## TECHNICAL REPORT SERIES CANADIAN WILDLIFE SERVICE

This series of reports, established in 1986, contains technical and scientific information from projects of the Canadian Wildlife Service. The reports are intended to make available material that either is of interest to a limited audience or is too extensive to be accommodated in scientific journals or in existing CWS series.

Demand for these Technical Reports is usually confined to specialists in the fields concerned. Consequently, they are produced regionally and in small quantities; they can be obtained only from the address given on the back of the title page. However, they are numbered nationally. The recommended citation appears on the title page.

Technical Reports are available in CW.S libraries and are listed in the catalogue of the National Library of Canada in scientific libraries across Canada. They are printed in the official language chosen by the author to meet the language preference of the likely audience, with a résumé in the second official language. To determine whether there is a significant demand for making the reports available in the second official language, CWS invites users to specify their official language preference. Requests for Technical Reports in the second official language should be sent to the address on the back of the title page.

## SÉRIE DE RAPPORTS TECHNIQUES DU SERVICE CANADIEN DE LA FAUNE

Cette série de rapports donnant des informations scientifiques et techniques sur les projets du Service canadien de la faune (SCF) a démarré en 1986. L'objet de ces rapports est de promouvoir la diffusion d'études s'adressant à un public restreint ou trop volumineuses pour paraître dans une revue scientifique ou l'une des séries du SCF.

Ordinairement, seuls les spécialistes des sujets traités demandent ces rapports techniques. Ces documents ne sont donc produits qu'à l'échelon régional et en quantités linitées; ils ne peuvent être obtenus qu'à l'adresse figurant au dos de la page titre. Cependant, leur numérotage est effectué à l'échelle nationale. La citation recommandée apparaît à la page titre.

Ces rapports se trouvent dans les bibliothèques du SCF et figurent aussi dans la liste de la Bibliothèque nationale du Canada utilisée dans les principales bibliothèques scientifiques du Canada. Ils sont publiés dans la langue officielle choisie par l'auteur en fonction du public visé, avec un résumé dans la deuxième langue officielle. En vue de déterminer si la demande est suffisamment importante pour produire ces rapports dans la deuxième langue officielle, le SCF invite les usagers à lui indiquer leur langue officielle préferée. Il faut envoyer les demandes de rapports techniques dans la deuxième langue officielle à l'adresse indiquée au verso de la page titre.

#### Abstract

The Little Qualicum River estuary consists of intertidal and estuarine habitats with sandspit, upland meadow, hedgerow and mature second growth mixed-forest. It is situated on the east coast of Vancouver Island and enters the Strait of Georgia. To determine the abundance and distribution of migratory and resident birds in the Little Qualicum River estuary, regular surveys were conducted weekly or biweekly from 19 January 1975 to 25 May 1979.

The number of bird species recorded using the study site over the study period was 173. This number includes 68 species of passerines, 28 species of waterfowl, 19 species of shorebirds, 11 species of raptors and 10 species in the gull family.

The study area supported a minimum of 37,271 birds in at least one stage of their life history during the 4.5 year study period.

Most of the birds counted using the area during the study were observed in spring. Spring numbers were dominated by gulls and waterfowl; the passerines ranked a distant third. In summer, bird use of the study area was at its lowest. Passerines were consistently about half of all the birds counted in summer and the gulls were about one quarter; in most years the waterfowl ranked third. The highest user group in autumn and winter was consistently the waterfowl. Second ranking was most often the gulls or passerines but their proportions often varied from year to year. Over the entire study waterfowl (mostly diving ducks) used the area in the largest numbers, gulls ranked second and passerines a distant third.

An annotated species list discusses arrival and departure dates, highest number seen in one day, habitat use and other details for each of the species. A checklist includes the species seen on the surveys as well as other species recorded on the estuary at other times.

Concluding comments note human impacts particularly from direct disturbance of the birds using the estuary and discuss possibilities for minimizing this disturbance. Suggestions are also made for further study of the avifauna that would complete the picture of bird use of the Little Qualicum River estuary.

## Résumé

L'estuaire de la rivière Little Qualicum consiste en habitats intertidaux et estuariens de même qu'en bancs de sable, alpages, végétation riveraine et peuplements mûrs de seconde venue. Il est situé sur la côte est de l'île de Vancouver et débouche dans le détroit de Georgia. L'étude consistait à déterminer le taux d'abondance et la répartition des populations d'oiseaux migrateurs et d'oiseaux résidents dans l'estuaire, et à procéder pour cela à des relevés hebdomadaires et bimensuels, lesquels ont été effectués entre le 19 janvier 1975 et le 25 mai 1979.

Au cours de la période étudiée, on a enregistré la présence de 173 espèces d'oiseaux. Ce nombre comprenait 68 espèces de passereaux, 28 espèces d'oiseaux aquatiques, 19 espèces d'oiseaux de rivage, 11 espèces d'oiseaux rapaces et 10 espèces de mouettes.

Au cours de la même période ( 4,5 ans), on a observé qu'au moins 37271 oiseaux séjournaient dans l'estuaire à au moins un stade de leur vie.

La plupart des oiseaux recensés dans l'estuaire ont été observés au printemps. Les effectifs printaniers comptaient surtout des mouettes et des oiseaux aquatiques, les passereaux arrivant loin derrière, au troisième rang. C'est en été que les effectifs étaient à leur plus bas, les passereaux comptant pour environ la moitié et les mouettes pour le quart de la population recensée, toutes espèces confondues; et la plupart des années, l'effectif des oiseaux aquatiques était le troisième en importance. Mais en automne et en hiver, c'est invariablement le groupe des oiseaux aquatiques qui était le plus important, le deuxième étant le plus souvent représenté par les mouettes et les passereaux, bien que leur proportion respective variait d'une année à l'autre. Pendant toute la durée de l'étude, on a observé que ce sont les oiseaux aquatiques (pour la plupart des canards plongeurs) qui fréquentaient l'estuaire en plus grand nombre, les mouettes arrivant en second et les passereaux en troisième, loin derrière.

Une liste annotée des espèces indique les dates des arrivées et des départs, le nombre le plus important observé en seul jour, l'usage qui est fait de l'habitat et divers autres renseignements concernant chaque espèce. Une liste de contrôle indique les espèces observées au cours des relevés ainsi que les diverses autres espèces enregistrées dans l'estuaire à d'autres moments.

Dans leur conclusion, les auteurs soulignent l'impact de l'homme sur le milieu, en particulier les perturbations directes qu'il cause sur les oiseaux fréquentant l'estuaire, et ils discutent des moyens d'en minimiser les effets. Ils recommandent également que d'autres études soient menées pour compléter les connaissances sur l'avifaune de l'estuaire de la rivière Little Qualicum.

Michael Dunn, CWS, reviewed the manuscript.

## Introduction

Estuaries along coastal British Columbia are important to a diverse wildlife fauna, particularly resident and migratory birds (Dawe 1976, 1980, Dawe and Lang 1980, Dawe et al. 1994, Butler and Cannings 1989, Butler et al. 1989, Vermeer et al. 1992). This diverse fauna occurs as a result of two major factors: the variety of habitats that meet on these systems and the productivity of those habitats.

Habitats often associated with typical estuarine ecosystems include marine deep water areas, intertidal sand and gravel flats, cobble beaches, mudflats, spits, river and associated riparian habitats, brackish and saline estuarine marshes with their accompanying dendritic channels, and upland grass, forb, and shrub areas that grade to coastal forests.

This concentration of habitats with its accompanying edges and niches supports a tremendous diversity and abundance of wildlife. Inventories from the Little Qualicum River estuary, with an upland area of less than 40 ha, have reported minimums of 14 species of algae, 55 species of fungi, 22 species of bryophytes, 234 species of vascular plants, 29 species of molluscs, 62 families of arthropods, 15 species of fishes, 4 species of amphibians, 4 species of reptiles, 220 species of birds, and 20 species of mammals (Dawe 1976, 1980, unpublished).

Nutrients and sediments brought down from the watersheds by the rivers are deposited on the deltas providing rich substrates and growing conditions for estuarine marsh plants that, along with marine vegetation such as eelgrass (Zostera sp.) and algae, drive the detritus-based estuarine food web. Net primary production of these systems with their attendant marshes and algal beds rival, and in some cases exceed, the production of the tropical rain forests (Ricklefs 1979).

These estuarine ecosystems are important to the survival of both resident and migratory birds. Estuaries act as stepping stones to the millions of birds that migrate along our coast each year providing areas where they can rest and feed during their northern and southern journeys.

In addition, British Columbia's estuaries support Canada's largest wintering populations of waterbirds. Estuaries, in concert with farmlands and freshwater wetlands, form part of a wetlands complex (Eamer 1985) that supports hundreds of thousands of wintering waterbirds. During periods of freezing, however, when farmlands and freshwater marshes are no longer accessible, estuaries become critical habitat to the birds' survival (see Dawe 1980 and Eamer 1985). They are the only ice free areas that have enough food to support the birds over the freezing periods.

In British Columbia, most efforts to document bird-use of estuaries have focused on the larger systems such as the Fraser, Squamish, and Cowichan (Butler and Campbell 1987, Butler and Cannings 1989, Trethewey 1985, Blood et al. 1976); however, the importance of the smaller British Columbia estuaries should
not be overlooked (see Butler et al. 1989). Collectively, these smaller systems contribute significantly to the maintenance of our migratory and resident bird populations.

The Canadian Wildlife Service (CWS) has long recognized the importance of these areas and over the past 15 years has gathered data on the bird use of many of our smaller estuaries. This report documents bird use and numbers on the Little Qualicum River estuary, British Columbia over the period 19 January 1975 through 1 February 1979.

In addition, data collected by the CWS as well as observations by other naturalists have been included in this report. The results will be of interest to both the wildlife manager and the birdwatching public who want to know more about the avifauna of the Little Qualicum River estuary.

## The Study Area

The Little Qualicum River estuary ( $49^{\circ} 22^{\prime} \mathrm{N}, 124^{\circ} 29^{\prime} \mathrm{W}$ ) is situated on the east coast of Vancouver Island approximately 5 km west of Qualicum Beach, British Columbia (Figure 1). The surficial geology of the study area is primarily marine and fluvial deltaic deposits. The channel and flood plain deposits on the delta consist largely of sands and gravels, although parts may be surfaced by a few centimeters of silt, clay or peat (Fyles 1963)

The mean annual temperatures range from $9^{\circ} \mathrm{C}$ to $11^{\circ} \mathrm{C}$ with an annual precipitation of between 660 mm and 1520 mm .

The Little Qualicum River flows from Cameron Lake to Qualicum Beach. Near its mouth, the river's mean annual discharge is 11.8 cubic meters per second. The monthly average flow is highest in December at 23.6 cubic meters per second and lowest at 2.16 cubic meters per second in August. (Environment Canada data averaged over the years from 1960 to 1982).

The Little Qualicum River estuary (Figure 2) is in the Coastal Douglas Fir Biogeoclimatic Zone. The diverse flora are described in detail by Dawe (1976, 1980). Some areas are covered with mature second growth conifers such as Douglas Fir, Western Red Cedar, Western Hemlock, Grand Fir and Sitka Spruce. Big-leaf Maple is interspersed throughout. Sword Fern (Polystichum munitum) and Oregon Grape (Berberis nervosa) dominate the forest floor. Other areas have a more open canopy with Waxberry (Symphoricarpus albus), Salmonberry (Rubus spectabilis) and Nootka Rose (Rosa nutkana) occupying the shrub understorey. Upland grassy fields, hedgerows and beach spit areas lie beyond the forest margin. On the estuary flats, Carex lyngbyei, Juncus balticus, Potentilla pacifica, Agrostis alba var. stolonifera and Triglochin maritimum predominate. Dendritic tidal channels that cross the flats are lined with monospecific stands of the tall form of the sedge Carex lyngbyei (Dawe 1982a).

All five species of salmon as well as Steelhead and Cutthroat Trout depend on the Little Qualicum River. Most of the salmon using the river are Chum; the run of this species was 65,000 fish in 1974 and it has been reported to sometimes exceed 100,000 . Chum begin to gather at the river mouth in late September and early October waiting for the fall rains to swell the river. Dead fish can be seen in small numbers in mid-October and, by the end of November, the carcasses lie strewn along the banks and over much of the estuary. If the carcasses are not washed out to sea, large numbers of scavengers concentrate at the river mouth. Through May and June thousands of juvenile salmon can be found in the river and estuary.

Figure 1. Location of the Little Qualicum River estuary (adapted from Dawe 1976).

Figure 2. Air photo of the Little Qualicum River estuary in June 1974 showing the study area (Marshall-Stevenson Unit of the Qualicum National wildlife Area).

Pacific Herring spawns provide another significant resource for some birds. The timing of the spawn was regular over the study period (in mid-March 1975, on 14 March 1976, 17 March 1977, 15 March 1978 and 8 March 1979); 78\% of all recorded herring deposition occurs in March (Webb and Hourston 1979). However, the size of the spawn varies; in 1976 the spawn was much larger than in any of the other years of the study period. Herring fry do not become plentiful until approximately 2 weeks after the peak spawn (Phillips 1984).

