## **TECHNICAL REPORT SERIES CANADIAN WILDLIFE SERVICE**

These reports contain technical and scientific information from projects of the Canadian Wildlife Service. They are intended to make available material that either is of interest to a limited audience, or is too extensive to be accommodated in scientific journals or in existing CWS series.

Demand for these Technical Reports is usually confined to specialists in the fields concerned. Consequently they are produced regionally and in small quantities; they can be obtained only from the address given on the title page. However, they are numbered nationally. The recommended citation appears on the back of the title page.

Technical Reports are available in CWS libraries and are listed with the DOBIS system in major scientific libraries across Canada. They are printed in the official language of the author's choice.

## **SÉRIE DE RAPPORTS TECHNIQUES DU SERVICE CANADIEN DE LA FAUNE**

Ces rapports donnent des informations scientifiques et techniques sur les projets du Service canadien de la faune (SCF). Ils visent à promouvoir la diffusion d'études s'adressant à un public restreint ou trop volumineuses pour paraître dans une revue scientifique ou une des séries du SCF.

Ordinairement, les demandes pour ces rapports techniques ne proviennent que de spécialistes des sujets traités. Ils ne sont donc produits qu'à l'échelon régional et en quantités limitées; leur numérotage est cependant effectué à l'échelle nationale. Ils ne peuvent être obtenus qu'à l'adresse figurant à la page titre. La citation recommandée apparaît au verso de la page titre.

Ces rapports se trouvent dans les bibliothèques du SCF et figurent aussi dans les listes du système de référence DOBIS utilisé dans les principales bibliothèques scientifiques du Canada. Ils sont publiés dans la langue officielle du choix de l'auteur.

*Cover illustrations for all regions are by R.W. Butler. These illustrations may not be used for any other purpose without the artist's written permission.*

*L'illustration sur la couverture (spécifique à chaque région) est une œuvre de R.W. Butler. Ces illustrations ne peuvent être utilisées d'aucune autre façon sans la permission expresse de l'auteur.*

ABSTRACT

To determine the effect of impounding stormwater within an area of the Cattermole Creek intertidal marsh, Squamish River estuary, baseline vegetation data were gathered from the marsh in September 1984.

Three permanent transects were established across the marsh and from a total of 100 relevés, 26 species of vascular plants were recorded. Carex lyngbyei, Potentilla pacifica, Triglochin maritimum, and Deschampsia cespitosa dominated the vegetation. Four intertidal plant communities were identified within the study area and are described along with elevation and soilwater salinity data.

Requirements for a five year monitoring program of the marsh are also discussed.

RESUME

Afin de déterminer l'effet de l'endiguement des eaux d'évacuation (à ciel ouvert) dans un certain secteur du marais intertidal, de Cattermole Creek, dans l'estuaire de la rivière Squamish, on a relevé des données sur la végétation du marais, en septembre 1984.

On établi trois transects permanents dans le marais. Sur le total de 100 relevés, on a enregistré 26 espèces de plantes vasculaires. Les plantes dominantes étaient: Carex lyngbyei, Potentilla pacifica, Triglochin maritimum et Deschampsia cespitosa. On a identifié quatre groupes de plantes intertidales à l'intérieur du secteur étudié. L'étude comprend la description de ces plantes ainsi que des données sur la profondeur et la salinité de l'eau absorbée par le sol.

La rapport examine aussi les besoins justifiant un programme d'étude de 5 ans portant sur le marais.

ACKNOWLEDGEMENTS

Field assistance was provided by Bruce Cox and Jacques Sirois. Elevation data were gathered by Gilbert Bradshaw with assistance from a Fisheries Resource Employment Development for Youth crew, Larry Delmistro, Job Coordinator. Kevin Conlin, Bob McIndoe, and the District of Squamish provided logistical support. F.E. Stephenson and T. Ma, Institute of Ocean Sciences, provided the tidal inundation data for Pt. Atkinson, and instructions which enabled a conversion to Cattermole Creek marsh elevations. John Smith commented on the statistical analysis. Sean Boyd and Laszlo Retfalvi reviewed the manuscript. Susan Garnham typed the manuscript.

