donc produits qu'à l'échelon régional et en quantités limitées; ils ne peuvent être obtenus qu'à l'adresse figurant au dos de la page titre. Cependant, leur numérotage est effectué à l'échelle nationale. La citation recommandée apparaît à la page titre.

Ces rapports se trouvent dans les bibliothèques du SCF et figurent aussi dans les listes du système de référence DOBIS utilisé dans les principales bibliothèques scientifiques du Canada. Ils sont publiés dans la langue officielle choisie par l'auteur en fonction du public visé. En vue de déterminer si la demande est suffisamment importante pour produire ces rapports dans la deuxième langue officielle, le SCF invite les usagers à lui indiquer leur langue officielle préférée. If faut envoyer les demandes de rapports techniques dans la deuxième langue officielle à l'adresse indiquée au verso de la page titre.

ABSTRACT

Aerial surveys for bird abundance and distribution were conducted in August 1991 at McKinley Bay, NWT. This bay is the site of a winter harbour for drillships and proposed location for a major year-round support base for oil and gas exploration in the Beaufort Sea. The 1991 surveys represented the continuation of a long-term monitoring study of birds in McKinley Bay and Hutchison Bay, a nearby area used as a control. The primary objectives of the 1991 surveys were to expand the set of baseline data on natural annual fluctuations in diving duck numbers, and to determine if numbers of diving ducks had changed since the initial set of surveys, from 1981 to 1985.

Survey techniques were identical to previous years. A series of east-west transects was flown across each bay and adjacent terrain. The study areas were divided into three components: bay, terrestrial, and outside.

The best survey conditions in early August of 1991 occurred on August 7. Based on the survey data from that day, the estimated population of diving ducks at McKinley Bay was 31 592 ± 7953. On average, in 1990 and 1991, significantly more diving ducks utilized McKinley Bay than in the years from 1981 to 1985 ($p<0.05$). Most of the increase in total diving duck numbers was due to significantly greater numbers of Oldsquaw ($p<0.05$).

At Hutchison Bay, there were only an estimated 11 111 ± 771 diving ducks on August 7, 1991. Again, Oldsquaw and scoters were the most common species. The 1991 results differed from all other years of surveys, in that fewer diving ducks were recorded on the bay component at Hutchison Bay than at McKinley Bay in 1991. The low counts at Hutchison Bay may reflect local changes in diving duck distribution within Hutchison Bay and adjacent bays providing similar habitat (especially Parliayut Bay). Because of the large variation in numbers of diving ducks observed at Hutchison Bay in 1990 and 1991, it is recommended that another year of aerial surveys be carried out.

As in previous years of surveys at McKinley Bay, large numbers of diving ducks were observed off Atkinson Point, at the south end of the bay and in the northeast corner near a long spit in 1991. Most divers seen in Hutchison Bay were at the west side of the bay, close to Warren Point.

Diving ducks, primarily Oldsquaw and scoter, were the most abundant bird group in the study area, but Northern Pintail, Greater White-fronted Geese, Brant, Tundra Swans, Red-throated Loons, Pacific Loons, Arctic Terns and Glaucous Gulls were also recorded frequently. Observed distribution patterns of birds are discussed with reference to habitat preferences.

RÉSUMÉ

Des relevés aériens sur la quantité d'oiseaux et leur répartition ont été menés en août 1991 à la baie McKinley (T. N.-O.). Il s'agit d'un port d'hivernage pour les navires de forage pétrolier, et ils on propose d'en faire une importante base de soutien permanente pour l'exploration du pétrole et du gaz dans la mer de Beaufort. Les relevés effectués en 1991 faisaient partie d'une étude de surveillance à long terme des oiseaux à la baie McKinley et à la baie Hutchison (région située tout près et utilisée comme aire témoin). Les objectifs principaux des relevés de 1991 étaient d'obtenir un plus grand nombre de données de référence sur la variation annuelle naturelle des effectifs de canards plongeurs et de déterminer si le nombre de canards plongeurs avait changé depuis la phase initiale des relevés, qui avait eu lieu de 1981 à 1985.

Les mêmes techniques que celles des années précédentes ont été utilisées. Une série de transects a été tracée en direction est-ouest à travers chaque baie et chaque terrain adjacent. Les régions d'étude ont été divisées en trois éléments: la baie, les terres et l'extérieur.

Les conditions d'étude ont été optimales le 7 août. Selon les données obtenues lors de cette journée, la population estimative de canards plongeurs à la baie McKinley était de 31 592 ± 7 953. En moyenne, en 1990 et 1991, un nombre beaucoup plus important de canards plongeurs ont fréquenté la baie McKinley, comparativement à la période allant de 1981 à 1985 ($p < 0,05$). Cette augmentation des effectifs de canards plongeurs était due, en grande partie, au nombre beaucoup plus important de Canards kakawis ($p < 0,05$).

À la baie Hutchison, on a estimé qu'il y avait seulement 11 111 ± 771 canards plongeurs le 7 août 1991. Une fois de plus, le Canard kakawi et les macreuses étaient les plus nombreux. Les résultats du relevé de 1991 diffèrent de ceux de toutes les autres années pour ce qui est du nombre de canards plongeurs, qui était inférieur dans l'élément baie de la baie Hutchison par rapport à la baie McKinley. Le faible nombre à la baie Hutchison peut être dû aux changements de répartition des canards plongeurs à la baie Hutchison et aux baies adjacentes qui offrent un habitat similaire (particulièrement la baie Parliayut). En raison de la variation importante du nombre de canards plongeurs observés à la baie Hutchison en 1990 et en 1991, on recommande que des relevés aériens soient menés pendant une autre année.

Une fois de plus, lors des relevés effectués à la baie McKinley en 1991, un grand nombre de canards plongeurs ont été observés près de la pointe Atkinson, à la limite sud de la baie et dans sa partie nord-est, près d'une longue langue de terre. La plupart des canards plongeurs observés à la baie Hutchison se trouvaient sur le côté ouest de la baie, près de la pointe Warren.

Dans l'aire d'étude, les canards plongeurs (particulièrement le Canard kakawi et les macreuses) étaient les oiseaux qui étaient présents en plus grand nombre. Cependant, on y a également observé le Canard pilet, l'Oie rieuse, la Bernache cravant, le Cygne siffleur, le Huart à gorge rousse, le Huart du Pacifique, la Sterne arctique et le Goéland bourgmestre. Les modèles observés de répartition des oiseaux sont traités par rapport aux préférences d'habitat.

ACKNOWLEDGEMENTS

The authors are grateful to the following people for their contribution to the study in 1991. Nick Vanderkooy of Canmar Marine Drilling Ltd., Scott Edwards of Indian and Northern Affairs Canada and Ken Hall of the Government of the Northwest Territories provided information regarding industrial activity in the Beaufort Sea in 1991; Inuvik Air Charter Ltd. pilot, James Gruben, flew the surveys; Wilson Visuals drafted the figures; and Mona Regnier and Doreen Gratton typeset the manuscript.

The study was jointly funded by the Northern Oil and Gas Action Program and the Canadian Wildlife Service with additional logistical support from Polar Continental Shelf of the Department of Energy, Mines and Resources.

1.0 INTRODUCTION

McKinley Bay is a shallow protected bay along the eastern Beaufort Sea coastline in the Northwest Territories. Each year, it provides important habitat for tens of thousands of diving ducks which migrate there in summer to moult.

Since 1979, McKinley Bay has been the site of a winter harbour and support base for oil and gas exploration in the Beaufort Sea. A brief history of the industrial development of the bay, and a summary of recent industrial activity, are included in Appendix A. Major activities such as dredging operations directed towards the continued development of the bay have not occurred since 1981. Although the support base at McKinley Bay remains active, there has been very little offshore drilling in the Canadian Beaufort Sea since 1985. However, in the future, this bay may become a major year-round support base for Beaufort Sea oil and gas drilling activity.

The Canadian Wildlife Service initiated a study in 1981 to monitor the effects of industrial development and activity on bird populations using the bay. The objective of the study was to collect baseline information on natural annual fluctuations in numbers of birds, in order to detect potential changes in bird use of the bay due to harbour development. Hutchison Bay, an undeveloped bay of similar size about 45 km to the west, was also surveyed, starting in 1982, as a control. Emphasis throughout the study has been placed on moulting diving ducks, due to their abundance in both bays in midsummer. Results of the 5-year initial phase of the study were presented in an earlier report (Cornish and Dickson 1986).

Annual aerial surveys from 1981 to 1985 determined that, on the average, over 12 000 diving ducks, primarily Oldsquaw and scoters, occurred in McKinley Bay in early August each year, while an average of over 13 000 diving ducks utilized Hutchison Bay (Cornish and Dickson 1986). Numbers of scoters and Oldsquaw using McKinley Bay varied significantly in some years, although numbers of Oldsquaw were less variable than scoters (Cornish and Dickson 1986).

In order to collect a second data set for comparison with the earlier set of surveys, aerial surveys were resumed in 1990 at McKinley and Hutchison bays (Cornish et al. 1991), and repeated in 1991. The primary objective of the second set of surveys was to determine whether diving duck numbers had changed significantly in the five years since completion of the initial phase of the study. In 1990, more than twice as many diving ducks were found at both bays than on average during the five years from 1981 to 1985 (Cornish et al. 1991). This report summarizes the findings of surveys conducted in 1991, and compares the data from 1990 and 1991 to those from the first five years of surveys.