The study area is almost entirely within the Marshall-Stevenson Unit of the Qualicum National Wildlife Area (Figure 3) which encompasses approximately 50 hectares. The only exception is the stretch of beach between the Wildlife Area and Brant Point; the intertidal portion is now managed as part of the Parksville Qualicum Beach Wildlife Management Area but the beach spit is privately owned and includes suburban housing as well as vacant land.

## Methods and Limitations

The senior author covered the study area on foot, and using binoculars and a telescope, counted and recorded all birds observed or heard along a regular survey route (Figure 3 ).

Surveys were conducted at varying intervals, usually weekly or biweekly, from 19 January 1975 through 25 May 1979 (see Appendix I).

The numbers of birds recorded are considered to be generally accurate for the areas surveyed but are undoubtedly conservative due to inherent limitations (see Dawe 1982b). Poor visibility due to weather, and birds underwater or shielded by vegetation during the period of observation would lead to an underestimation of the numbers of birds recorded. The data are based on observations at a particular point in time and do not necessarily reflect the total bird use of the area under observation. For example, birds dependent on the estuary only for a few days during spring and autumn migration could be missed altogether if observation periods occurred on either side of their arrival and departure. Also, data were not collected at night; however, low tides on the study area during the winter months occur mostly during the night. Thus, in winter, observations were not made when the intertidal areas and algal beds were exposed, i.e. at times when they would likely be used by birds such as dabbling ducks.

Survey data were summarized using BASIC programs written by Allan Keller, CWS, and modified for seasonal summaries and statistics by the senior author (see Appendices III and IV). The summarized data were analyzed and much of the first draft of the report written by Ron Buechert under contract to the Mid Island wildlife watch Society. His contribution was reviewed and edited by the senior author.

Figure 3. The Little Qualicum River estuary showing bird survey route, habitats and boundaries of the Marshall-Stevenson Unit, Qualicum National Wildlife Area (adapted from Dawe 1976).

## Results and Discussion

## Bird Use of the Wetland Area

Over the survey period, 173 species of birds were identified in the study area at the Little Qualicum River estuary. (A checklist of these species can be found in Appendix III). A total of 197,157 birds was recorded over 145 surveys. The counts for each survey are given in Appendices IV and $V$.

To estimate the minimum number of birds dependent on the Little Qualicum River estuary, the one-day maximum numbers of birds of each species were summed (Table 1). If the data for the entire 4.5 years of study were taken as a whole, a minimum of 37,271 birds depended on the Little Qualicum River estuary for some aspect of their life history during that period.

Applying this method to each year studied, minimum bird use of the estuary varied: 6814 birds in 1975 (Table 2); 15,832 birds in 1976 (Table 3); 14,437 birds in 1977 (Table 4); 16,146 birds in 1978 (Table 5) and 26,475 birds in 1979 (Table 6). In spite of year to year differences in the quantity and timing of surveys (Appendix I), the estimates for the minimum numbers of birds in 1976, 1977 and 1978 are relatively constant (approximately 15,300 birds). This estimate of mean yearly bird use seems to be supported by the average figure for the five years studied; on average at least 15,905 birds depended on the estuary each year.

The low totals for birds recorded in 1975 when 42 surveys were undertaken contrasts with the high totals for 1979 when we conducted only 9 surveys. No doubt this reflects whether a survey happened to coincide with the peaks of a particular bird activity. For example, over 13,000 gulls were observed on a single survey during the Pacific Herring spawn of March 1979; the peaks observed on surveys in other years were between 4000 and 7000 gulls except in 1975 when the peak numbers were below 400 gulls. However, the largest number of gulls observed in the study area was 53,000 counted during the herring spawn of 1976; that count did not occur during a survey.

Fluctuations within a similar wide range were also observed on the Englishman River estuary 15 kilometres to the southeast (Dawe et al. 1994). Using the same method on the data for the Englishman, a minimum of over 33,000 birds depended on that habitat in 1979-1980 whereas in 1988-1989 the minimum number recorded there was just over 8000 birds. The authors point out that these figures would have been similar if the tally omitted the one-day count of over 25,000 gulls that congregated during a major herring spawn in 1979-1980.

Table 1. Estimeted minimum numbers of birds dependent on the Little Qualicum River estuary, 19 January 1975 through 25 May 1979 , based on the maximum number of each species observed on migratory bird surveys. For species names, see Appendix III.

Table 6. Estimated minimum numbers of birds dependent on the Little Qualicum River estuary 1 December 1978 through 25 May 1979, based on the maximum number of each species observed on bird surveys. For species names, see Appendix III.

## Seasonal Numbers

Winter: Figure 4 shows the proportion of species group use on the estuary in the 5 winters surveyed. Waterfowl was the prominent group in every winter (consistently about half of all birds); most of the waterfowl were diving ducks except in the winter of 1978-1979 when dabbling ducks were more numerous. The second ranked position was held by the gulls in some years and by the passerines in others; the 2 groups were often close in numbers but in the winters of 1976-1977 and 1978-1979 the gulls were several times more numerous than the third ranking passerines. Throughout the study, the total number of birds seen each winter (Appendix II) was lower than the number of birds seen in the spring or autumn. This is only partly explained by the lower number of surveys in winter.

Spring: Figure 5 shows the proportion of species group use on the estuary in the springs of 1975 to 1979. The gulls and the waterfowl shared the top; gulls had the highest proportion in 1976, 1977 and 1979 (approximately $50 \%$ ) whereas the waterfowl, never far behind, ranked first in 1978 and 1975. Passerines were the third most abundant group except in 1978 when the numbers of grebes counted were slightly larger. In 4 of the 5 years surveyed, spring had the highest seasonal total (Appendix II).

Summer: Figure 6 shows the species group use on the estuary in summer; the proportions are almost constant over the 4 summers surveyed. Approximately half of the birds seen were passerines and the gulls ranked second with approximately $25 \%$ of the total. The next most numerous taxonomic groups were the waterfowl followed by the shorebirds except in 1975 when the shorebirds ranked just ahead of the waterfowl and the combined number of birds recorded in the "other" category was also relatively large. In general, there were fewer birds counted in summer than in other seasons. For a comparison of the number of surveys in each season and the total number of birds counted each season refer to Appendices I and II.

Autumn: Figure 7 shows the proportion of species group use on the estuary in each autumn surveyed. Waterfowl were the highest user group, accounting for more than half of all birds seen in 1976 and 1978. In 1975 and 1976, most of the waterfowl tallied in autumn were diving ducks whereas in 1977 and 1978 the majority was dabbling ducks. Gulls ranked second and passerines third in 1975, 1976 and 1978 but 1977 was different; passerines ranked second and grebes third. Autumn had the second highest seasonal total in 3 of the 4 years surveyed (Appendix II).

Figure 7. Proportional species group use of the Little Qualicum River estuary each autumn from 1975 to 1979.

## Species Composition

The following annotated species list includes summarized data from the survey period. Species groups are presented in taxonomic sequence. Within each group or subgroup, species are discussed in decreasing order of highest use of the estuary during the survey.

Loons: Four species of loons were recorded over the study period: the Pacific Loon was the most abundant followed by the Common Loon, the RedThroated Loon and the Yellow-billed Loon. A combined total of 1215 birds were observed ( $<1 \%$ of all birds). Seasonal fluctuations in the numbers of all loons combined are shown in Figure 8.

Pacific Loon numbers totalled 712 birds over the study period (59\% of all loons). Although they were seen in every season, most of the birds were recorded in spring (69\%) and winter (18\%). Four days account for $75 \%$ of all of the birds seen: 20 March 1978-227, 12 April 1976-210, 4 February 1976-55 and 31 January 1977-44. The presence of this species was intermittent; in all seasons there were periods 3 to 12 weeks long in which no Pacific Loons were seen. Most birds were seen offshore.

The Common Loon used the estuary in lower numbers but more consistently than the Pacific Loon; the total seen in the study was 440 birds. It was present in every season with a high frequency of occurrence (usually above 65\%). Numbers were highest in spring (36\%) and autumn (32\%) and lowest in summer (10\%). The peak number was 40 birds recorded on 20 March 1978. Most birds were observed between Brant Point and the river mouth.

A total of 49 Red-throated Loons was recorded. The majority were spring migrants: 4 March 1975-2, 11 March 1975-34, 12 May 1977-3, 5 May 1978-2. Most of the remainder occurred in autumn: 1 October 1975-1 and 8 October 1975-5.

Three Yellow-billed Loons were seen: 8 March 1973-1 (Dawe 1976), 4 March 1976-1 and 4 January 1977-1.

Grebes: Four species of grebes were recorded: Western, Horned, Red-necked and Pied-billed. Their combined total was 5391 birds ( $3 \%$ of all birds). Seasonal fluctuations in the numbers of all grebes combined are shown in Figure 9.

The Western Grebe was by far the most abundant of the grebes with a total of 4900 birds seen ( $91 \%$ of all grebes). The timing of the migrations and the numbers involved varied. The earliest arrival recorded during the study period was on 20 September (1976) and the latest departure was a single straggler on 27 June (1977). The peak numbers in the spring movement were: 25 February 1975-239, 20 March 1978-586, 22 March 1979-286 and 12 April 1976-252. Each of these 4 large groups accounted for more than half of the Western Grebes seen in that season. The only exception was in spring, 1977, when comparatively few Western Grebes were seen ( 17 birds total). Birds were not seen outside of the broad migration periods described. Although large congregations of this gregarious grebe are often associated with Pacific Herring spawns in the spring (Campbell et al. 1990), the peak number seen in this study was 1600 birds on 17 October 1977. However Dawe (1980) recorded 4800 Western Grebes in the study area at about the time of a Pacific Herring spawn on 14 March 1976.

Figure 8. Seasonal fluctuations in numbers of loons on the Little
Qualicum River estuary, winter 1974-1975 through spring 1979:
1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line (b); 1978 - dotted line(b); 1979 - dashed line(b).
Note: Each year begins with data from December of previous year.

Figure 9. Seasonal fluctuations in numbers of grebes on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line (b); 1978 - dotted line(b); 1979 - dashed line (b). Note: Each year begins with data from December of previous year.

A total of 343 Horned Grebes was seen during the surveys ( $6 \%$ of all grebes). The earliest arrival occurred between on 23 August (1976) and the latest departure was 20 May (1975); Horned Grebes were not recorded outside of this overwintering period. Seasonal numbers were highest in autumn (45\%) when a peak of 26 birds was recorded on 4 October 1976; the spring numbers (32\%) were also higher than those of winter ( $22 \%$ ).

We saw a total of 147 Red-necked Grebes over the study period. The earliest arrival was 22 August (1977) and the latest departure was 15 May (1975); outside of this period each year the species was not seen. Most of the birds were seen in autumn (65\%); a peak of 17 grebes was observed on 1 October 1975. The total number of Red-necked Grebes counted in winter and spring over the study period was almost equal. Abundance of this species on the estuary (based on a ratio of the number of birds seen each year over the number of surveys done) declined by approximately $50 \%$ during the study but the data is too limited to draw any conclusion. The species was on the 'Blue List' (threatened status) during the entire study period but was delisted in 1982 due to an apparent increase in numbers at that time (Campbell et al. 1990).

One Pied-billed Grebe was recorded using the estuary on 19 August 1975.
Cormorants: Two species of cormorants were recorded with a combined total of 116 birds ( $<1 \%$ of all birds). The total numbers of Pelagic Cormorants and Double-crested Cormorants identified were equal. In addition, a total of 8 birds was recorded simply as cormorant species. For seasonal fluctuations in the numbers of all cormorants combined, see Figure 10.

A total of 54 Double-crested Cormorants was observed. This species is an uncommon resident on the estuary. It occurred mostly in summer (57\%); in spring and autumn, the average numbers were equal (20\%) and only 1 bird was seen in winter. A peak of 8 birds was recorded on 9 August 1975.

The total number of Pelagic Cormorants was also 54 birds. However, in contrast with the Double-crested Cormorant, most of the Pelagic Cormorants were seen in autumn (54\%) and summer (31\%); 4 birds were seen the winter and 4 birds in the spring. The maximum number seen in a day was 6 birds on 27 September 1976.

Herons: The Great Blue Heron was the only species of heron reported over the study period; a total of 301 birds were seen ( $<1 \%$ of all birds). The highest numbers of herons occurred in summer ( $37 \%$ ); the lowest counts were made in winter (13\%). The frequency of occurrence was high, usually above $66 \%$. A peak of 15 individuals was recorded on 17 June 1977.

Swans: A total of 161 swans was reported during the study period ( $<1 \%$ of all birds). All were Trumpeters except 7 birds that were recorded simply as swan species. The earliest arrival each year occurred from 14 to 24 November and the latest departure usually on 20 to 23 March; during the period of their stay, the frequency of occurrence was usually above $66 \%$. Most Trumpeter Swans were observed in winter ( $68 \%$ ) with a peak of 14 birds occurring on 25 January 1979 and again on the 1 February 1979.

Figure 10. Seasonal fluctuations in numbers of cormorants on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line $(b) ; 1978$ - dotted line(b); 1979 - dashed line(b). Note: Each year begins with data from December of previous year.

Geese: Four goose species with a combined total of 10,361 birds ( $5 \%$ of all birds) were recorded during the study period. The Brant was the most abundant; a total of 10,197 was tallied ( $98 \%$ of all geese). All of the Brant passed through in spring except for 14 individuals seen on 6 September 1976. The earliest arrival was observed during the first 4 days of March, whenever those days were surveyed (1975, 1976, 1977 and 1978). The latest departure occurred between 25 April (1977) and 17 May (1976). In our surveys, the numbers of Brant always peaked during the early part of their presence on the estuary: 657 birds on 15 April 1975, 1359 birds on 23 March 1976, 527 birds on 28 March 1977, 649 birds on 20 March 1978, and 513 birds on 22 March 1979 (Figure 11).

We saw a total of 153 Canada Geese: 20 birds on 27 October 1975, 123 birds on 12 October 1976, 2 birds on 29 November 1976, 2 birds on 6 December 1976, 1 bird on 7 July 1977, 1 bird on 23 October 1978, 2 birds on 25 January 1979 and 2 birds on 1 February 1979.

A total of 9 Greater White-fronted Geese were seen during the study: 3 birds on 16 September 1975, 1 bird on 6 September 1976 and 5 birds on 12 October 1976.

The Snow Goose was seen twice: 1 bird on 20 October 1975 and 1 bird on 27 October 1975.

Dabbling Ducks: During the study period, 9 species of dabbling ducks were recorded representing a total of 15,905 birds ( $8 \%$ of all birds). The most abundant were the Mallard and the American Wigeon followed by the Green-winged Teal. The remaining species (together comprising $<3 \%$ of dabbling ducks) were: Northern Pintail, Blue-winged Teal, Eurasian Wigeon, Gadwall, Northern Shoveller and Wood Duck. During the autumn, a number of birds were reported simply as dabbling duck species; these amounted to a total of $4 \%$ of all dabbling ducks seen during the study.

Seasonal fluctuations in numbers of dabbling ducks are shown in Figure 12. Arrivals began in small numbers at the end of August and continued until the beginning of October when the numbers jumped; $58 \%$ of all dabbling ducks were reported in autumn. Through the winter, counts were also frequently high but by February the numbers on the estuary were dropping back to the low levels present in summer, as described for each species. The peak number during the study was 1113 birds recorded on 29 December 1978.

We saw a total of 6936 Mallards ( $44 \%$ of dabbling ducks). They were reported in every season of the study period but their numbers were comparatively low and their presence was discontinuous in spring (frequency of occurrence 64\%) and even lower in summer; the period from 7 July to 9 August had no sightings at all. The Mallard was seen most in winter (55\%) and autumn $(42 \%)$ when it was recorded on almost every survey. Each year numbers began to climb at the beginning of October (Figure 13) and later reached a peak: 198 birds on 11 February 1975, 200 birds on 23 November 1976, 463 birds on 21 November 1977 and 833 birds on 29 December 1978. By the beginning of March, numbers had returned to the low levels of spring and summer. Normally, 1 or 2 broods are produced each year on the estuary.

American Wigeon numbers totalled 6515 birds over the study period (41\% of dabbling ducks). The earliest arrival was a single bird on 26 August (1976)

Figure 11. Seasonal fluctuations in numbers of Brant on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line(b). Note: Each year begins with data from December of previous year.

Figure 12. Seasonal fluctuations in numbers of Dabbling Ducks on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line $(b) ; 1978$ - dotted line(b); 1979 - dashed line(b).

Figure 13. Seasonal fluctuations in numbers of Mallards on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line (b); 1978 - dotted line(b); 1979 - dashed line (b). Note: Each year begins with data from December of previous year.
and the latest departure occurred each year between 26 March (1975) and the 27 April (1979) with the exception of 2 stragglers seen on 12 May (1977). Seasonal fluctuations in the numbers seen are shown in Figure 14. The majority of American Wigeons were seen in autumn (70\%); the height and the timing of the peak numbers in the autumn migration were relatively consistent: 638 birds on 8 October 1975, 581 birds on 23 November 1976, 481 birds on 31 October 1977 and 610 birds on 23 October 1978.

The Green-winged Teal was the third most abundant dabbling duck with a total of 1331 birds ( $8 \%$ of dabbling ducks). The earliest arrival was 17 August (1976) and the latest departure was 19 May (1977). Seasonal fluctuations in the abundance of Green-winged Teal are shown in Figure 15. Numbers were usually highest in autumn ( $53 \%$ of all Green-winged Teal) and winter ( $36 \%$ ) but even then the presence of these ducks was erratic; the probability of seeing a Greenwinged Teal on the estuary for any day in autumn ranged over the years from $50 \%$ to $89 \%$; for winter it ranged from $0 \%$ to $100 \%$. Peak numbers were recorded: 60 birds on 8 October 1975, 69 birds on 5 November 1976, 150 birds on 19 January 1977 and 23 Birds on 23 October 1978.

Northern Pintail numbers totalled 362 birds ( $2 \%$ of dabbling ducks). The earliest arrival dates in the autumn migration were from 17 August to 29 August (in 1975, 1976 and 1977). Most pintails had left by the end of November but 1 or 2 birds either stayed on or returned occasionally in December, January and February; the latest departure was 18 February 1975 during this study. The year 1978 appears to be unusual in that the first record on the estuary was 20 pintails on 23 October; this might be explained by the lack of surveys in August and September of that year. Nevertheless, in this study it was unusual for 12 birds to be seen on 29 December 1978, and 8 birds on 25 January 1979. In total over the years surveyed, the species was seen most in autumn (78\%) when the following peak numbers were recorded: 45 birds on 8 October 1975, 21 birds on 4 October 1976 and 70 birds on 19 September 1977.

A total of 50 Blue-winged Teal were tallied during the survey. The earliest arrival was 10 May (1976) and the latest departure was 23 August (1976). Most of these teal were seen in the summer of 1976 ( 28 birds) when a peak of 7 birds was recorded 3 times. The remainder were seen in the spring of 1976 ( 2 birds), in the spring of 1977 ( 16 birds) and in the summer of 1977 ( 4 birds). Overall, the peak number recorded was 8 birds on 12 May 1977 and again on 19 May 1977. There were no Blue-winged Teal seen in 1975, 1978 or 1979; however, there were 3 teal recorded simply as teal species.

We saw a total of 16 Eurasian Wigeon over the study period: 10 birds in winter, 5 birds in autumn and 1 bird in spring. The earliest arrival occurred on 26 October (1976) and the latest departure was 11 February (1975) except for 1 bird recorded on 28 March 1977. The maximum of 2 birds was recorded on 2 occasions.

Four Gadwall were observed over the study period: 2 birds on 21 December 1975 and 2 birds on 13 January 1976.

Three Northern Shovellers were reported over the study period: 1 on 17 August 1976, 1 on 22 August 1977 and 1 on 21 November 1977.

Two Wood Ducks were reported on the estuary on 17 October 1977.

Note: Each year begins with data from December of previous year.

Diving Ducks: During the study period, 14 species of diving ducks were recorded with a combined total of 60,083 birds ( $30 \%$ of all birds). The most numerous group was the scoters with a combined total of 36,201 birds ( $60 \%$ of all diving ducks) which included the Surf Scoter, the Black Scoter and the Whitewinged Scoter; however $61 \%$ of this total for all scoters was reported simply as scoter species. After the scoters, the Oldsquaw was the most abundant diving duck followed by Common Goldeneye, Greater Scaup, Bufflehead, Common Merganser and Harlequin Duck. The remaining species (together comprising < $1 \%$ of all diving ducks) were: Red-breasted Merganser, Hooded Merganser, Barrow's Goldeneye, Ruddy Duck and Ring Necked Duck.

From a summer population that was usually between 10 and 150 diving ducks, numbers increased through autumn (Figure 16) and reached an autumn migration peak of between 475 and 800 birds in November or December, then declined slightly through the remainder of winter. However, the greatest numbers of diving ducks were observed in spring ( $67 \%$ ) when single-day counts of over 1000 birds occurred: 1257 birds on 15 April 1975, 1160 birds on 5 April 1976, 3372 birds on 12 April 1976, 1379 birds on 20 April 1976, 1147 birds on 25 April 1977, 6398 birds on 20 March 1978, 7214 birds on 15 March 1979 and a peak of 8764 birds on 22 March 1979. In some years the highest numbers were in conjunction with a Pacific Herring spawn in mid March but in most years the peak was in April. The majority of surviving herring eggs would likely be hatching at that time and the numbers of juvenile Chum would be starting to increase.

The most abundant of the scoters identified was the Surf Scoter, with a total of at least 6521 birds ( $11 \%$ of all diving ducks). The birds were present in every season but in July and August numbers were low (< 15 birds) and occurrence sporadic. Most Surf Scoters were seen in spring (78\%) when the following peaks were recorded: 1147 birds on 15 April 1975, 977 birds on 20 April 1976, 805 birds on 25 April 1977, 466 birds on 26 April 1978. The only survey in April of 1979 did not record any Surf Scoters. During autumn and winter the number of Surf Scoters on the estuary was usually between 10 and 100 birds; there were no consistent peaks to mark autumn movements (Figure 17).

The number of Black Scoters identified totalled 4350 birds ( $7 \%$ of all diving ducks). The earliest arrival occurred in the period from 26 September to 23 October and the latest departure was from 25 April to 5 May except for 3 birds seen on 6 June 1977. Black Scoters were seen most in spring (42\%) and autumn (34\%); the numbers of Black Scoters in autumn always exceeded the numbers of Surf Scoters during this study. Spring migrational peaks of more than 175 Black Scoters occurred consistently in April; the highest number observed during the study was 346 birds on 12 April 1976. Autumn migration was marked by lesser peaks, as shown in Figure 18.

We recorded 3204 White-winged Scoters ( $5 \%$ of all diving ducks). The earliest arrivals came in September or October and the latest departures by 1 July except in 1976 when 3 birds were seen on the estuary on 3 August. The White-winged Scoter, unlike the other 2 scoters, was most abundant in autumn (38\%) and winter (37\%). Peaks numbers occurred within a 3 week period in autumn: 182 birds on 7 November 1975, 139 birds on 23 November 1976, 86 birds on 31 October 1977 and 66 birds on 23 November 1978 (Figure 19).

Note: Each year begins with data from December of previous year.

The most abundant diving duck after the scoters was the Oldsquaw with a total 7629 individuals seen ( $13 \%$ of all diving ducks). The earliest arrival recorded during the study was 18 October (1976) and the latest departure was 19 May (1977). During this period, the frequency of occurrence was low (33\% on average), in spite of their high numbers. Almost all of these ducks were seen in spring (99\%); 3 surveys which coincided with the spawning of Pacific Herring account for $96 \%$ of all the Oldsquaw seen: 1290 birds on 20 March 1978, 2800 birds on 15 March 1979 and 3230 birds on 22 March 1979. Peak numbers for other years illustrate the irruptive nature of this species on the estuary: 61 birds on 15 April 1975, 39 birds on 23 March 1976 and 34 birds on 18 April 1977.

Two species of Goldeneye were reported during the surveys. The Common Goldeneye ranked fifth in abundance among the diving ducks with a total of 5595 birds seen ( $9 \%$ of all diving ducks). The earliest arrival was reported in the period from 6 October to 3 November of each year and the latest departure occurred from the end of March to 15 May. From the first to the last sighting of each year, between 10 and 100 Common Goldeneye were present almost continuously (Figure 20); the frequency of occurrence was $100 \%$ in winter, $87 \%$ in autumn and $70 \%$ in spring. Nevertheless, most of the birds (65\%) were seen in spring. The peak number for each year was: 135 birds on 17 November 1975, 470 birds on 12 April 1976, 53 birds on 19 January 1977, 502 birds on 20 March 1978 and 1611 birds on 15 March 1979.

Two Barrow's Goldeneye were observed over the study period: 1 bird on 26 April 1976 and 1 bird on 13 December 1978.

A total of 4488 Greater Scaup was reported ( $7 \%$ of all diving ducks). Their earliest arrival each year was reported from 27 September to 23 October and the latest departure occurred from 15 March to 12 May. Between first and last appearances, the scaup's presence on the estuary was not continuous (average frequency of occurrence $=64 \%$ during those times). No scaups were seen in summer. Numbers were highest in spring ( $88 \%$ of all Greater Scaups) when scaups were sometimes present in large numbers (especially in 1976) among the many other diving ducks congregating as a prelude to migration and possibly feeding on newly hatched Pacific Herring fry or arrivals of juvenile Chum Salmon. However, in other years (especially 1975 and 1977) most or all of the Greater Scaup had apparently left the area prior to the major congregation of diving ducks in April. This is illustrated by a comparison of seasonal fluctuations in the numbers of Greater Scaup (Figure 21) with the fluctuations in the total numbers of diving ducks (Figure 16). Peak numbers of scaup for each year varied: 179 birds on 26 March 1975, 1840 birds on 12 April 1976, 18 birds on 19 January 1977, 450 birds on 20 March 1978, 360 birds on 15 March 1979.