2.0 METHODS

2.1 Aerial Surveys

To allow comparisons between sets of data, the same survey methods were used during the 1991 surveys as in 1990 and from 1981 to 1985. East-west transects were flown 2 km apart (Figs. 1 and 2), in a Cessna 185 at an elevation of 30 m above ground level and at an average speed of 145 km/h. One observer on each side of the aircraft counted all birds seen within 180 m of that side, so that the total transect width was 360 m. Observations were dictated into tape recorders so that observers never had to look away from the transect. Counting bias due to differences in observer skill was reduced since observers during the 1991 surveys were the same individuals as throughout the rest of the study (with the exception of one of the observers in 1981).

It became apparent from surveys conducted in 1982 that the peak period of moult for diving ducks in the bay was the first two weeks of August (Cornish and Allen 1983), and that good survey conditions (calm sea and light cloud) were imperative for accurate survey results. Accordingly, each year surveys were conducted between August 1 and 10 on whatever days the survey conditions were expected to be suitable. The data from the survey with the best conditions, in terms of visibility of birds, were then used for the calculations.

The study area at McKinley Bay was divided into three components: the area inside McKinley Bay called the bay component, a terrestrial component, and a section of marine habitat outside McKinley Bay called the outside component (Fig. 1). The bay component encompassed saltwater areas within McKinley Bay, including exposed sandspits which were intermittently washed over by tides. Protected shallow lagoon areas, such as the small branching lagoon system east of Louth Bay and the long narrow lagoon extending about 7 km south of McKinley Bay, were considered terrestrial, as were all inland lakes. The area west of Atkinson Point, the small bay at the west end of transects 4 to 6, and the western half of transect 1 were considered the outside component. The areas of each component and the proportions surveyed are listed in Table 1. The total size of the study area was 306 km^2. The area of the bay component of the McKinley Bay study area was 108.5 km^2 and the terrestrial component was 158.5 km^2.

At Hutchison Bay, the study area was also divided into three components (Fig. 2). Again, marine areas within the bay, and sandspits intermittently washed over by tides, were considered bay component. The isolated lagoon at the east end of transect 4, the narrow, shallow channels of the bay along transects 6 and 7, and all inland lakes were included in the terrestrial component. The saltwater areas west of Warren Point and the area covered by the western half of transect 1 were considered outside component. Table 1 presents the areas of the components at Hutchison Bay and proportions surveyed.

The terms diving ducks and divers refer to ducks belonging to either Aythyinae or Merginae. References in the text to dabbling ducks or dabblers refer to surface-feeding ducks classed as Anatinae. Appendix B lists the common and scientific names of species discussed in this report.

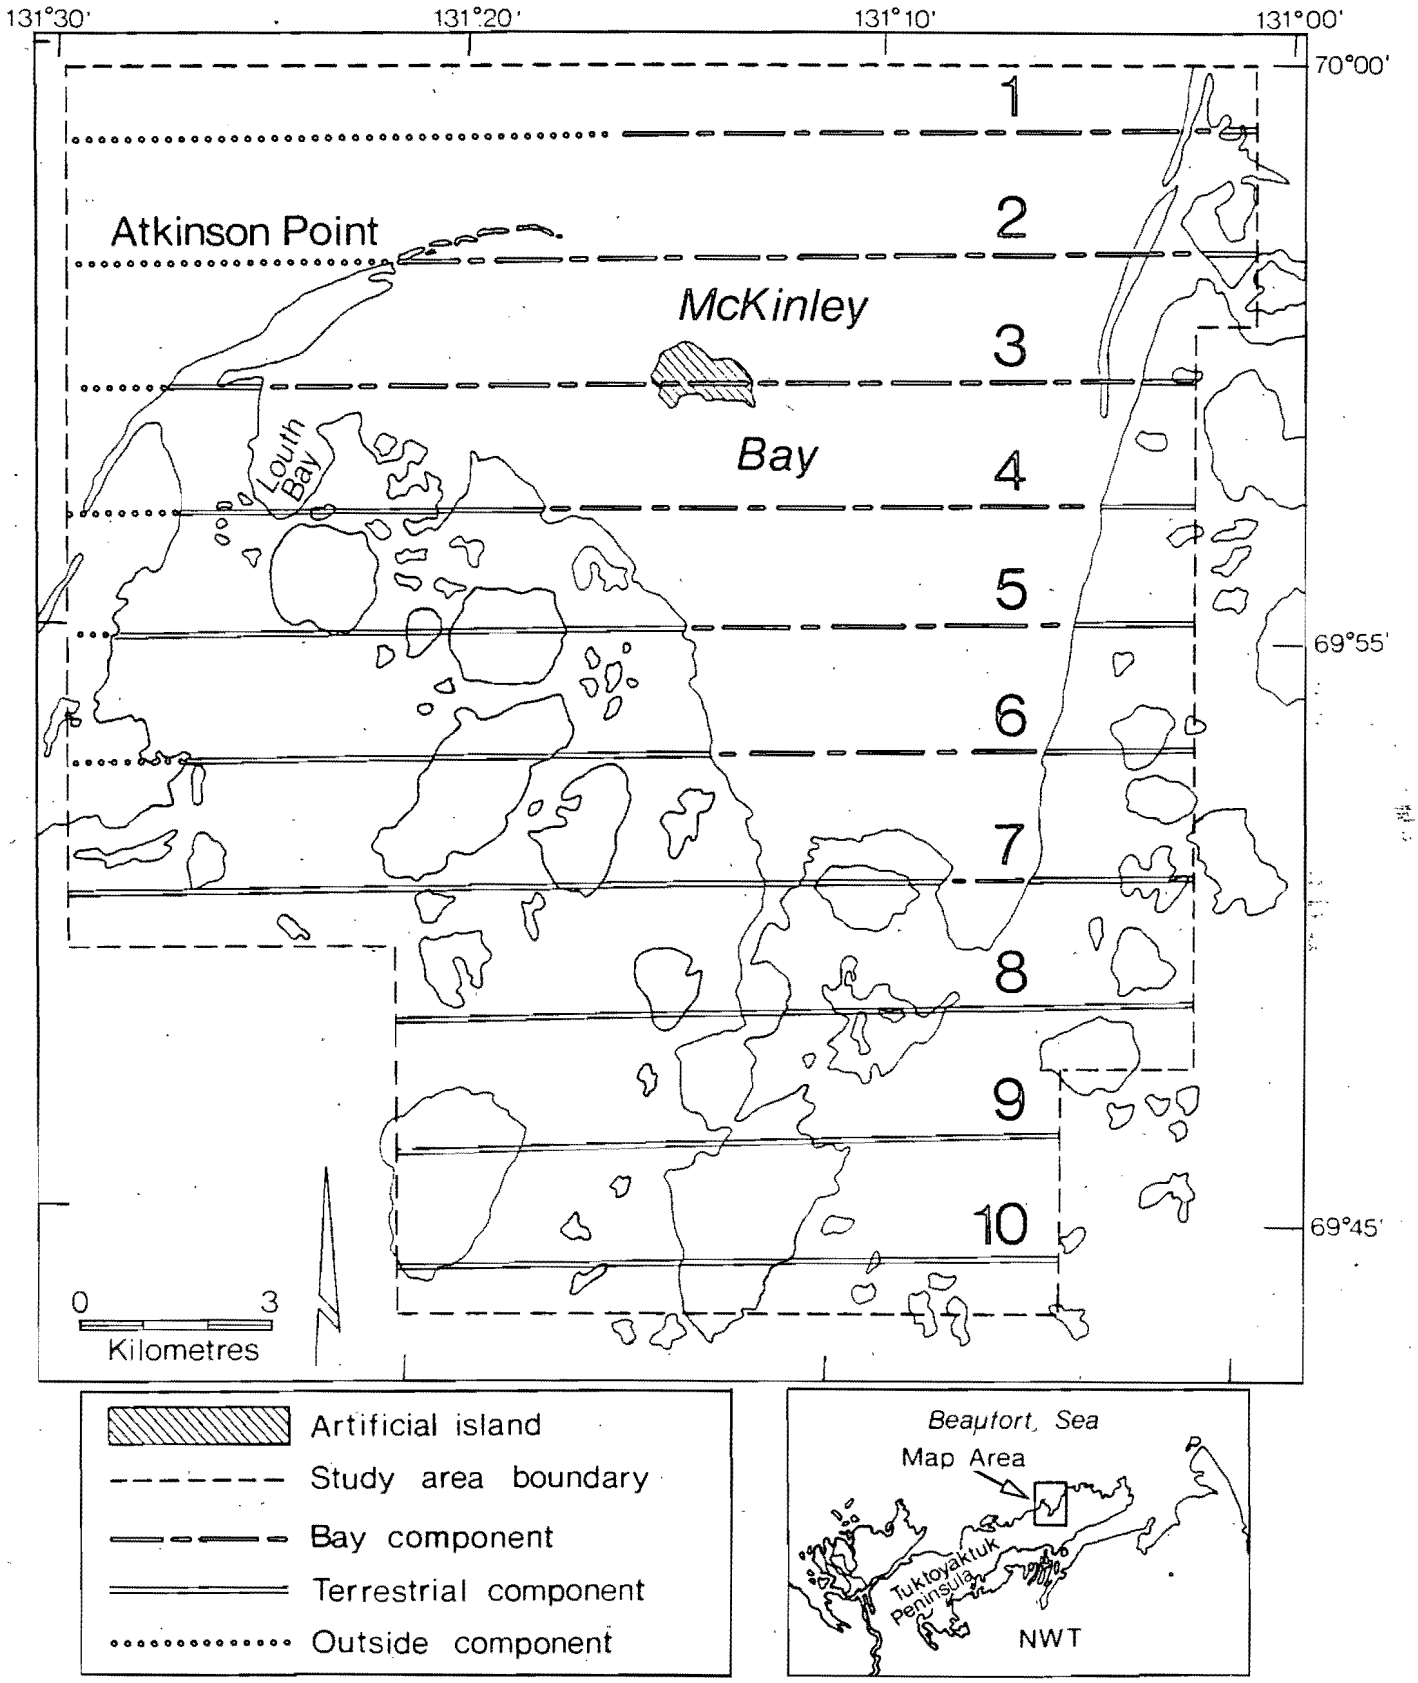

Figure 1. Aerial transects flown at McKinley Bay on August 7, 1991, showing the bay, terrestrial and outside components of the study area.