Note: Each year begins with data from December of previous year.
a

b

Figure 21. Seasonal fluctuations in numbers of Greater Scaups on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line(b).

The total number of Bufflehead seen over the study period was 2698 birds ( $4 \%$ of all diving ducks). During this study, the earliest arrival was always seen in the period from on 23 October to 31 October and the latest departure occurred from 25 April to 7 May, except for 1 straggler on 15 May 1975 and another on 6 June 1977. While overwintering, Bufflehead used the estuary almost continuously (frequency of occurrence $=97 \%$ on average). The numbers present fluctuated from week to week (see Figure 22) but the average number seen in each season remained relatively constant; in spring $37 \%$ of all Bufflehead were tallied, in winter $33 \%$ and in autumn $29 \%$. The peak number for each year sometimes occurred in the spring migration and sometimes in the autumn: 106 birds on 17 November 1975, 97 birds on 12 April 1976, 57 birds on 31 October 1977, 82 birds on 14 November 1978 and 150 birds on 22 March 1979.

Three species of mergansers were recorded. The Common Merganser, with a total of 1842 birds tallied ( $3 \%$ of all diving ducks), was by far the most abundant; it was observed in every season on almost every survey (frequency of occurrence $=89 \%$ overall). Seasonal fluctuations in the numbers of Common Mergansers are shown in Figure 23. Winter had the highest seasonal average (30\%) due mainly to the peak of 267 birds seen on 13 December 1978; the counts for summer ( $27 \%$ ), spring ( $25 \%$ ) and autumn ( $18 \%$ ) were close behind. Other peaks occurred at various times of year: 38 birds on 22 July 1975, 49 birds on 20 September 1976, 49 birds on 28 March 1977 and 56 birds 1 March 1978.

The Red-breasted Merganser was the second most abundant merganser with a total of 164 birds reported. The birds were seen in every season but the numbers varied. The largest numbers were seen in autumn (49\%) and spring (37\%); far fewer were seen in winter (12\%) and summer ( $2 \%$ ). Peaks were recorded at various times of the year: 16 birds on 10 November 1975, 8 birds on 4 February 1976, 17 birds on 19 September 1977 and 13 birds on 20 March 1978.

Hooded Merganser numbers totalled 29 birds. During the study, the earliest arrival always occurred in the period from 7 to 27 October and the latest departure from 21 January to 14 February. Most of the birds were seen in autumn ( $72 \%$ ) and the remainder occurred in winter. The peak number of 4 birds was recorded on 7 October 1977.

We saw total of 1382 Harlequin Ducks. They occurred in every season surveyed, however there was a period of approximately 4 to 8 weeks each summer when no Harlequin Ducks were present (Figure 24). The earliest arrival each year occurred from 17 August to 26 September (excluding 1978 because August and September were not surveyed) and the latest departure occurred from 6 June to 21 June. During autumn, winter and spring the frequency of occurrence averaged $68 \%$. The species was most abundant in spring (32\%) and autumn (31\%); counts in winter (19\%) and summer (18\%) were lower. The following peak numbers indicate that Harlequin Ducks did not congregate during herring spawns on the Little Qualicum River estuary: 76 birds on 27 May 1975, 62 birds on 14 June 1976, 62 birds again almost one year later on 6 June 1977 and 85 birds on 5 May 1978.

Three Ruddy Ducks were seen: 1 bird on 29 December 1978 and 2 birds on 1 February 1979.

The Ring-necked Duck was seen twice: 1 bird on 13 December 1979 and 1 bird on 29 December 1979.

Note: Each year begins with data from December of previous year.

Raptors: The total number of raptors seen was 615 birds ( $<0.5 \%$ of all birds) representing 11 species.

The Bald Eagle was by far the most abundant raptor; a total of 555 was tallied ( $90 \%$ of raptors) over the study. Its presence was recorded in every season (frequency of occurrence $=61 \%$ ). Numbers were lowest in autumn (5\%) and summer ( $5 \%$ ); most of the birds were seen in winter ( $80 \%$ ) because of the presence of spawning chum salmon. Survey counts are especially high when the salmon carcasses are not flushed out of the system by high water. The Bald Eagle has been observed taking scoters and goldeneye on the estuary; for a detailed description, see Dawe (1976 and 1980). In this study, the 3 highest counts were: 96 birds on 13 December 1978, 51 birds on 21 December 1975 and 30 birds on 19 December 1977.

The observed numbers of Osprey totalled 20 birds ( $3 \%$ of raptors). During the first year, 1 or 2 Ospreys were seen using the estuary on 10 of the 14 surveys done in the period from 11 June 1975 to 10 September 1975 (frequency of occurrence $=71 \%$ ). Dawe (1976) recorded the Osprey on the estuary as early as 28 April (1975) and as late as 10 October (1975); it was observed regularly hunting over open water during that year. The following year 1 or 2 birds were reported on 5 of the 22 surveys from 26 April 1976 to 20 September 1976 (frequency of occurrence $=23 \%$ ). In 1977, there were only 3 sightings of one individual each on 4 May 1977, 6 June 1977 and 26 July 1977 (frequency of occurrence $=33 \%$ ). No ospreys were recorded in the surveys of 1978 and 1979.

There were 13 records for the Merlin, all involving lone birds; most of them were seen in the summer and autumn. The earliest arrival was 28 June (1976) and the latest departure was 26 September (1977), except for 1 individual recorded on 15 December 1975. Successful hunts by a Merlin of barn swallows, a starling and a peep have been observed on the estuary at various times (Dawe 1976, 1980).

The total number of Cooper's Hawks recorded was 10; a single bird was seen on each of the following dates: 19 January 1977, 18 February 1975, 18 February 1976, 25 April 1977, 8 July 1975, 5 August 1977, 9 August 1976, 29 August 1977, 27 September 1976 and 4 October 1976.

The Sharp-shinned Hawk was sighted 8 times, 1 bird on each of the following surveys: 4 January 1977, 6 June 1977, 5 August 1975, 17 August 1976, 23 August 1976, 1 October 1975, 29 November 1976 and 29 December 1978.

We recorded 2 Turkey Vultures: 1 bird on 30 March 1976 and another on 19 June 1978.

Two American Kestrels were reported during the study period: 1 bird on 15 May 1975 and 1 bird on 26 August 1975.

The Red-tailed Hawk was also seen twice: 1 bird on 6 September 1976 and 1 bird on 23 November 1978.

One Northern Harrier was seen on 9 August 1976.

A single Northern Goshawk was sighted on 3 November 1975.
We recorded one Gyrfalcon on 24 November 1975, seconds after it had taken a female or juvenile Bufflehead. The falcon flew out over open water, mobbed by gulls, until it was lost from sight.

Pheasants, Grouse and Quails: Although the Ring-necked Pheasant is an introduced species, it is now a common sight during every season; a total of 237 birds was recorded in the study. Observed numbers were highest in summer (43\%) and lowest in winter (7\%). The peak number recorded was 16 birds on 3 August 1976. Outside of the surveys, the presence of broods in June and July has confirmed that the species is breeding in the area. Another report involved a female pheasant becoming prey to a juvenile Cooper's Hawk (Dawe 1980).

Two Ruffed Grouse were seen: 1 bird on 27 October 1975 and another on 10 November 1975. Campbell et al. (1990) identify Ruffed Grouse habitat as second growth deciduous and mixed deciduous and coniferous woods or brushy areas with nearby water. Breeding in the forested part of the estuary was confirmed by the presence of young in June and July 1977 (Dawe 1980).

One Blue Grouse was reported on the survey of 27 June 1977.
The California Quail is an introduced gallinaceous bird that, like the Ringnecked Pheasant, has become resident in the area; a total of 12 were counted on the surveys. One or 2 birds were seen occasionally from 29 April 1975 to 14 July 1975 and in the following year 2 birds occurred on 5 April 1976, 1 bird on 12 April 1976 and 1 bird on 7 June 1976. Dawe (1980) noted quail in 1977, 1978 and 1979 (Dawe 1980).

Rails and Coots: The total number of Virginia Rails recorded during the study was 23 birds; most of them were seen in autumn (70\%). In the earliest sightings of the season, a single bird was reported on each of the 4 surveys from 15 July to 22 August 1977. The records for autumn were: 1 bird on 4 October 1976, 1 bird on 23 November 1976 and 1 bird on 29 November 1976; 1 bird on 7 September 1977, 1 bird on 26 September 1977, 2 birds on 7 October 1977 and 2 birds on 14 November 1977; a peak of 7 birds was counted on 23 November 1978. In addition, 2 birds were recorded on 6 November 1976 and 1 bird on 13 December 1978.

The American Coot was seen twice: 1 bird on 19 January 1977 and 1 bird on 14 November 1977.

Cranes: We saw 9 Sandhill Cranes on 12 April 1976.
Shorebirds: In total, 4033 shorebirds ( $2 \%$ of all birds) were tallied on the Little Qualicum River estuary during the surveys. This total includes the records of 19 species plus the more than $8 \%$ of all shorebirds that were recorded simply as shorebird species. In spring, we saw the highest numbers of shorebirds (33\%) inflated by the large numbers of migrating Black Turnstones in April. The shorebird totals for the other seasons were similar to one another. Fluctuations in shorebird numbers are shown in Figure 25.

Figure 25. Seasonal fluctuations in numbers of shorebirds on the Little
Qualicum River estuary, winter 1974-1975 through spring 1979:
1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line (b).
Note: Each year begins with data from December of previous year.

The Black Turnstone was the most numerous shorebird; the total counted during the surveys was 1571 birds ( $39 \%$ of all shorebirds). The earliest arrival each year was a record of 2 or 3 birds in late July and August except in 1978 when those weeks were not surveyed. The autumn migration was more clearly defined by arrivals each year starting in the period from 13 September to 31 October and reaching the following maxima: 38 birds on 24 November 1975, 50 birds on 6 December 1976 and 22 birds on 21 November 1977 (Figure 26). The peak numbers from 1975 to 1979 coincided with the latest departure each spring; from 71 to 155 Black Turnstones were counted on one of the days surveyed from 25 April to 7 May and then the species was not seen again on the estuary until July, August or later. Thus the highest seasonal tally was for spring (57\%) followed by winter (24\%) and autumn (18\%). While on the estuary throughout the winter, these birds were often found among the rocks and gravel near the water's edge from Brant Point to the river mouth. However, during this period (from the 13 September to 7 May), the frequency of occurrence was relatively low (58\%) which indicates that for a significant portion of the time the wintering population of between 20 and 30 birds might have been using areas outside of those surveyed on the Little Qualicum estuary.

A total of 1022 Killdeer was tallied, ranking it as the second most abundant shorebird ( $25 \%$ of all shorebirds). It was present in every season surveyed but there were fluctuations in both numbers and frequency (Figure 27). The Killdeer is "one of the earliest spring migrants in the province," but "the presence of winter residents on the coast masks the arrival of spring migrants there" (Campbell et al. 1990). Most of the birds (45\%) were seen in summer and, not surprisingly, the chance of seeing at least 1 Killdeer on any survey in summer was high (frequency of occurrence $=89 \%$ ). The number of birds seen in spring was the lowest (16\%) but the frequency of occurrence was even higher than in summer (93\%); the birds had dispersed on the estuary and elsewhere for breeding. In 1975, several nests on the estuary were monitored (Dawe 1976). The peak numbers usually occurred in summer: 31 birds on 24 June 1975, 55 birds on 3 August 1976 and 39 birds on 5 August 1977.

The Dunlin accounted for a total of 364 birds, $9 \%$ of the shorebirds tallied. The pattern of this species' presence on the estuary was not consistent over the years studied. The Dunlin seen in summer were early migrants: a single bird, still with remnants of the dark breast patch, was seen on 17 August 1976 and 10 birds occurred on 26 August 1975. The main autumn migration began each year in the period from the 20 October (1975) to 31 October (1977) except in 1978 when no surveys were taken in October. Autumn peaks included: 21 birds on 5 November 1976 and 37 birds on 21 November 1977. Through the winter, the species was seen several times in 1976-1977 and 1977-1978, but not in the winters 1974-1975, 1975-1976 and 1978-1979. The only spring sighting was of 4 Dunlin in full breeding plumage on 25 April 1977. Most of these gregarious little shorebirds were recorded as part of 3 large counts in one winter: 45 birds on 6 December 1976, 76 birds on 4 January 1977 and a peak of 132 birds on 31 January 1977. Autumn ranked second; $23 \%$ of the Dunlin were seen in that season.