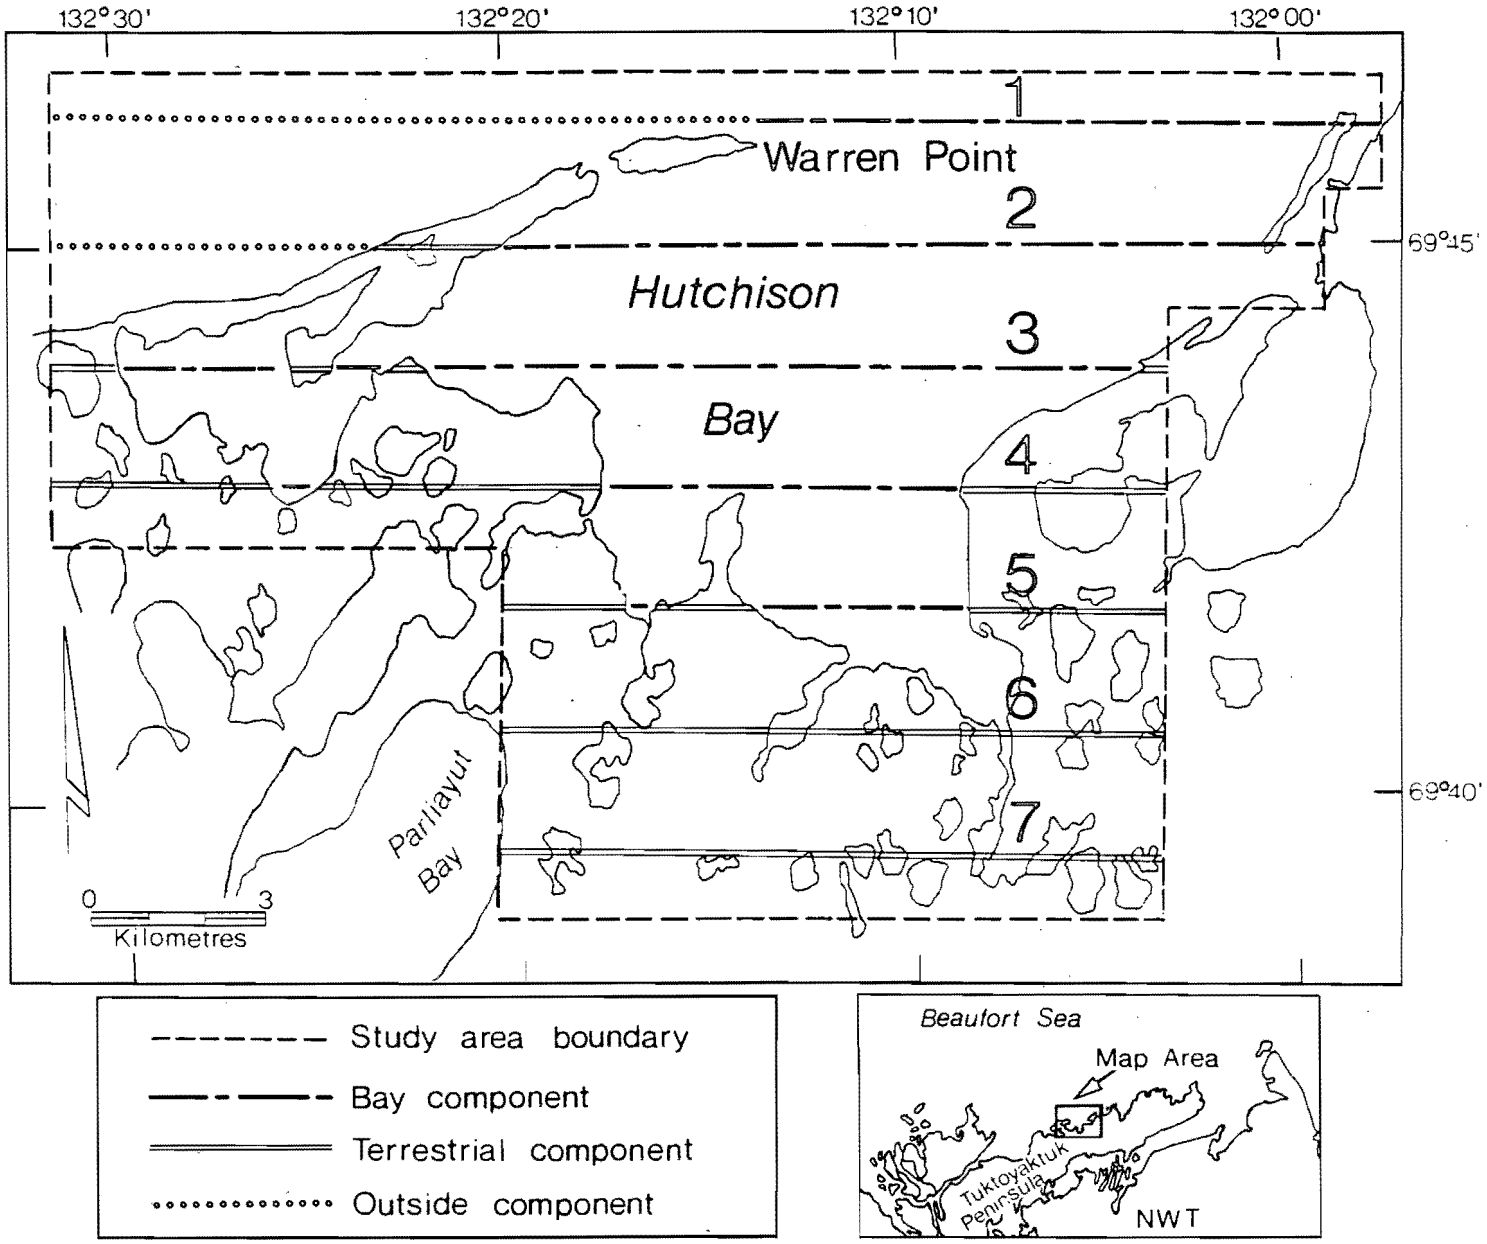

Figure 2. Aerial transects flown at Hutchison Bay on August 5 and 7, 1991, showing the bay, terrestrial and outside components of the study area.

Table 1. Aerial survey coverage of designated components of the McKinley Bay and Hutchison Bay study areas.

Component	McKinley Bay		Hutchison Bay	
	Total area (km^2)	Area surveyed (km^2)	Total area (km^2)	Area surveyed (km^2)
Bay	108.5	19.6	100.5	17.8
Terrestrial	158.5	28.3	91.0	16.3
Outside	39.0	7.1	30.5	5.8
TOTAL	306.0	55.0	222.0	39.9

2.2 Analysis of Data

At both bays, anywhere from 1 to 41% of the diving ducks were not identified to species, depending on such factors as flock size and survey conditions. To avoid underestimating species densities and population estimates on the bay component, it was necessary to include all observations of diving ducks in calculations of these parameters. Thus, for each of the major species, the adjusted number of birds was calculated by multiplying the observed proportion of that species among the identified diving ducks by the total number of diving ducks on all transects.

The mean densities for each species were then calculated by the standard ratio estimator, or the adjusted number of birds on all transects divided by the total area surveyed. Population estimates were found by multiplying the estimated mean density of birds by the total area of the study component (Table 1). The standard error of the population estimate for total diving ducks was calculated using the method by Kingsley and Smith (1980). This equation is described in earlier reports (Cornish et al. 1991).

Numbers of Oldsquaw, scoters and total divers in 1990 and 1991 were compared to values from the initial data set collected from 1981 to 1985 by calculating the t statistic (Steel and Torrie 1980). The mean for each data set was calculated using the adjusted numbers of Oldsquaw, scoters and total divers. The formula for comparison of two sample means where $n_1 \neq n_2$, is as follows:

$$t = \frac{\bar{Y}_1 - \bar{Y}_2}{S_{(\bar{Y}_1 - \bar{Y}_2)}}$$

where:

$\bar{Y}_1$ = the mean of adjusted numbers of diving ducks observed from 1981 to 1985 (for Hutchison Bay, from 1982 to 1985)

$\bar{Y}_2$ = the mean of adjusted numbers of diving ducks observed at each bay from 1990 to 1991

$$S_{(\bar{Y}_1 - \bar{Y}_2)} = \sqrt{\frac{s^2 (n_1 + n_2)}{n_1 (n_2)}}$$

and

$$s^2 = \text{pooled variance} = \frac{(n_1 - 1) S_1^2 + (n_2 - 1) S_2^2}{(n_1 - 1) + (n_2 - 1)}$$

n_1 = first sample size, which was 5 years for McKinley Bay (1981 to 1985) and 4 years for Hutchison Bay (1982 to 1985)

n_2 = second sample size, which was 2 years for both bays (1990, 1991)

For each year, only the results from the survey with the best weather and sea conditions were included for data comparisons. Significant differences were accepted at $p < 0.05$.

3.0 RESULTS

3.1 Survey Conditions

Aerial surveys in 1991 were conducted on August 5 and August 7. The first survey commenced at Hutchison Bay on August 5. During this survey, conducted between 1000 and 1115 hours, there was 90% cloud and no precipitation. However, light to moderate winds from the southwest created moderate waves with occasional whitecaps, reducing visibility of birds on the water. Overall survey conditions were rated as only fair to good.

Survey conditions for the second survey at Hutchison Bay, conducted from 1250 to 1353 on August 7, were rated as good to excellent. Skies were overcast, so there was no glare, and winds were very light, creating nearly calm sea conditions. Light intermittent rain showers occurred occasionally during the survey but were not considered to have affected visibility of birds.

Because of the wind, McKinley Bay was not surveyed on August 5. Instead, two surveys were carried out at McKinley Bay on August 7. The first survey at McKinley Bay was conducted from 1015 to 1142 hours. Sea conditions were relatively calm, with small waves but no whitecaps and only light winds from the southeast. However, skies were overcast, and occasional rain sometimes reduced visibility for surveying. During the second survey at McKinley Bay, conducted between 1530 and 1715, survey conditions were rated as good to excellent. Winds were very light, cloud cover was 100%, little precipitation was reported, and sea conditions were nearly calm. This survey was rated the best of the two surveys at McKinley Bay.

3.2 Abundance of Birds

The results of the 1991 surveys are presented in detail in Appendices C and D.

3.2.1 Bay Component

3.2.1.1 Diving Ducks

Total numbers and densities of birds on the bay components of McKinley Bay and Hutchison Bay are presented in Tables 2 and 3, respectively. Over 90% of birds at both bays were diving ducks, with the exception of the August 5 survey at Hutchison Bay when 83% were divers. Densities of divers at McKinley Bay far exceeded densities at Hutchison Bay. Comparing the results of the surveys with the best conditions, McKinley Bay had a density of 291 diving ducks/km^2, whereas there were only 111 birds/km^2 at Hutchison Bay (Tables 2 and 3).

Table 4 gives the species composition of diving ducks at each bay during the best survey in 1991. About 96% of identified diving ducks at McKinley Bay were Oldsquaw or scoters. However, these two species represented only 77% of diving ducks identified at Hutchison Bay. Also, the relative proportions of the two major species differed between bays. At McKinley Bay, there were twice as many Oldsquaw as scoters, whereas at Hutchison Bay, Oldsquaw and scoters were seen in about equal proportions (Table 4). Two species of scoters were recorded: Surf

Table 2. Number and density of birds observed on the bay component at McKinley Bay, August 7, 1991[a].

	First survey		Second survey

[a] Second survey.

[b] $\frac{\text{Number observed}}{\text{Identified diving ducks}}$ X Total diving ducks

[c] Includes unidentified scoters.

Scoters and White-winged Scoters, but the latter species was found in very low numbers, and only at Hutchison Bay.

Red-breasted Mergansers formed a major component of the diving duck population at Hutchison Bay, representing 15% of the total count. Scaup were seen in small numbers in both bays; however, the greatest numbers of scaup were seen at Hutchison Bay, where they represented 7% of diving ducks. Eiders, seen in low numbers in previous years, were not recorded during the 1991 surveys.

Forty-one percent of the divers counted at McKinley Bay could not be identified to species or genus; 26% of divers at Hutchison Bay were unidentified. Numbers of each species, extrapolated to include the unidentified diving ducks, are presented in Table 4.

Population estimates of the diving duck species, using adjusted numbers of birds on the bay component during the best survey, are given in Table 5. The estimated population of diving ducks in McKinley Bay on August 7, 1991, based on data from the second survey, was 31 592 ± 7953. At Hutchison Bay, the total population of diving ducks was estimated to be 11 111 ± 771 birds on August 7.

Comparisons of the data from the two series of aerial surveys are summarized in Figure 3, and Tables 6 and 7. At McKinley Bay, the mean number of divers observed in more recent years (1990 and 1991) was significantly greater ($p<0.05$) than the mean number observed during the earlier set of surveys, from 1981 to 1985 (Table 6). Most of the increase in total divers was due to significantly greater numbers of Oldsquaw ($p<0.05$) in 1990-91 than in the years 1981 to 1985. No significant change in total numbers of diving ducks or individual species numbers was detected at Hutchison Bay between the two series of surveys (Table 7). Adjusted numbers of each species counted in all years of surveys are presented in Appendix E.

The results of the 1991 surveys were not consistent with the 1990 results. In 1990, at both McKinley Bay and Hutchison Bay, there was a significant increase in numbers of Oldsquaw and scoters compared to results from 1981 to 1985. However, in 1991, significant increases in diving duck numbers, compared to the earlier set of surveys, were recorded only at McKinley Bay. Thus, while diving duck numbers at McKinley Bay in 1991 remained similar to numbers recorded in 1990, at Hutchison Bay, numbers of diving ducks in 1991 declined to less than half of what they were in 1990 (Fig. 3).

3.2.1.2 Other Species

Observers frequently recorded loons on the bays in 1991, in average densities of about $1/km^2$ at each bay (Tables 2 and 3). Two species of loons were identified: Red-throated Loons (88% of recorded observations) and Pacific Loons (Appendices C and D). Other species encountered on the bays, mostly near the lagoons and on the spits, were the Greater White-fronted Goose, Tundra Swan, Glaucous Gull, Northern Pintail, Arctic Tern, Parasitic Jaeger and shorebirds.

Table 5. Population estimates of the diving ducks on the bay component at McKinley Bay and Hutchison Bay on August 7, 1991.

Species	Location	Adjusted number[a]	Density (birds/km^2)	Population estimate

3.2.2 Terrestrial Component

The numbers and densities of birds recorded on the terrestrial components in 1991 are listed in Tables 8 and 9 for McKinley Bay and Hutchison Bay, respectively. As on the bay component, diving ducks were the most abundant birds recorded on the terrestrial component. At McKinley Bay, diving ducks were found in densities ranging from 27 to 44 birds/km^2 (Table 8). At Hutchison Bay, diving duck densities of 7 to 12 birds/km^2 were observed (Table 9).

The most common diving ducks on the McKinley Bay terrestrial component were Oldsquaw; about 86% of identified divers counted over the two days belonged to this species (Appendix C). At Hutchison Bay, scaup represented about 75% of identified diving ducks on the terrestrial component over the two days, while an average of 10% were Oldsquaw (Appendix D). Red-breasted Mergansers were also recorded at both bays, but were more common at McKinley Bay.

Both Red-throated and Pacific loons were recorded on the lakes and ponds, but their relative numbers varied between the two study areas. At McKinley Bay, Red-throated Loons outnumbered Pacific Loons by 3:1, whereas Pacific occurred more often than Red-throated loons at Hutchison Bay.

Two species of geese were recorded on the terrestrial component, but Greater White-fronted Geese outnumbered Brant by a ratio of at least 4:1 at both bays (Appendices C and D). The greatest density of dabbling ducks observed in 1991 was 17 birds/km^2, recorded during the second survey on August 7 at McKinley Bay (Table 8). Most dabblers were Northern Pintail, although American Wigeon were also recorded.

Tables 10 and 11 show average numbers of birds observed on the terrestrial component at McKinley Bay and Hutchison Bay, during the two series of surveys, 1990-91 and 1981-85. On average, 3 to 4 times more diving ducks were observed at both bays in 1990-1991 than from 1981 to 1985. Numbers of Oldsquaw at McKinley Bay in particular were substantially higher in 1990-1991. At Hutchison Bay, most of the increase in numbers of divers on the terrestrial component was due to higher numbers of scaup. Other species which showed increases at McKinley Bay in 1990 and 1991 include Pacific Loons, Red-throated Loons, Tundra Swans, Northern Pintail, and American Wigeon (Table 10). At Hutchison Bay, Tundra Swans and Greater White-fronted Geese were seen more frequently in 1990-1991 than in the earlier series of surveys (Table 11).

When results from both bay and terrestrial components (the two largest components of the study area) are combined, it is apparent that greater numbers of diving ducks were observed on the McKinley Bay study area in 1991 than in all other years of surveys (Appendix F). However, on the Hutchison Bay study area, overall numbers of diving ducks were lower in 1991 than in any other year except 1985 (when ice remained in the bay in early August).

3.2.3 Outside Component

Diving ducks, geese, loons, gulls and terns were recorded, in small numbers, on the outside component (Appendices C and D). Overall densities of diving ducks were much lower on the outside component (up to 5 birds/km^2 at McKinley Bay and a maximum of 20 birds/km^2 at Hutchison Bay), than within the bays.

No geese were recorded outside of Hutchison Bay, but at McKinley Bay, a total of 55 geese (two groups of 25 dark geese and one group of 5 Brant) were found on the outside component. Red-throated Loons, and, less commonly, Pacific Loons were consistently recorded in low numbers on the outside components.

3.3 Distribution of Birds

3.3.1 McKinley Bay

The distribution of selected waterfowl groups observed during the two aerial surveys at McKinley Bay on August 7, 1991, is presented in Figures 4 and 5. Isolated groups of less than 10 diving ducks are not illustrated.

Diving Ducks

During the first survey on August 7, few large concentrations of diving ducks were observed, whereas on the second survey a large proportion were densely grouped into large flocks. Diving ducks seemed to favour three areas: north of the artificial island; near the long narrow spit at the east end of the bay; and at the south end of the bay (Figs. 4 and 5).

On the terrestrial component, diving ducks were distributed on the larger lakes south of McKinley Bay, and on the lagoon system entering the south end of the bay. Most divers identified in the terrestrial areas were Oldsquaw, scaup or mergansers; scoters were rare on the terrestrial component. A large concentration of 820 Oldsquaw was observed on a lake west of the lagoon system, on the second survey. Large flocks of divers also occurred on other lakes southwest of the bay (Figs. 4 and 5).