Figure 26. Seasonal fluctuations in numbers of Black Turnstones on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line $(b) ; 1978$ - dotted line $(b) ; 1979$ - dashed line $(b)$. Note: Each year begins with data from December of previous year.

Note: Each year begins with data from December of previous year.

The total number of Western Sandpipers reported was 190 birds ( $5 \%$ of all shorebirds); most of the birds were seen in summer (59\%) and spring (38\%). Although the earliest arrival recorded in the study was 7 birds on 26 July 1977 and the latest departure was 1 bird on 27 September 1976, the southward movement appeared to be centered in August; the highest numbers were: 29 birds on 19 August 1975 and 17 birds on 30 August 1976. Spring migration was marked by only 3 sightings: 72 birds on 12 May 1977, 1 bird on 25 May 1976 and 1 late migrant on 6 June 1978. Nevertheless, it is possible that this species of peep also used the estuary in the spring of other years but it went unreported because the surveys did not happen to coincide with its rapid passage through the area

The only other peep recorded regularly in the surveys was the Least Sandpiper with a total of 107 birds seen ( $3 \%$ of all shorebirds), most of them in summer ( $63 \%$ ). The earliest arrival in the autumn migration was 4 birds on 1 July (1975) and the latest departure was 2 birds on 13 September (1976). Adult females travelling south earlier than the adult males and juveniles (Campbell et al. 1990) would explain why peak numbers on the estuary occurred on disparate dates: 15 birds on 14 July 1975, 6 birds on 5 August 1977 and 6 birds on 30 August 1976. The northbound migration was observed: 1 bird on 29 April 1975, 19 birds on 7 May 1975, 9 birds on 12 May 1977 and, as with the Western Sandpiper, 1 late spring migrant noted on 6 June 1978. Dawe (1976) observed the Least Sandpiper most often along the back channel to the estuary flats.

The fifth most abundant shorebird was the Sanderling; a total of 136 birds (3\% of all shorebirds) were counted, most of them in winter (53\%) and spring (24\%). Sightings were intermittent, but over the study period there was a Sanderling record for every month from their earliest arrival, 9 birds seen on 17 August (1976), to the latest departure, 4 birds on 29 April (1975). The winter of 1976 was an exception because Sanderlings were using the estuary almost continuously; 6 birds were seen on 6 of the 12 surveys and the frequency of occurrence for that season was $75 \%$. Other peaks were: 13 birds on 26 August 1975, 10 birds on 4 January 1977 and 9 birds on 22 March 1979. The Sanderlings recorded by Dawe (1976) were found from Brant Point to the mouth of the Little Qualicum River, always in association with Black Turnstones.

We saw a total of 75 Spotted Sandpipers, most of them in summer (77\%). The earliest arrival occurred from 12 May to 27 May and the latest departure by the end of August, except for 3 isolated sightings: 2 birds on 16 September, 1 bird on 31 January 1977 and 1 bird on 26 April 1978. Through the summers of 1975, 1976 and 1977, the species was seen often (frequency of occurrence $=69 \%$ ); it is known to have bred near the river mouth in 1975, 1976 and 1977 (Dawe 1980). The highest count on a single day was 6 Spotted Sandpipers on 6 June 1977.

We also saw a total of 75 Common Snipes; the snipe was seen most in spring (59\%) and autumn (27\%) and not at all in summer. Earliest arrival was 16 September 1975 and latest departure 19 May 1977. Peak numbers occurred during the migrations: 7 birds on 12 October 1976, 7 birds on 1 March 1978, 15 birds on 28 March 1977. The Common Snipe was often seen using the estuary flats or the northeast marsh.

Of the 59 dowitchers seen, 27 birds were identified as Long-billed and 7 were recognized as Short-billed; the remainder ( 25 birds) were simply recorded as dowitcher species. Existing records of habitat use suggest that all dowitchers prefer to use the estuary flats (Dawe 1976).

All of the records for the Long-billed Dowitcher were from the period 12 July to 3 August except for a single spring migrant on 7 May 1975 and 2 isolated records of migrants in autumn: 5 birds on 20 September 1976 and 1 bird on 1 October 1975. Other peak numbers were: 6 birds on 12 July 1976 and 5 birds on 22 July 1975.

Short-billed Dowitcher records were: 1 bird on 17 July 1978, 3 birds on 17 August 1976, 1 bird on 23 August 1976 and 2 birds on 13 December 1978.

A total of 29 Greater Yellowlegs was seen during the study but none of the observations involved more than 3 birds. The spring migration was marked by 6 records ( 9 birds in total) from 15 April to 19 May. Most of the southbound migration occurred from 12 July to 19 August ( 8 records for a total of 14 birds) but there were also 4 records ( 5 birds in total) of birds passing through from 2 September to 23 October. The only winter sighting was 1 bird on 21 February 1978.

During the study a total of 11 Lesser Yellowlegs were counted: 7 birds on 9 August 1976, 2 birds on 22 August 1977, 1 bird on 30 August 1976 and 1 bird on 20 September 1976.

Twenty seven Red-necked Phalaropes were seen on 29 August 1977. All were seen off Brant Point.

One survey recorded 17 Whimbrels on 23 August 1976.
Six Semipalmated Plovers were observed: 1 bird on 17 August 1976, 1 bird just over a year later on 22 August 1977 and 4 birds on 23 October 1978.

The Pectoral Sandpiper was reported twice: 2 birds on 16 September 1975 and 2 birds just over a year later on 20 September 1976.

Two Black-bellied Plovers were seen on 19 September 1977.
The only survey record of Baird's Sandpiper was 2 birds on 17 August 1976.

One Wilson's Phalarope female was recorded on 21 June 1976.

Gulls, Terns and Jaegers: Seven species of gulls, 2 species of terns and 1 species of jaeger were recorded on the Little Qualicum River estuary during the surveys; the combined total was 70,384 gulls ( $36 \%$ of all birds). Of the gulls identified, Bonaparte's Gull, Glaucous-winged Gull, Mew Gull and Thayer's Gull were the most numerous; California Gull, Herring Gull and Ring-billed Gull were also noted.

The majority of gulls (64\%) were reported simply as gull species, therefore analysis of gull use on the estuary requires consideration of the numbers of all gulls combined. Seasonal cycles in the combined numbers of gulls were consistent over the years surveyed (Figure 28). Each year the peak occurred in March when between 450 and 13,500 gulls gathered at about the time of the Pacific Herring spawn. By May the numbers had plunged below 100; nevertheless, spring accounted for $74 \%$ of all gulls seen. During summer, gull use of the estuary was at its lowest ( $6 \%$ of the total); the numbers climbed gradually above 100 and then remained relatively steady (between 100 and 400 birds) in autumn ( $11 \%$ of the total). Through winter ( $9 \%$ of the total) numbers were generally seen to decline until the herring spawn but there were several significant winter peaks recorded: 826 gulls (including 340 Bonaparte's) on 13 December 1978 and 1272 gulls (including 960 Thayer's Gulls) on 14 February 1977.

Of the identified gulls, Bonaparte's was the most abundant with 8858 birds seen in total ( $13 \%$ of all gulls). In the spring migration, the earliest arrival was 5 April (1976) and the peak (maximum = 1,995 birds) occurred in the period from 12 April to 7 May each year (Figure 29). At that time, these little gulls feed heavily on the salmon smolts leaving the river at low tide. From 25 May to 6 July there were fewer than 13 Bonaparte's Gulls on the estuary but thereafter their numbers swelled with south bound migrants; the following peaks were observed: 123 birds on 7 July 1977, 247 birds on 2 September 1975 and 158 birds on 20 September 1976. In 1978 the peak was 340 birds on 13 December 1978; this was the only record of the Bonaparte's Gull in winter. Most of the birds were seen in spring (54\%); the numbers for summer and autumn were equivalent to one another ( $21 \%$ each).

The Glaucous-winged Gull ranked second in abundance of the identified gulls, with a total of 8015 birds ( $11 \%$ of all gulls). The species was present in every season but the numbers were higher in winter (36\%) and autumn (34\%) and lowest in summer (15\%). Although this species is considered the "sea gull" of the coast, found in all coastal habitats at all seasons, it is recognized as having a migration; "in summer flocks are usually small except near colonies and garbage dumps" (Campbell et al. 1990). Many of the following peaks probably match the abundance of food sources such as dead salmon: 164 birds on 31 October 1977, 297 birds on 23 November 1978, 227 birds on 24 November 1975, 293 birds on 29 November 1976, 188 birds on 15 December 1975, 337 birds on 29 December 1978 and 276 birds on 14 February 1977. Peak numbers appear much lower than those for Bonaparte's or Mew gulls but this might be misleading. It is likely that many of the birds recorded as "gull species" during the study were the Glaucouswinged Gull. Seasonal fluctuations in the numbers of Glaucous-winged Gulls are shown in Figure 30.

Figure 28. Seasonal fluctuations in numbers of Gulls on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line (a);
1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line $(b)$.
Note: Each year begins with data from December of previous year.

Figure 29. Seasonal fluctuations in numbers of Bonaparte's Gulls on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line(b).
Note: Each year begins with data from December of previous year.

Figure 30. Seasonal fluctuations in numbers of Glaucous-winged Gulls on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a);
1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line(b). Note: Each year begins with data from December of previous year.

We counted a total of 6556 Mew Gulls ( $9 \%$ of all gulls). They were present almost continuously in every season surveyed except between migrations; from the middle of May to the end of June there were few birds seen (Figure 31). Most of the Mew Gulls in this study were counted on one survey ( 4000 birds on 23 March 1976), probably because of a large Pacific Herring spawn that year. All other annual peaks for this species were much lower: 131 birds on 17 November 1975, 87 birds on 25 April 1977, 247 birds on 1 March 1978 and 85 birds on 13 December 1979. At the time of the herring spawn on the Little Qualicum estuary in 1975 and in 1977 to 1979, most of the birds must have been elsewhere, possibly exploiting peak spawns at other sites. Next to spring, winter and autumn had the highest seasonal totals; summer had the lowest.

We saw 1956 Thayer's Gulls in total ( $3 \%$ of all gulls). This bird winters on the Pacific Coast and breeds in the arctic islands of Canada (Campbell et al. 1990). Its use of the estuary during migrations was not consistent over the years studied; however, it is likely that part of the story is hidden among the large numbers of birds recorded as "gull species" (included in Figure 28). In the first year of study the spring migration was observable over 8 surveys; the earliest arrival was a peak of 117 birds on 18 March 1975 and the latest departure was 15 May 1975. In 1977, spring migration was defined by 3 records: 960 birds on 14 February 1977, 280 birds on 22 February 1977 and 327 birds on 3 March 1977. Mainly as a result of these records, $69 \%$ of all Thayer's Gulls in this study were tallied in spring.

The earliest arrival in the southbound migration was 1 Thayer's Gull on 22 July 1975 and later 6 birds were seen on 2 September 1975, but most of the birds that season occurred from 8 October 1975 to the latest departure on 11 March 1976; 1975-1976 was the only winter when the species occurred often (frequency of occurrence $=65 \%$ over 20 surveys). Peaks were: 23 birds on 27 October 1975, 25 birds on 10 December 1975 and 29 Birds on 4 February 1976. The next period when the birds were seen was from 30 August 1976 until 23 November 1976 ( 4 records for a total of 8 birds). No Thayer's Gulls were seen in the autumn of 1977 , only 1 bird total in 1978 (on 23 November) and a total of 4 birds in 1979, all in December.

The total number of California Gulls seen was 95 birds; most of them in the autumn ( $73 \%$ ). Although the birds seen on Vancouver Island are primarily transients moving to and from breeding colonies in the interior of the continent (Campbell et al. 1990), a few individuals were sometimes noted on the estuary in July or August. In 1975 and 1976 (when all but 3 of the birds were seen), the timing of the peak movements were not close; 17 birds on 20 October 1975 and 11 birds on 3 November 1975 contrasts with 9 birds on 13 September 1976 and 16 birds on 27 September 1976.

A total of 25 Herring Gulls was counted, at least 3 birds in each season: 3 birds on 18 March 1975, 1 bird on 8 April 1975, 1 bird on 20 October 1975 and 1 bird on 27 October 1975; 1 bird on 11 March 1976 and 1 bird on 23 November 1976; 1 bird on 4 January 1977, 6 birds on 14 February 1977 and the peak of 10 birds on 26 July 1977. No Herring Gulls were recorded in 1978 or 1979.

Five Ring-billed Gulls were seen, all in the first year of study: 1 bird on 24 June 1975, 3 birds on 1 October 1975 and 1 bird on 20 October 1975.

Figure 31. Seasonal fluctuations in numbers of Mew Gulls on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a);

The gull family was also represented by 2 species of terns and 1 jaeger recorded during the study period. Their numbers are not included with the gull totals.

The Common Tern was reported 3 times in a period of 4 weeks for a total of 15 birds over the study period: 4 birds on 17 August 1976, 6 birds on 30 August 1976 and 5 birds on 13 September 1976.