Red-breasted Mergansers and scaup were observed on both bay and terrestrial areas. On the bay, these species were usually observed close to shore. Bay areas most frequently utilized by these species included: a long, narrow spit at the east side of the bay; the extreme south end of the bay; the western shoreline areas; and the area south of Atkinson Point. Both species were also observed in shallow areas near shore on the outside component, most frequently in the protected bay on the west side of the study area. Red-breasted Mergansers favoured the shallow lagoon areas south of the study area. Scaup were observed on tundra ponds and lakes, and often mixed with Oldsquaw in these areas.

Other Species

Several sections of the McKinley Bay study area were utilized by geese (Figs. 4 and 5). In terms of numbers of observations, in 1991 the most important areas for geese were the following: Louth Bay; the lagoon system at the south end of

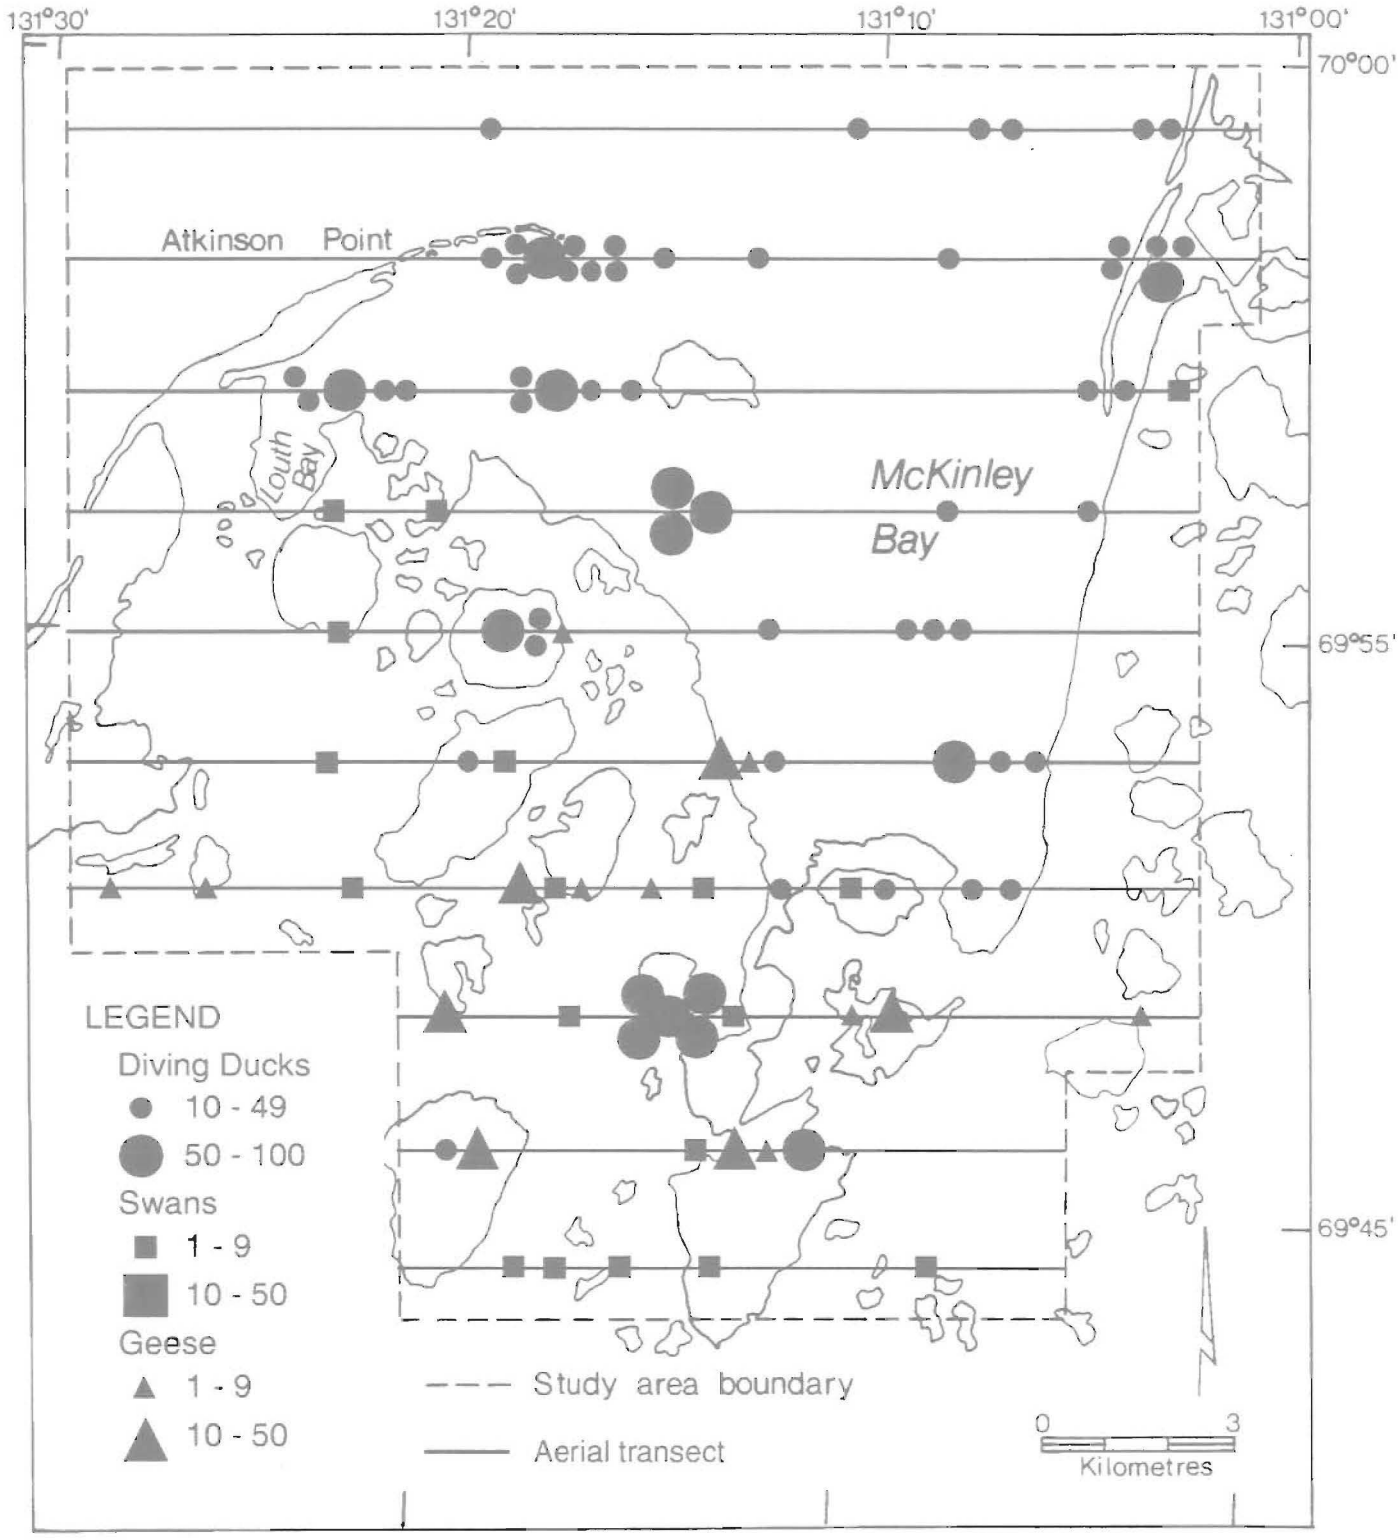

Figure 4. Distribution of waterfowl observed during the first aerial survey at McKinley Bay on August 7, 1991.

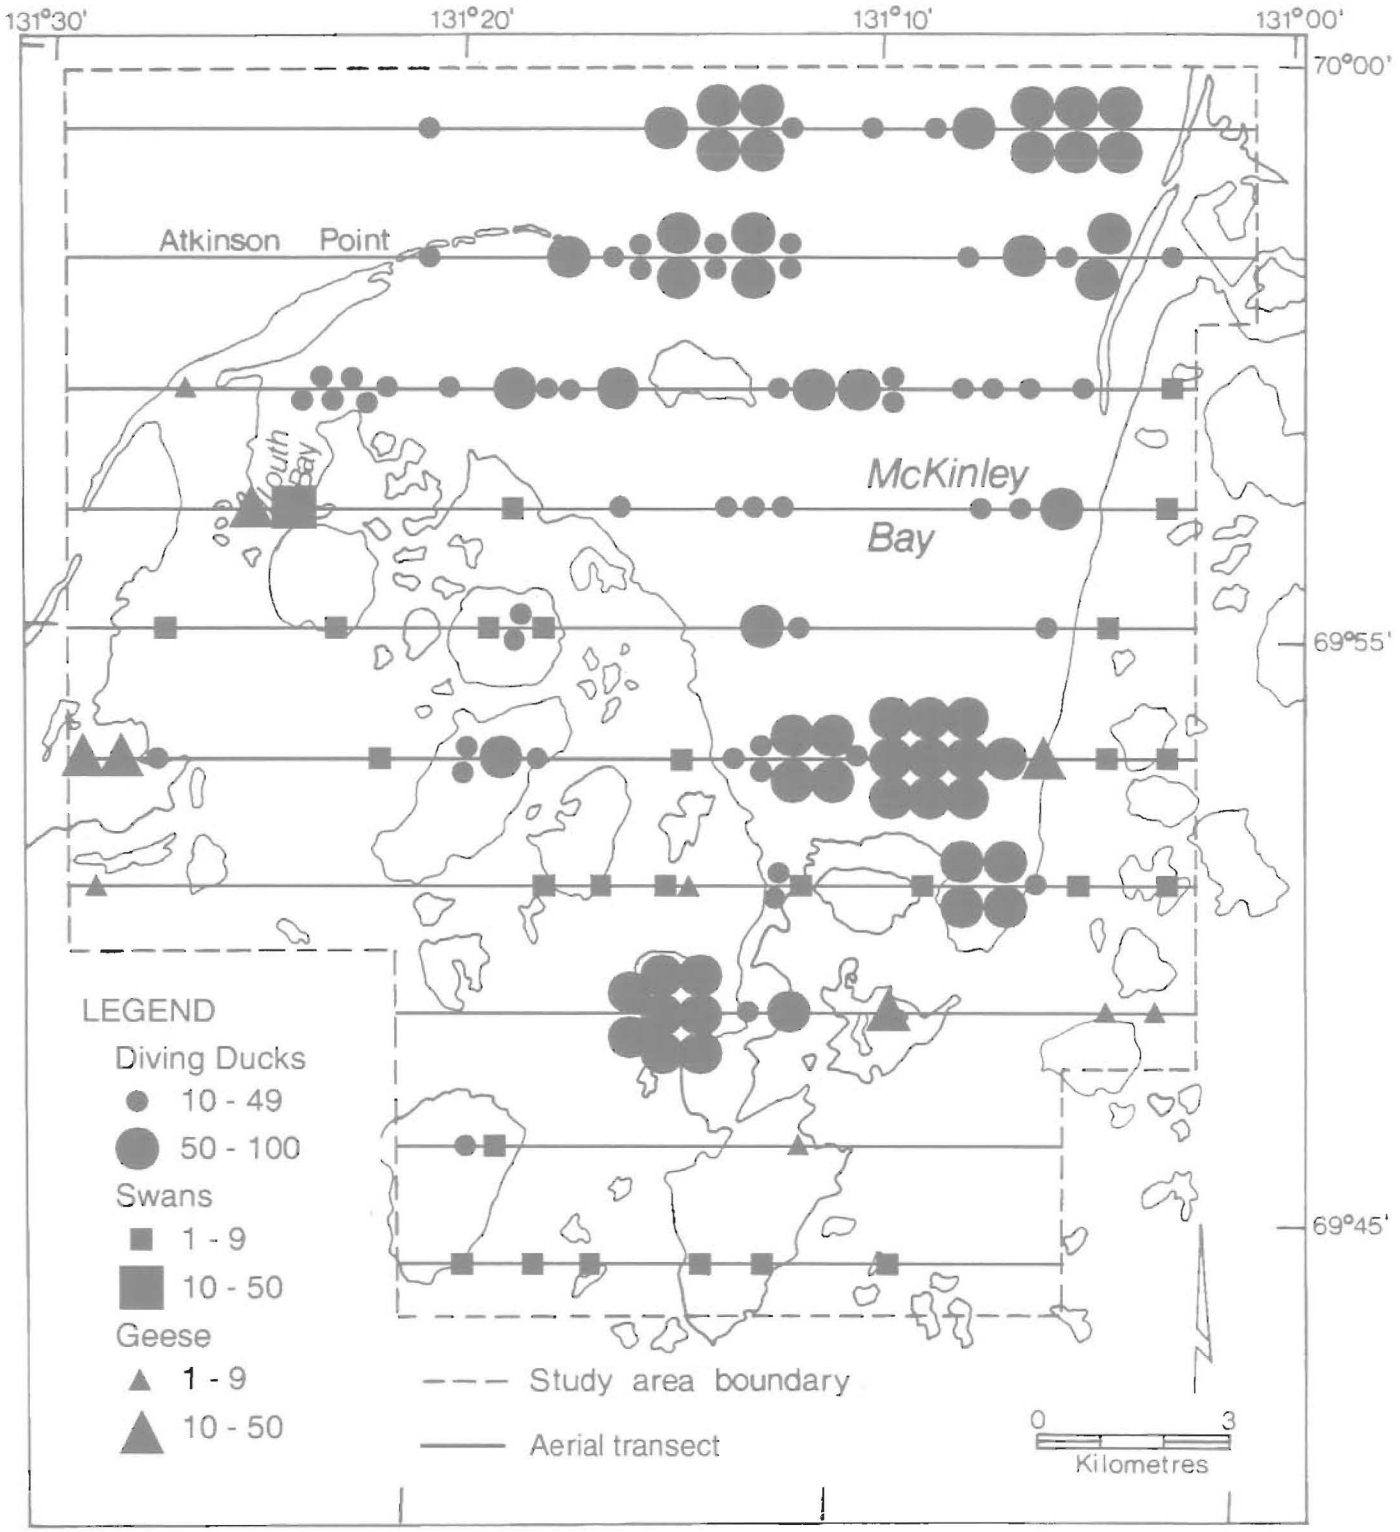

Figure 5. Distribution of waterfowl observed during the second aerial survey at McKinley Bay on August 7, 1991.

McKinley Bay; tundra lakes southwest of McKinley Bay; and the protected bay on the outside component west of McKinley Bay. Geese were also commonly observed in these areas in previous surveys from 1981 to 1985, and in 1990.

Tundra Swans were fairly evenly distributed in pairs and family groups, over the entire terrestrial component. They were seen on lakes, ponds and the shallow lagoon system. One large group consisting of 12 non-breeding adult swans was seen at the south end of Louth Bay during the second survey (Fig. 5).

Dabbling ducks, most of which were Northern Pintails, were distributed on tundra ponds and lakes throughout the study area, but were especially abundant southwest of McKinley Bay. Small numbers also occurred on lagoon channels and tidal mudflats. A flock of 55 American Wigeon was noted on Louth Bay.

Glaucous Gull were most common on Atkinson Point, on Louth Bay, and near a spit at the northeast corner of the bay. When terrestrial surveys were carried out in 1982, scattered nests of Glaucous Gulls were found in the low gravel areas on Atkinson Point, and on tundra ponds in the vicinity of Atkinson Point. In 1991, as in previous years, gulls were also encountered frequently on tundra lakes and ponds.

The greatest numbers of shorebirds were observed on tidal marshes, especially near Louth Bay and south of McKinley Bay. Sandhill Cranes were distributed throughout the terrestrial areas, and were recorded as individuals, in pairs or occasionally with young.

3.3.2 Hutchison Bay

Figures 6 and 7 show the distribution of selected waterfowl groups during aerial surveys at Hutchison Bay on August 5 and 7, respectively.

Diving Ducks

The distribution of Oldsquaw and scoters varied between the two days of surveys. On August 5, they were fairly evenly distributed, in small flocks, across most of Hutchison Bay (Fig. 6). The lowest density was in the middle of the bay. Most Oldsquaw and scoters recorded during the August 7 survey at Hutchison Bay were in the western sections of the bay, close to Warren Point, or at the south end of the bay (Fig. 7). No consistent differences in patterns of distribution of Oldsquaw and scoters within the bay were noted.

During both surveys, Red-breasted Mergansers and scaup were found in areas close to shore. Scaup favoured the western arm of the bay, southwest of Warren Point. Mergansers were observed primarily in three areas: just off the northeast tip of Warren Point, south of Warren Point (where a large flock of 190 was recorded on August 7), and also off the tip of a peninsula jutting into the southwest section of the bay.

In contrast to McKinley Bay, relatively few divers were recorded in Hutchison Bay terrestrial areas (Figs. 6 and 7). Small groups of divers occurred on lakes or lagoon areas. A flock of 75 scaup was observed on a sheltered brackish bay east