Two Caspian Terns were seen on 14 July 1975.
We also saw 1 Parasitic Jaeger on 30 August 1976.
Alcids: A total of 774 alcids ( $<1 \%$ of all birds) were recorded representing 3 species; the total also includes 90 birds that were reported simply as alcid species.

The most numerous alcid was the Marbled Murrelet with a total of 499 birds tallied. The species inhabits protected coastal waters throughout the year; "the centre of the wintering population is the Strait of Georgia, Howe Sound and Juan de Fuca Strait" (Campbell et al. 1990). Nevertheless, there were only 2 winter records from this study: 3 birds on 15 December 1975 and 10 birds on 13 January 1976. Most of the birds were seen in spring (62\%) and summer (26\%) starting on 4 March. Records of 1 or more birds were sometimes regular (frequency of occurrence $=57 \%$ for the 51 surveys in spring and summer of 1975 and 1976) and sometimes intermittent; they continued right through autumn. Peaks were: 214 birds on 5 April 1976, 10 birds on 27 April 1978, 19 birds on 3 May 1976, 16 birds on 5 July 1976 and 29 birds on 10 September 1975.

A total of 158 Pigeon Guillemots was seen; records were from every month except December. The species was most numerous in autumn (39\%), less so in summer and spring ( $30 \%$ in each season) and lowest in winter ( 3 birds). The frequency of occurrence for spring, summer and autumn over the entire study was relatively high (43\%). These statistics support Campbell et al. (1990) in stating that the species is mostly reported from April through September when it can be locally numerous. In contrast with the Marbled Murrelet, the Pigeon Guillemot was not seen on the estuary in large groups; the peak numbers recorded in various months of the study showed only slight fluctuations: 6 birds on 20 March 1978, 6 birds on 5 April 1976 and 12 birds on 20 May 1975; 7 birds on 14 June 1976, 11 birds on 10 September 1975, 10 birds on 4 October 1976 and 9 birds on 17 of October 1977.

We saw a total of 27 Common Murres: 18 birds on 21 February 1978, 2 birds on 22 March 1979, 1 bird on 6 June 1977, 2 birds on 15 July 1977, 2 birds on 3 August 1976, 1 bird on 9 August 1976 and 1 bird on 18 October 1976.

Doves and Pigeons: This group was represented by three species with a combined total of 137 birds. The total count of Band-tailed Pigeons was 109 birds. The earliest arrival was 8 birds on 26 April 1976 and the latest departure was 1 bird on 10 September 1975. Other maxima occurred as follows: 10 birds on 9 May 1977, 11 birds on 19 June 1978, 7 birds on 8 July 1975, 9 birds on 26 July 1977 and a peak of 29 birds on 17 August 1976. Most of the Band-tailed Pigeons were seen in summer (73\%) and spring (26\%).

A total of 26 Rock Doves was seen: 1 bird on each of 5 surveys from 4 March 1975 to 27 May 1975, 5 birds on 10 September 1975, 9 birds on 10 December 1975, 4 birds on 11 March 1976 and 3 birds on 15 March 1979.

Two Mourning Doves were seen: 1 bird on 27 May 1975 and 1 bird on 29 August 1977.

Owls: Three species of owls were recorded during the surveys; the combined total was 8 birds. Four Short-eared Owls were reported: 1 bird on 3 November 1975, 1 bird on 12 February 1976, 1 bird on 18 February 1976 and 1 bird on 29 November 1976.

We reported 3 Western Screech Owls: 1 bird on 12 February 1976 and 2 birds on 25 April 1977.

One Great Horned Owl was recorded on 3 November 1975.
Nighthawks: This group was represented by a total of 67 Common Nighthawks. The earliest arrival was 11 birds on 6 June 1978 and the latest departure a single bird on 10 September 1975. The species was seen in small groups throughout each summer until larger groups began to assemble towards the end of August in preparation for their long migration: 20 birds on 26 August 1975, 9 birds 17 August 1976 and 7 birds on 29 August 1977.

Swifts: The Black Swift was seen in 3 of the 4 summers surveyed; the total was 237 birds over the study. The earliest arrival was 2 birds on 31 May 1976 and the latest departure was a peak of 200 birds seen on 26 August 1975. Other records were: 18 birds on 4 June 1975, 16 birds on 6 June 1978 and 1 bird on 12 July 1976.

We also recorded Vaux's Swift; 2 birds were seen on the survey of 12 August 1975.

Hummingbirds: We saw a total of 192 Rufous Hummingbirds. From the earliest arrival on 5 April (1976) to the latest departure on 20 September (1976), the frequency of occurrence was high (78\%); most of the birds were seen in spring (56\%) and summer (43\%). The peaks for each year was observed in spring: 7 birds on 20 May 1975, 6 birds on each of 3 surveys in April and May 1976, 9 birds on 19 May 1977, 4 birds on 26 April 1978, 3 birds on each of 2 surveys in April and May 1979.

Kingfishers: A total of 234 Belted Kingfishers was seen. This species is a resident; it was present in every season with a high frequency of occurrence ( $84 \%$ over the study). The numbers of birds was highest in summer ( $38 \%$ of the all kingfishers) and autumn (25\%) when a peak of 5 birds was recorded on 15 July 1977 and 17 August 1976 and again on 10 September 1975.

Woodpeckers: Five species were recorded in this group with a combined total of 235 birds.

The Northern Flicker, with a total of 206 birds, accounted for the majority (88\%) of the woodpeckers seen. This species was noted in every season surveyed but most of the birds occurred in summer (31\%) and spring ( $28 \%$ ); numbers peaked at 8 birds on 17 August 1976. The frequency of occurrence over the study period was $64 \%$.

We saw 12 Downy Woodpeckers. All reports were of single birds; they occurred in every year surveyed: 1 report in February, 3 reports in April, 1 report in May, 2 reports in June, 2 reports in July, 2 reports in September and 1 report in November.

A total of 4 Hairy Woodpeckers was seen, one third as many as the Downy Woodpecker. Hairy Woodpeckers occurred as follows: 1 bird on 4 February 1976, 2 birds on 3 May 1976 and 1 bird on 23 November 1978.

Eleven Pileated Woodpeckers were tallied over the study period: 1 bird on 4 February 1976, 1 bird on 14 February 1977, 2 birds 5 April 1976, 1 bird 8 April 1975, 1 bird on 24 June 1975, 1 bird on 28 June 1976, 1 bird on 17 August 1976, 1 bird on 30 August 1976 and 1 bird on 12 October 1976. Note that most of reports occurred in 1976, including the only record of 2 birds.

We saw 2 Red-breasted Sapsuckers on 4 January 1977.
Passerines: Seventeen families representing 68 species and 26,402 birds were tallied ( $13 \%$ of all the birds seen during the study) which ranks the passerines as third in abundance over the study period (after the waterfowl and gulls). Each summer, the passerines accounted for approximately half of all birds seen (Figure 6). Fluctuations in the numbers of passerines over time are shown in Figure 32. Each year the highest seasonal total was in summer except in 1977 when more than half of the passerines counted that year occurred in autumn because of a single survey that reported 4000 European Starlings. The seasonal totals were lowest in winter during 1975, 1977 and 1978.

Flycatchers. Five species of flycatchers were recorded with a combined total of 176 birds including 7 individuals that were recorded simply as flycatcher species.

The Pacific-slope Flycatcher was the most abundant with a total of 108 birds seen ( $61 \%$ of flycatchers). The earliest arrival was 25 April (1977) and the latest departure was 29 August (1977). In each of the years fully surveyed, the peak occurred in July: 4 birds on 8 July 1975, 5 birds on 12 July 1976, 5 birds again on 19 July 1976, 6 birds on 7 July 1977 and 6 birds again on 26 July 1977. These might represent successful family groups. Other years the peaks were: 4 birds on 19 June 1978 and 7 birds on 25 May 1979.

Figure 32. Seasonal fluctuations in numbers of Passerines on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line(b); 1978 - dotted line(b); 1979 - dashed line(b). Note: Each year begins with data from December of previous year.

The second most numerous species in this group was the Willow Flycatcher; a total of 47 birds ( $27 \%$ of all flycatchers) was tallied during the study. The earliest arrival was 2 birds on 25 May 1979 and the latest departure 1 bird on 17 August 1976. Each year the peak usually occurred from late June to mid July: 5 birds on 24 June 1975, 4 birds on 27 June 1977, 5 birds on 12 July 1976 and 5 birds again on 19 July 1976. The only record in 1979 was 2 birds on 25 May.

A total of 12 Western Wood-Pewees was seen. In the first year of study, 7 birds were counted on 4 surveys from 14 July 1975 to 5 August 1975; the most seen was 3 birds. Thereafter, all records were of single birds: 17 May 1976, 25 May 1976, 15 July 1977, 5 August 1977 and 29 August 1977.

We saw 1 Western Kingbird on 25 April 1977.
One Say's Phoebe was seen on 6 September 1976.
Swallows: The swallows were represented by 5 species over the study with a combined total of 1728 birds ( $7 \%$ of the passerines); this number includes 60 individuals ( $5 \%$ of swallows) recorded simply as swallow species.

The Barn Swallow was the most abundant of this group with a total of 1210 birds counted ( $70 \%$ of all swallows). Seasonal fluctuations in the numbers of Barn Swallows is shown in Figure 33. The earliest arrival was recorded each year from 22 April to 27 April and the latest departure was 7 September to 13 September in those years when this period was surveyed (1975-1977). Between its punctual arrival and departure, which generally occurred later in the season than the other swallows, the presence of the Barn Swallow was almost continuous (frequency of occurrence $=98 \%$ ). Most of the birds were seen in summer ( $73 \%$ ) when the following peaks were recorded: 84 birds on 26 July 1977, 90 birds on 29 July 1975 and 56 birds on 17 August 1976.

Second in abundance among the swallows was the Violet-green; 353 birds were recorded ( $20 \%$ of all swallows) during the study. The earliest arrival each year occurred from 11 March and 4 April except in 1978 when the earliest arrival was 26 April. The latest departure occurred from 3 August to 29 August in the years when that period was surveyed (1975 to 1977). Peaks observed in spring were: 25 birds on 22 April 1975, 4 birds on 26 April 1978, 15 birds on 19 May 1977, 11 birds on 25 May 1979. The only survey when the peak number of the year occurred in summer was 22 birds on 15 July 1977. The frequency of occurrence for spring and summer was $66 \%$ over the study period. In contrast with the Barn Swallow, the Violet-green Swallow was seen mostly in the spring (61\%).

A total of 50 Northern Rough-winged Swallows was observed; the numbers were equivalent in summer and spring. Earliest arrival was 2 birds on 22 April 1975 and latest departure was 1 bird on 19 August 1975. The peak number for each year was a record of 3 to 5 swallows in April or May, except when 9 swallows were seen on 29 July 1975.

Figure 33. Seasonal fluctuations in numbers of Barn Swallows on the Little Qualicum River estuary, winter 1974-1975 through spring 1979: 1975 - solid line(a); 1976 - dotted line(a); 1977 - solid line (b); 1978 - dotted line(b); 1979 - dashed line(b). Note: Each year begins with data from December of previous year.

We saw a total of 48 Cliff Swallows, approximately half of them in spring and half in summer. Earliest arrival was 2 birds on 18 April 1977 and latest departure was 2 birds on 9 August 1976. The observed: 5 birds on 29 April 1975 and 6 birds on 1 July 1975 and 4 birds on 31 May 1976.

Seven Tree Swallows were seen: 2 birds on 22 April 1975, 2 birds on 26 April 1976, 2 birds on 29 April 1975 and 1 bird on 5 May 1978.

Crows and Jays: Three species of corvids with a combined total of 4653 birds accounted for $18 \%$ of the passerine total, ranking them as the third most abundant passerine family. Most were the Northwestern Crow ( 4487 birds; $96 \%$ of the corvid total). Crows were present in every season (frequency of occurrence $=96 \%$ over the study period) but the numbers recorded were slightly higher in autumn (32\%) and winter (27\%) and the lowest numbers occurred in summer (19\%). Each year the peak of between 47 and 129 crows was seen in autumn or winter.

Although the Common Raven was seen in all 4 seasons for a total count of 141 birds ( $3 \%$ of corvids), sightings were intermittent (frequency of occurrence $=36 \%$ over the study period). The number of ravens seen on a survey ranged from 1 to 7 birds except on 23 October 1978 when 37 ravens were observed. Over the survey, most of the birds were seen in autumn (38\%) and summer (27\%).

Twenty five Steller's Jays were observed in total; records occurred in every season except summer. Most of the birds were seen in autumn (64\%) when a maximum of 3 jays was counted on 4 October 1976.