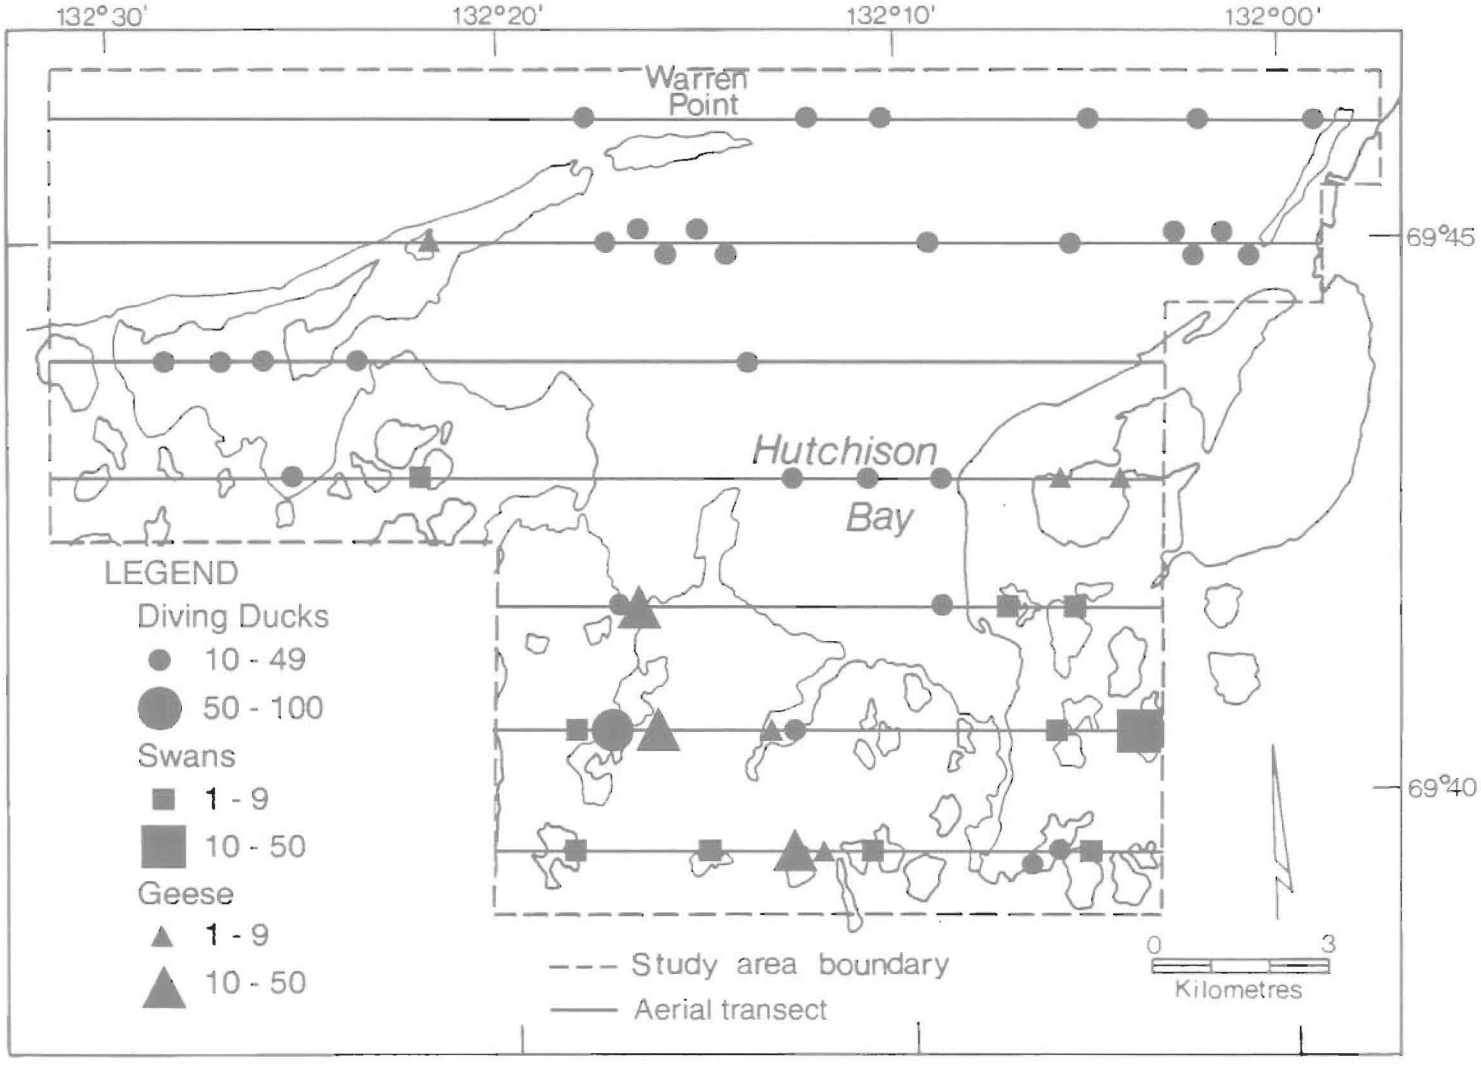

Figure 6. Distribution of waterfowl observed during the aerial survey at Hutchison Bay on August 5, 1991.

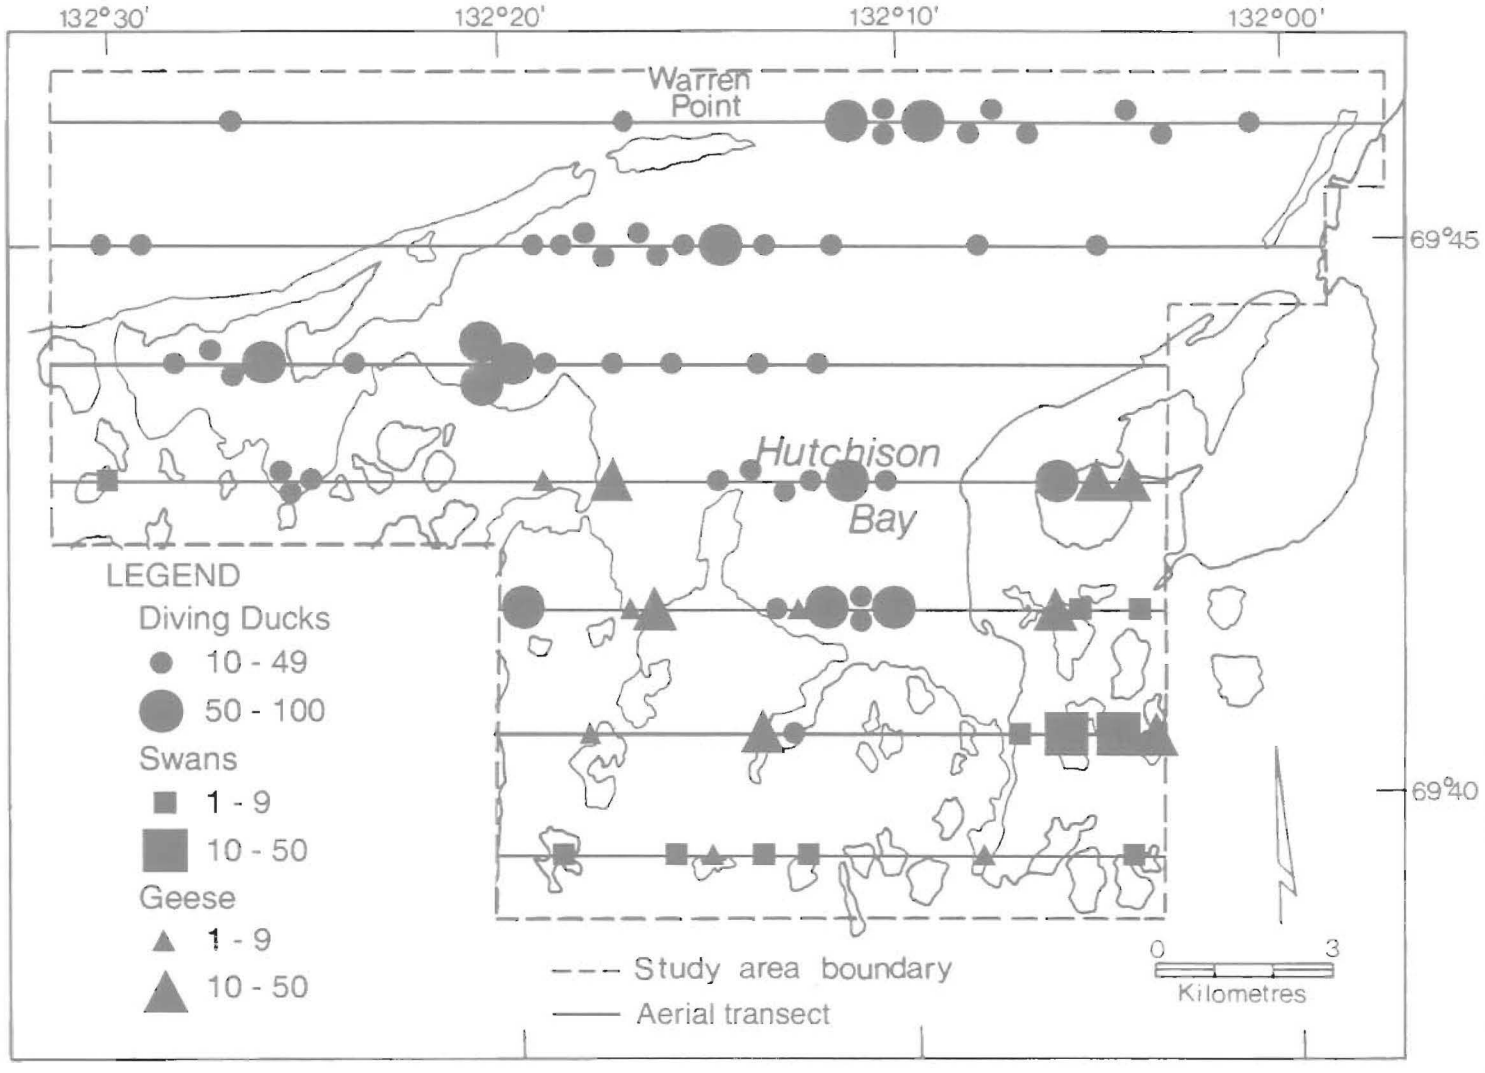

Figure 7. Distribution of waterfowl observed during the aerial survey at Hutchison Bay on August 7, 1991.

of Hutchison Bay; observers also noted 700 unidentified divers off transect in the same area.

Other Species

Geese were observed primarily on tidal flats in the more sheltered areas of Hutchison Bay, and on tundra lakes. Areas important to geese included a little bay west of a peninsula jutting into the southwest section of Hutchison Bay (a total of 50 Greater White-fronted Geese were counted there on August 7); a sheltered bay east of Hutchison Bay; several lakes, especially east of the bay; and the long narrow lagoon channels (Figs. 6 and 7).

Tundra Swans were distributed on lakes and ponds, especially at the south end of the study area, as well as on shallow lagoon channels of the bay. Two large groups of swans (22 swans in the largest group) were noted on a lake east of the bay.

Dabbling ducks occupied the ponds and shallow lakes throughout the study area, but large numbers were concentrated east of Hutchison Bay, and in the small embayment west of the peninsula jutting into the southwest section of Hutchison Bay.

Gulls were frequently encountered throughout the study area. Large numbers of gulls occurred near Warren Point spit, and on a spit in the northeast section of the bay.

Shorebirds were noted occasionally in small groups close to the shoreline. The largest numbers were near Warren Point. A group of 40 phalaropes occurred in the small bay in the southwest section of Hutchison Bay. Small numbers of Sandhill Cranes were recorded occasionally, on the tundra south of Hutchison Bay.

3.4 Flock Size

Table 12 shows the distribution of diving ducks in flocks of different sizes, based on data from the August 7, 1991 surveys at McKinley Bay and Hutchison Bay. The distribution of diving ducks in different flock sizes varied between the two bays.

At McKinley Bay, almost 50% of all divers observed were in flocks of 100 or more birds. At Hutchison Bay, most birds (68%) were in small flocks of less than 50 birds and there were no large flocks greater than 200 birds.

Among identified divers only, at McKinley Bay, there were slightly more Oldsquaw than scoters in large flocks of 100 or more birds. However, at Hutchison Bay, there was little apparent difference in the distribution of the two major diving duck species in flocks of various sizes. Over 80% of identified Oldsquaw and 75% of scoters were in small flocks of less than 50 birds at Hutchison Bay.

Table 12. Distribution of diving ducks in flocks of different sizes on the bay component at McKinley Bay and Hutchison Bay, August 7, 1991.

4.0 DISCUSSION

The results of these aerial surveys are reasonable estimators of trends in populations of diving ducks using McKinley Bay and Hutchison Bay. Survey techniques were consistent throughout all years of the study, survey conditions (cloud cover and wind speed) were similar each year, observers were currently experienced, and the same observers were used for all surveys (with the exception of one observer in 1981).

Throughout the period covered by the study (1981 to 1991), some fairly consistent patterns of diving duck abundance on the bay components of each study area are apparent. Although absolute numbers of individual species of divers using McKinley Bay and Hutchison Bay varied from year to year, the relative numbers of diving ducks using the bays appeared to be correlated. In all years of surveys except 1991, slightly greater numbers of diving ducks were recorded on the bay component at Hutchison Bay than at McKinley Bay.

Similar observations were made in another Beaufort Sea bird study. Between 1979 and 1982 at Simpson Lagoon, Oldsquaw densities showed much variation from year to year (Johnson and Richardson 1981). However, relative densities of Oldsquaw at Simpson Lagoon, compared to Oldsquaw densities at nearby Stump Island Lagoon, remained fairly constant (Troy et al. 1983, in Houghton et al. 1984).

It is unknown why there were so few diving ducks at Hutchison Bay in 1991. Lower diving duck numbers may reflect: 1) human disturbance, 2) local changes in feeding conditions for the diving ducks in Hutchison Bay and surrounding areas, 3) ice remaining in the bay when ducks arrive for the moult, or 4) a chance shift in distribution of diving ducks locally in Hutchison Bay and surrounding areas.

No known human disturbances occurred in Hutchison Bay during the period immediately prior to the 1991 surveys. Past experience at McKinley Bay indicates that it would require a considerable amount of disturbance to drive moulting diving ducks away from the bay for more than a few days (Cornish and Allen 1983; Sharp 1978). In 1982, we repeatedly surveyed McKinley Bay by zodiac boat with no apparent effect on the number of ducks moulting in the bay. In an effort to develop a technique for scaring moulting ducks away from oil spills, Sharp (1978) tried to drive ducks away from Atkinson Point, using two types of noise-makers. Although the noise-makers were effective in deterring the birds from the area initially, habituation occurred within about 3 days. Thus, human disturbance is not likely why there were so few birds in Hutchison Bay compared to McKinley Bay in 1991.

McKinley Bay and Hutchison Bay are similar in size, and only about 45 km from each other. Most natural oscillations in physical variables (such as ice dynamics and other climate-controlled variables), or biological variables (such as invertebrate prey densities) at Hutchison Bay should correspondingly have affected bird numbers at McKinley Bay. For example, large expanses of ice remained in both McKinley Bay and Hutchison Bay in early August 1985. The resulting impact on diving duck numbers, compared to previous years when there was no ice in early August, was similar at the two bays. Significantly fewer diving ducks utilized both bays in August 1985, but relative numbers of divers at the two bays remained the same.

Due to the proximity of prime moulting habitat near Hutchison Bay, there may in some years be a chance shift of moulting diving ducks from Hutchison Bay to surrounding areas. Large areas of habitat suitable for moulting diving ducks (shallow protected bays providing high prey densities, loafing sites and shelter from wind and waves; Salomonsen 1968) exist within a kilometre of the Hutchison Bay study area (Alexander et al 1988). These areas occur on both sides of Hutchison Bay: Parliayut Bay to the west, and a large sheltered embayment to the east. McKinley Bay on the other hand is more isolated, with no adjacent large areas of similar habitat suitable for moulting diving ducks.

No intensive annual systematic surveys have been carried out in the bays adjacent to Hutchison Bay. However, data from other studies suggest that both areas are heavily used by diving ducks, especially Oldsquaw (40 to 60 birds/km^2), scaup (up to 174 birds/km^2) and scoters (10 to 31 birds/km^2) (Alexander 1986, Barry et al. 1981, Barry and Barry 1982, Dickson et al. 1983; in Alexander et al. 1988).

How diving ducks are distributed within Hutchison Bay and adjacent areas may vary from year to year. In 1991, for example, large numbers of diving ducks may have utilized Parliayut Bay in early August, instead of Hutchison Bay. In order to determine if this is happening each year, the area surveyed at Hutchison Bay should be expanded to include the two adjacent bays.

In summary, the 1991 surveys provide further evidence that the population of diving ducks utilizing McKinley Bay in recent years (1990 - 1991) has increased since our earlier surveys from 1981 to 1985. However, results from surveys in 1991 at Hutchison Bay contradict the 1990 data, and are not conclusive. Because of the variability in densities of diving ducks recorded in 1990 and 1991 at Hutchison Bay, it is recommended that another year of aerial surveys be carried out.

APPENDIX A. INDUSTRIAL ACTIVITY IN MCKINLEY BAY

Development and use of McKinley Bay as a Winter Harbour

An entrance channel and mooring basin were dredged in the northeast section of McKinley Bay in September of 1979. This was followed in 1980 by construction of a more sheltered mooring area, southwest of the original location. An artificial island was created to the north of the new location with the dredged spoils, to further protect the moored ships from storms and ice movement. In 1981, docking facilities were constructed, and the artificial island and mooring basin were expanded. In 1982 and 1983, an airstrip and accommodation for 130 people were put on the island. The island also became a storage area for fuel and materials to support the offshore drilling operation.

Use of McKinley Bay as a harbour peaked from 1982 to 1985. Since then there has been very little offshore drilling activity in the Canadian Beaufort Sea. Appendix A1 summarizes the activities associated with industrial use of McKinley Bay from 1979 to 1991.

Most of the oil spills at McKinley Bay occurred between 1979 and 1984 (Appendix A2). The two largest spills which were 500 gal in 1980 and 1100 gal in 1982 both occurred after freeze-up. There was another large spill of 7000 gal at Atkinson Point in February in 1983, but the oil did not enter the water. Since 1985, there have been only two small spills of less than 25 gal within McKinley Bay.

Two oil spill clean-up experiments were permitted in McKinley Bay under the Ocean Dumping Control Act (Seakem Group Ltd. 1991). The first experiment involved dumping about 4000 gal of crude oil under the ice in three releases from December, 1979 to April, 1980. In the second experiment which occurred in February, 1982, about 75 gal of emulsified crude oil were released under the ice.

There have been no oil spills in Hutchison Bay from 1979 to present.

Appendix A1. Level of industrial activity at McKinley Bay, 1979-1991.

Year	Dredging activity(m^3)[1]	No. of ships in January[2]	No. of ships mobilized[2]	Annual no. of person-days[3]	No. of flights	No. of offshore drilling operations[5]

[1]Data from NWT Spill Reports, Government of NWT.
No oil spills occurred in Hutchison Bay from 1979 to 1991.
Spill of 6995 gal of fuel oil on land at Atkinson Point on 9 February, 1983 and two spills <1 gal at McKinley Bay not included in above.

Appendix B. Scientific names of species of birds observed at McKinley Bay and Hutchison Bay.

Common name	Scientific name
Red-throated Loon	*Gavia stellata*
Pacific Loon	*Gavia pacifica*
Common Loon	*Gavia immer*
Tundra Swan	*Cygnus columbianus*
Greater White-fronted Goose	*Anser albifrons*
Brant	*Branta bernicla*
Canada Goose	*Branta canadensis*
Snow Goose	*Chen caerulescens*
Mallard	*Anas platyrhynchos*
Northern Pintail	*Anas acuta*
American Wigeon	*Anas americana*
Canvasback	*Aythya valisineria*
Scaup sp.	*Aythya sp.*
King Eider	*Somateria spectabilis*
Common Eider	*Somateria mollissima*
Oldsquaw	*Clangula hyemalis*
Surf Scoter	*Melanitta perspicillata*
White-winged Scoter	*Melanitta fusca*
Red-breasted Merganser	*Mergus serrator*
Northern Harrier	*Circus cyaneus*
Rough-legged Hawk	*Buteo lagopus*
Gyrfalcon	*Falco rusticolus*
Willow Ptarmigan	*Lagopus lagopus*
Ptarmigan sp.	*Lagopus sp.*
Sandhill Crane	*Grus canadensis*
Whimbrel	*Numenius phaeopus*
Stilt Sandpiper	*Calidris himantopus*
Red-necked Phalarope	*Phalaropus lobatus*
Phalarope sp.	*Phalaropus sp.*
Pectoral Sandpiper	*Calidris melanotos*
Parasitic Jaeger	*Stercorarius parasiticus*
Jaeger sp.	*Stercorarius sp.*
Glaucous Gull	*Larus hyperboreus*
Sabine's Gull	*Xema sabini*
Arctic Tern	*Sterna paradisaea*
Short-eared Owl	*Asio flammeus*
Common Raven	*Corvus corax*

Appendix C1. Birds observed on the bay component of the first set of aerial surveys at McKinely Bay on August 7, 1991[a].