Chickadees: The observed number of Chestnut-backed Chickadees was 505 birds in total. The species was seen in every season but not on every survey; the frequency of occurrence varied from $17 \%$ in winter to $79 \%$ in summer perhaps because of seasonal changes in their flocking behaviour. Most of the birds were seen in summer (52\%); the lowest seasonal count was in spring (10\%). Peaks of 20 or more birds occurred at various times of the year: 30 birds on 4 February 1976, 25 birds on 25 February 1975, 20 birds on 4 March 1975, 29 birds on 7 September 1977 and 30 birds on 1 December 1975.

Bushtits: A total of 122 Bushtits was seen; $51 \%$ were tallied in autumn and $46 \%$ in summer. Although the bird is considered resident over all of its range, the Bushtit was not reported in winter and only 4 birds were seen in spring ( 8 March 1977 and 18 April 1977). The frequency of occurrence was variable but generally low ( $13 \%$ over the study). Numbers in excess of 8 birds were seen on only 3 surveys, all in the same year: 18 birds on 19 August 1975, 20 birds on 2 September 1975 and 20 birds on 10 September 1975.

Nuthatches. The numbers of the Red-breasted Nuthatch totalled 55 birds. They were reported in each season but the majority occurred in summer (53\%). All of our records are of 1 or 2 birds except 4 birds seen on 15 July 1977 and 3 birds on 7 September 1977. The frequency of occurrence was high (27\%) relative to the total number of birds seen.

Creepers: We saw 32 Brown Creepers, most of them in summer (56\%) and spring ( $34 \%$ ); the species was not seen in winter. Of the 24 records from this study, 17 were of single birds, 6 records were of 2 birds each and the peak was 3 birds on 20 March 1978. The frequency of occurrence was $17 \%$.

Wrens. Four species of wrens totalling 333 birds were reported during the study period.

We saw a total of 195 Winter Wrens ( $59 \%$ of all wrens). The species was seen in every month except December and January; the majority occurred in summer (46\%) and spring (34\%). As a result the frequency of occurrence ranged from $82 \%$ in summer and $67 \%$ in spring to $20 \%$ in winter. The maximum numbers were 8 birds on 17 August 1976 and 6 birds on 28 March 1977.

The Bewick's Wren, with a total of 88 birds, was the second most abundant wren ( $26 \%$ of wrens). It was seen in every month of the year; the largest proportion of the birds was seen in autumn (34\%) and summer (31\%); the lowest occurred in winter (14\%). Most of the records were of 1 bird the maximum number counted in a survey was 4 individuals: 4 birds on 26 September 1977 and 4 birds on 27 April 1979.

The total number of Marsh Wrens counted was 49 birds; they were seen in summer (19 birds), autumn ( 24 birds) and winter ( 6 birds) but not in spring. Earliest arrival occurred from 26 July (1977) to 23 August (1976); over the study period the bird was recorded in every month thereafter until December 15 (1976). In addition, 1 individual was recorded on 14 February (1977). A peak of 8 birds was seen on 5 August 1977.

One House Wren was seen on 15 July 1977.
Kinglets and Thrushes: The muscicapid family was represented by 9 species with a cumulative total of 1463 birds ( $6 \%$ of all passerines). The American Robin was the most abundant member of the group (67\%); a total of 979 birds was seen. Highest numbers were seen in spring ( $44 \%$ of all robins) and summer (31\%); the seasonal total for winter was the lowest (10\%). Peak numbers of robins were recorded at various times of year: 50 birds on 25 February 1975, 44 birds on 1 March 1978, 19 birds on 4 March 1976, 40 birds on 15 March 1979, 26 birds on 26 July 1977 and 66 birds on 23 October 1978. Continuous periods of absence also occurred at different seasons: 5 surveys between 29 July and 10 September 1975; 4 surveys between 27 October 1975 and 1 December 1975; and 5 surveys between 23 October 1978 and 1 February 1979. In addition, 8 surveys between 18 October 1976 and 14 February 1977 had only 1 record -2 robins on 29 November 1976. The continuous periods of absence are significant considering the number of birds seen over the study and the overall high frequency of occurrence (67\%).

The Golden-crowned Kinglet was the second most abundant muscicapid, with a total of 249 birds seen. Seasonal totals for the whole study period were similar; the highest was autumn (29\%) and the lowest was spring (21\%), but the pattern changed. The Golden-crowned Kinglet was not seen from the end of November until 4 February. Then, from that time until 26 March, all 5 records were of 20 to 25 birds. For the remainder of the year most of the sightings involved only

1 bird each. The peaks for the summer-autumn period of each year were: 20 birds on 26 August 1975, 14 birds on 7 September 1977, 10 birds on 12 October 1976 and 12 birds on 23 October 1978. Thus the frequency of occurrence fluctuated from $10 \%$ in winter to $46 \%$ in autumn. The limited data of this study indicates that there was a gradual decline in the number of Golden-crowned Kinglets on the estuary from an average of 3.02 birds per survey in 1975 to 1.23 birds per survey in 1978.

We saw a total of 44 Ruby-crowned Kinglets: 18 birds in autumn (41\%), 10 birds in winter, 10 birds in spring and 6 birds in summer. This species is known to breed on Vancouver Island (Campbell et al. In prep.). Most of the sightings were of single birds but there were 2 notable peaks: 7 birds on 23 October 1978 and 5 birds on 22 July 1975. The frequency of occurrence was $17 \%$ over the study period.

The Swainson's Thrush tally was 135 birds in total; most of them were seen in summer (90\%). Earliest arrival occurred from 19 May (1977) to 27 May (1975) except in 1978 when the earliest arrival recorded was 19 June. Latest departure was from 29 July (1975) to 5 August (1977). From arrival to departure the species was noted on almost every survey; peaks were: 7 birds on 14 June 1976, 13 birds on 17 June 1977 and 6 birds on 22 July 1975.

We saw a total of 50 Varied Thrushes; most of the birds were seen in winter (44\%) and spring (42\%). From the earliest arrival on 1 October (1975) to the latest departure on 27 April (1979), the frequency of occurrence was $26 \%$. A peak of 13 birds was observed on 4 March 1976.

Two Hermit Thrushes were seen: 1 bird on 15 December 1975 and 1 bird on 30 March 1976.

We saw 2 Western Bluebirds on 30 March 1976.
One Mountain Bluebird'was recorded on the same survey as the Western Bluebirds - 30 March 1976.

Townsend's Solitaire was seen once, a single bird on 18 April 1977.
Pipits. The total number of American Pipits seen was 174 birds, most of the them in autumn (60\%) and spring (39\%). The spring migration was observed from 26 April (1976 and 1978) to 14 May (1979); the peaks were: 50 birds on 26 April 1978 and 12 birds on 3 May 1976. Records of the autumn migration were from 22 August (1977) to 23 November (1976); the southbound peaks were: 60 birds on 16 September 1975 and 34 birds on 27 September 1976.

Waxwings: The Cedar Waxwing total was 294 birds over the study period. The majority was seen in summer (77\%) and autumn (23\%). Earliest arrival was 2 birds on 25 May 1979 and the latest departure was 15 birds on 12 October 1976. Peaks were observed: 20 birds on 6 June 1977, 22 birds on 26 July 1977, 20 birds on 29 July 1975,22 birds on 3 August 1976 and 40 birds on 4 October 1976. The frequency of occurrence varied; in 1976 from 14 June to 12 October the Cedar waxwing was observed on $83 \%$ of 18 surveys, but in 1975 and 1977 it was seen on only 3 surveys and 1 survey respectively.

Shrikes: The Northern Shrike was seen 3 times over the study period: 1 bird on 4 October 1976, 1 bird just over a year later on 7 October 1977 and 1 bird on 20 March 1978.

Starlings. The gregarious European Starling was the most abundant passerine species with 9027 birds seen, $34 \%$ of the passerine total. Flocks of starlings could be seen at any time of the year on the Little Qualicum River estuary but the numbers were highest in autumn ( $50 \%$ of starlings) when a single survey counted 4000 birds on 7 September 1977. Apart from this startling spectacle, summer had the highest proportion ( $28 \%$ of starlings) with peaks: 600 birds on 30 August 1976, 308 birds on 5 August 1977, and 201 birds on 19 August 1975.

Vireos. Hutton's Vireo was recorded 4 times, 1 bird on each of the following surveys: 19 January 1975, 24 February 1975, 30 March 1976, 7 September 1977.

Wood Warblers, Sparrows and Blackbirds. The emberizids are a large and diverse group that ranked as the second most abundant passerine family with a total of 4954 birds ( $19 \%$ of all passerines). Eight species of warblers, 1 species of tanager, 12 species of sparrows and 4 species of blackbirds were recorded over the study. The sparrows were the most abundant of the subgroups in this family.

Warblers: The Orange-crowned Warbler was the most abundant of this sub-group with a total of 90 birds seen. Earliest arrival was 2 birds on 18 April 1977 and latest departure was 1 bird on 4 October 1976, but most of the birds were tallied in spring (60\%). The following peaks were noted: 9 birds on 25 April 1977, 17 birds on 10 May 1976 and 10 birds on 28 June 1976. The frequency of occurrence in summer varied from $8 \%$ in 1975 to $39 \%$ in 1976 and $33 \%$ in 1977.

A total of 77 Common Yellowthroats was seen, most of them in summer (68\%). The earliest arrival was 1 bird on 25 April 1977 and latest departure was 6 birds on 16 September 1975; during the summer the frequency of occurrence varied (from $8 \%$ in 1975 to $78 \%$ in 1977). The 2 highest numbers in the study were in August: 8 birds on 23 August 1976 and 7 birds on 5 August 1977.

We recorded 65 Yellow Warblers in total, most of them in summer (74\%). The earliest arrival was 1 bird on 27 April 1979 and the latest departure was 1 bird on 22 August 1977. Like several other warblers, the frequency of occurrence of the Yellow Warbler was sometimes high during the summer but not consistently so (from $78 \%$ in summer 1977 to $31 \%$ in summer 1975). The highest number on any survey was 7 birds on 5 August 1977 and second highest was 6 birds on 25 May 1979.

The number of Yellow-rumped Warblers recorded was also 65 birds in total, but this species was seen in larger numbers and less frequently than the Yellow Warbler; observations were of the spring and autumn migration. Earliest arrival was 14 birds on 12 April 1976 and the latest departure was 2 birds on 6 June 1978; there were no other records in summer. Other northbound peaks were: 9 birds on 25 April 1977 and 8 birds on 15 May 1975. There were only 2 records
from autumn; they accounted for almost half the Yellow-rumped Warblers seen: 25 birds on 7 October 1977 and 4 birds on 17 October 1977.

We saw a total of 52 Townsend's Warblers, all of them in the summer (62\%) and spring (32\%). Earliest arrival was 4 birds on 25 April 1977 and latest departure was 1 bird on 23 August 1976. Other peaks were: 5 birds on 17 August 1976 and 4 birds on 25 May 1979. During the summer the frequency of occurrence varied from $77 \%$ in 1976 to $33 \%$ in 1977; the species was not seen at all in 1975.

The total number of Wilson's Warblers counted was also 52 birds. The species was reported in every year surveyed but each year was different; most of the Wilson's Warblers were seen in 1976 when the earliest arrival was recorded: 1 bird on 3 May (1976). The following week the peak of 16 birds was observed (10 May 1976) on their migration; the latest spring departure that year was 4 birds on 25 May 1976. The next period when the species was seen in 1976 was from 28 June until 9 August. In 1977, the species was seen occasionally from 12 May through the likely breeding period in June to 15 July. The only Wilson's Warbler seen in 1975 was a single bird on 2 September 1975. Latest departure in 1976 and 1977 was similar to the record from 1975: 1 bird on 20 September 1976 and 1 bird on 7 September 1977. Peaks not mentioned above include: 5 birds on 25 May 1979 and 5 birds on 17 June 1977.

During the surveys, 24 MacGillivray's Warblers were recorded in total. Earliest arrival was 7 birds seen on 10 May 1976 and latest departure was 1 bird on 27 September 1977. The species was most abundant in 1976; birds occurred in every month from May to September except June. However, there this warbler was observed in June of 1975 and 1977.

One Black-throated Gray Warbler was recorded on 20 September 1976.
Tanagers: The Western Tanager was recorded once: 6 birds on 20 May 1975.

Sparrows: The Dark-eyed Junco was the most abundant sparrow with a total of 1025 birds seen; most of them in winter (46\%) and autumn (38\%). The earliest arrival was on 8 October in 1975, 27 September 1976 and 26 September 1977. The latest departure also advanced by a few days over those same years: 22 April 1975, 20 April 1976 and 4 April 1977. The species occurred on almost every survey in autumn but in winter the frequency of occurrence varied from zero (1975 and 1978) to $92 \%$ (1976); this indicates that the Dark-eyed Junco must have at least one alternative to wintering on the Little Qualicum estuary. Nevertheless, in 1975, 1976, 1977 and 1979 the number of birds on the estuary appeared to reach a peak some time in late autumn or winter; all 7 of the surveys which recorded 30 or more birds occurred in the period from 17 November to 4 February of those 4 years. The maximum one-day count was 64 birds on 15 December 1975. Juncos were seen in every spring surveyed but occurrence was not as frequent as in autumn.

The Song Sparrow, with a total of 613 birds tallied, was the second most abundant sparrow observed. The seasonal total of this resident was highest in summer (31\%) and lowest in winter (18\%) but the frequency of occurrence was high in every season surveyed (approximately $90 \%$ overall). Similarly, the yearly
peaks were not confined to any season: 15 birds on 15 December 1975, 12 birds on 5 July 1976, 19 birds on 15 July 1977, 8 birds on 20 March 1978 and 8 birds again on 6 June 1978 and finally, 9 birds on 5 May 1979.

The third most numerous sparrow was the Savannah Sparrows; we saw a total of 396 birds, most of them in autumn (60\%) and spring (27\%). The start of the spring migration was well defined; every year the earliest arrival occurred from 18 April (1977) to 27 April (1979). Spring peaks were recorded: 11 birds on 15 May 1975, 21 birds on 10 May 1976, 7 birds on 25 April 1977 and 15 birds on 26 April 1978. In 1975 and 1976 the species was not seen from 27 May to 26 July but in 1977 and 1978 we have 4 records of 1 or 2 birds through the June to mid July period. Numbers and frequency of occurrence increased again through August until the following peaks were observed: 18 birds on 10 September 1975, 35 birds on 20 September 1976 and 37 birds on 19 September 1977. The latest departure was 1 bird on 10 November 1975.

A total of 380 Golden-crowned Sparrows were recorded. The species was most abundant in winter ( $38 \%$ of the total); the proportions seen in autumn and spring were equivalent. The only summer record was 3 birds on 19 August 1975, separated from any other sighting. Earliest arrival occurred in the period from 19 September to 20 October and the latest departure occurred from 26 April to 15 May. Peaks in the numbers of Golden-crowned Sparrows were recorded in various seasons: 21 birds on 15 May 1975, 16 birds on 18 October 1976, 12 birds on 26 September 1977 and 12 birds again on 19 December 1977, and 12 birds on 25 January 1979. The frequency of occurrence in winter was usually high (above $67 \%$ ).

We saw 372 Rufous-sided Towhees in total. Although this species is a resident, the numbers seen varied with the season; most were seen in autumn ( $40 \%$ ) and winter ( $33 \%$ ). The lowest seasonal totals were tallied in summer (11\%) as many of the wintering birds dispersed to their breeding areas. The proportion of surveys that recorded this species varied with the seasons, predictably following the same pattern as the seasonal totals except in winter when the frequency of occurrence was often low ( $50 \%$ in 1977 and 1978). Further study would be required to determine if overwintering birds were sometimes using areas other than the estuary.

Over the study period, we recorded 144 White-crowned Sparrows in total. They were observed in every season but most occurred in spring (51\%). The lowest seasonal total was the sum of 14 birds counted in the winters of 1975-1976 and 1978-1979; the other 3 winters of the study recorded no White-crowned Sparrows. The 3 highest records in this study were: 15 birds on 3 May 1976, 9 birds on 6 September 1976 and 8 birds on 25 January 1979. Frequency of occurrence within each year was variable but a comparison of spring seasons over the years of study shows relative constance (from $50 \%$ in 1977 to $100 \%$ in 1978).

A total of 74 Fox Sparrows was seen, most of them in autumn (53\%) and winter (30\%); the species was not seen in summer. Earliest arrival occurred in the period from 20 September to 20 October. Latest departure occurred from 30 March to 25 April excluding 1978 and 1979 when no birds were seen in the spring. The only surveys with more than 3 Fox Sparrows were: 16 birds on 27 October 1975 and 4 birds on 4 October 1976.

On the surveys, a total of 48 Lincoln's Sparrows were recorded passing through on their migrations. Spring records were: 2 birds on 25 April 1977, 1 bird on 27 April 1979, 2 birds on 10 May 1976 and 1 bird on 17 May 1976. Records of the southbound migration tallied 42 birds from the earliest arrival of 2 birds on 29 August 1977 to the latest departure of 2 birds on 12 October 1976. The peaks recorded were: 11 birds on 20 September 1976, 8 birds on 26 September 1977 and 6 birds on 1 October 1975.

Five Chipping Sparrows were seen: 3 birds on 3 May 1976 and 2 birds 2 weeks later on 17 May 1976.

We recorded 2 American Tree Sparrows: 1 bird on 25 January 1978 and 1 bird 2 weeks later on 1 February 1978.

One White-throated Sparrow was seen on 7 October 1977.
The Snow Bunting was seen once: a single bird on 21 November 1977.
Blackbirds: The most abundant of this group was the Brewer's Blackbird with a total of 834 individuals seen, most of them in summer (87\%). Earliest arrival each year occurred from 20 March to 5 April except in 1979 when the only Brewer's Blackbird seen was on 25 May 1979. The largest number recorded on the spring migration was 20 birds on 26 March 1975; all other spring records were of 6 birds or less. The latest departure was in October except in 1977 when no birds were seen in autumn. The peak number of each year occurred in summer: 63 birds on 17 June 1975, 73 birds on 26 July 1976, 39 birds on 5 August 1977 and 11 birds on 17 July 1978. The frequency of occurrence in summer was relatively constant, dropping from $85 \%$ to $67 \%$ from 1975 to 1978 but in the same period the average number of Brewer's Blackbirds seen per survey dropped steadily from 8.7 through 6.2 and 4.3 to 1.8 birds per survey in 1978.

The Red-winged Blackbird was the second most abundant of the blackbirds; a total of 524 birds was tallied over the study, most of them in summer (48\%) and spring (47\%). From the earliest arrival on or after 12 February each year, the species was present on the estuary almost continuously until sometime in July. The peak number of the year was often recorded shortly before the majority of the blackbirds left the area: 27 birds on 14 July 1975, 23 birds on 21 June 1976 and 34 birds on 27 June 1977. Thereafter, low numbers of birds continued to be seen sporadically in some years (1976 and 1977). The only records of the species in the September to January period are from 1977-1978, suggesting that a few blackbirds left very late or overwintered on the estuary that season: 7 birds 26 September 1977, 1 bird on 7 October 1977 and 2 birds on 19 December 1977.

A total of 62 Brown-headed Cowbirds was reported over the study period, most of them in spring (79\%). The earliest arrival was 6 birds on 25 April 1977 and the latest departure was 3 birds on 12 July 1976. Other surveys with high counts were: 27 birds on 27 April 1979, 4 birds on 20 May 1975 and 4 birds on 7 July 1977.

During the surveys, a total of 39 Western Meadowlarks were counted, most of them in winter (49\%) and autumn (41\%). Earliest arrival was 2 birds 23 October (1978) and latest departure was 1 bird on 20 April (1976). The most meadowlarks seen on a single survey was 4 birds on 1 December 1975.

Finches: Seven species of finches were recorded over the study period with a combined total of 2849 birds. The Pine Siskin was the most abundant finch with a total of 1255 birds seen over the study period. They were present in all seasons but the largest numbers were in winter (55\%) and autumn (37\%). Nevertheless the frequency of occurrence was often relatively low (50\% or less) because the bird sometimes forms huge flocks. Described as nomadic in fall and winter and an irruptive species by Ehrlich (1988), the Pine Siskin can be unpredictably observed at any time of year. This is illustrated by a list of the largest numbers reported in each year: 220 birds on 24 November 1975, 240 birds on 4 February 1976, 100 birds on 19 January 1977, 20 birds on 23 November 1978 and 80 birds on 13 December 1979.

The American Goldfinch, with a total of 598 birds seen, ranked second in abundance among the finches. Most of the birds ( $80 \%$ ) were seen in summer. The earliest arrival occurred in the period from 25 April (1977) to 15 May (1975). The latest departure in each year surveyed was: 16 September 1975, 19 September 1977 and 12 October 1978. The year 1978 was unusual in that there was only 2 records for the American Goldfinch: 6 birds on 6 June 1978 and 8 birds on 19 June 1978. In most years the frequency of occurrence ranged from $85 \%$ to $100 \%$ in summer when the peak number of each year was observed in the first 3 weeks of August: 43 birds on 19 August 1975, 106 birds on 17 August 1976 and 75 birds on 5 August 1977.

The House Finch was the third most abundant of the finches with a total of 504 birds tallied. It was common in spring and summer but most of the birds were seen in autumn ( $43 \%$ ) and winter ( $26 \%$ ). The frequency of occurrence was relatively constant through the seasons but it varied through the years surveyed: in 1975 it was approximately $40 \%$, in 1976 and 1977 it had climbed to almost $65 \%$, in 1978 and 1979 it had fallen back to around $50 \%$. The peak number in each of the years fully surveyed occurred in October or November: 23 birds on 20 October 1975, 25 birds on 31 October 1977 and 25 birds again on 21 November 1977, 22 birds on 23 November 1976 and 35 birds on 23 November 1978.

We saw a total of 302 Red Crossbills. They were seen in every month of the year except November and December but most of the birds in this study (76\%) occurred in the summer of 1976; a number of crossbills (up to a maximum of 49 birds) was seen on every survey from 12 July 1976 to 6 September 1976. Sightings of crossbills are variable (Ehrlich 1988) because these birds depend heavily on coniferous cone crop levels. The species was not seen in 1975 and then after the eruption of 1976, the numbers declined steadily over the years until only 1 Red Crossbill was seen in 1979.

During the surveys a total of 121 Evening Grosbeaks were recorded, most of them in spring (52\%). The species was not seen in summer. Earliest arrival occurred from 26 September to 20 October and the latest departure was in April or May. This bird's use of the estuary was not consistent; in 1975 they were seen in winter but not spring; in 1977 they were seen in spring but not winter and in 1978 and 1979 only 1 bird was seen each year (in spring). The peak numbers were: 20 birds on 19 January 1975, 13 birds on 12 February 1976 and 35 birds on 3 March 1977.

We saw a total of 66 Purple Finches. The species was seen in every season with the largest proportion seen in autumn (38\%) and the smallest in summer
(12\%); the species was not observed in the period between 11 June to 26 September. The highest number recorded in a single survey was 10 birds on 12 October 1976. The frequency of occurrence was below $25 \%$.

The Pine Grosbeak was sighted once, 3 birds on 23 October 1978.
Weaver Finches: This group is represented by the introduced House Sparrow; we saw 30 in total over the spring ( 12 birds), summer ( 11 birds) and autumn ( 7 birds). The largest numbers seen on 1 survey were 8 birds o 3 August 1976 and 7 birds on 20 October 1975.

## Conclusions

## Bird Use and Recreational Activities

The Little Qualicum River estuary is an important area for migratory and resident birds through the seasons. Because the site is within the MarshallStevenson Unit of the Qualicum National Wildlife Area, it does not receive the same degree of disturbances noted on the Cluxewe River estuary (see Dawe et. al. 1995), the Campbell River estuary (Dawe et al. in preparation) and some of the other estuaries along the east coast of Vancouver Island. Recreational access is restricted in order for the area to approach its full potential in terms of supporting numbers of birds. Perhaps as a result of this and other factors, the minimum numbers of birds dependent on the estuary of the Little Qualicum are several times higher than the minimum numbers of birds dependent on the Cluxewe or Campbell River estuaries. Bird use on the nearby Englishman River estuary with 170 hectares of floodplain is similar to bird use on the Little Qualicum even though the Little Qualicum River estuary is much smaller (approximately 50 hectares). If the numbers of gulls that arrive with the herring spawn are omitted because of the short time span, the variable size of this resource and the hit-or-miss nature of the surveys with respect to it, then the comparison between the two neighbouring rivers is even more striking.

The Regional District of Nanaimo predicts substantial population growth in the area. Although the present status of the property protects it from urbanization and recreational use, increases in population of the surrounding areas might result in increasing pressure for public access. Any changes to access should be considered carefully with regard to the impact on bird use.

## Future Studies

Baseline studies such as this one should be compared to similar studies in the future as part of an effort to monitor the effects of urbanization and other human influences that are increasing in the region are having on the migratory birds resource.

Since estuaries are dependent on the inflow of water from the river and the presence of a high water table, any changes that might affect the flow in the Little Qualicum River should involve further study of its impact on the estuary and its bird life.

Carduelis tristis
Coccothraustes vespertinus
Passer domesticus

## Appendix IV.

Little Qualicum River estuary birds surveys: Seasonal bird numbers, 19 January 1975 through 25 May 1979.

Note: In this Appendix, the mean has been calculated as the total number of birds of species-x counted over the season, divided by the total number of counts where species-x occurred. Counts of zero have not been included in the total number of counts nor are they included as minimum values. Thus the last 5 columns in the Appendix summarize the species occurrence on the study area. For example, the probability of seeing a Black Scoter in the winter of 1974-1975 on the Little Qualicum River estuary was about $67 \%$. If you see the species, you are likely to see an average of about 35 birds and more than 46 would be exceptional.

Bird surveys of Little Qualicun River estuary for Winter 1974-1975.