## INTRODUCTION

The community of Squamish is located near the Squamish River estuary at the head of Howe Sound (Figure 1). The downtown core, located on the low-lying estuarine floodplain of the river, has required flood protection by dykes and drainage works. Despite those measures, frequent heavy rains in the area have often combined with high tides to cause flooding.

To help relieve that problem, the District of Squamish began planning in early 1982 for the creation of a controllable stormwater impoundment area. The area would be used to store excess runoff during periods of heavy rain where high tidal conditions would otherwise preclude gravity run-off from within the dyke. The site selected was an area of intertidal marsh in the Cattermole Creek basin (Figure 1).

## PROJECT DESCRIPTION

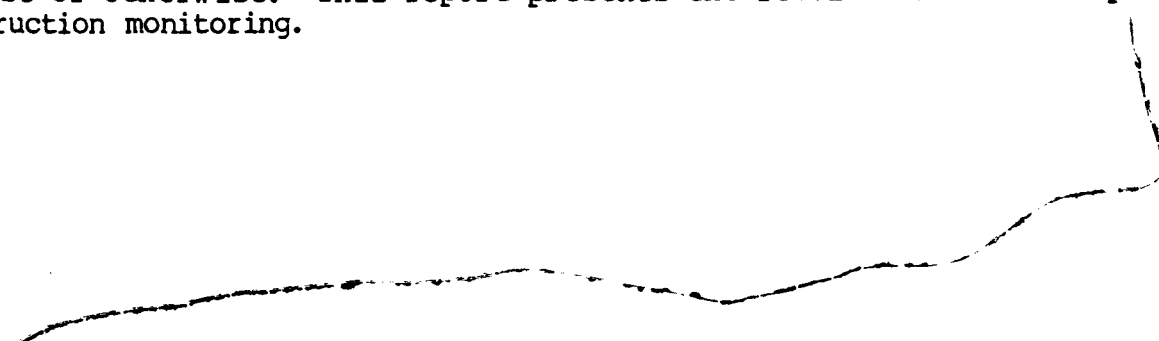

The proposal involved the installation of a flood gate on upper Cattermole Creek at a point immediately upstream of the Third Avenue Bridge over the creek (Figure 2). The floodgate would only be closed when the threat of flooding was imminent. Otherwise, it would remain open and normal tidal flushing of the basin would occur. The floodgate would have flap valves to allow drainage of the basin, but would prevent water from passing upstream into the impoundment area on a rising tide. Closure of the gate would prevent tidal inundation of the upstream area, leaving it available for use as a stormwater impoundment area. The flap valves would open on a falling tide to allow the stormwater to drain, after which the above-described cycle could repeat. Construction of the system took place in the fall of 1984, and it is now in use (Appendix 8).

## NEED FOR THE PRESENT STUDY

Upon review of the above-described proposal by resource agencies (Environment Canada, Dept. of Fisheries and Oceans, B.C. Ministry of Environment), it was agreed that a change in the character of the intertidal marsh in the impoundment area could occur.

A number of operational constraints were discussed between the resource agencies and the District of Squamish. The need to monitor effects on the marsh was identified. Unfortunately, the District did not budget for the necessary pre-construction monitoring. Instead, it proceeded with final design and tendering for the work in the summer of 1984.

Negotiation with the District resulted in an agreement that the resource agencies would conduct the pre-construction monitoring in 1984, with the District assuming responsibility for post-construction monitoring in 1985 and future years. That monitoring would continue for as long as necessary (to a maximum of five years) to demonstrate water impoundment effects on the marsh, adverse or otherwise. This report presents the results of the 1984 pre-construction monitoring.

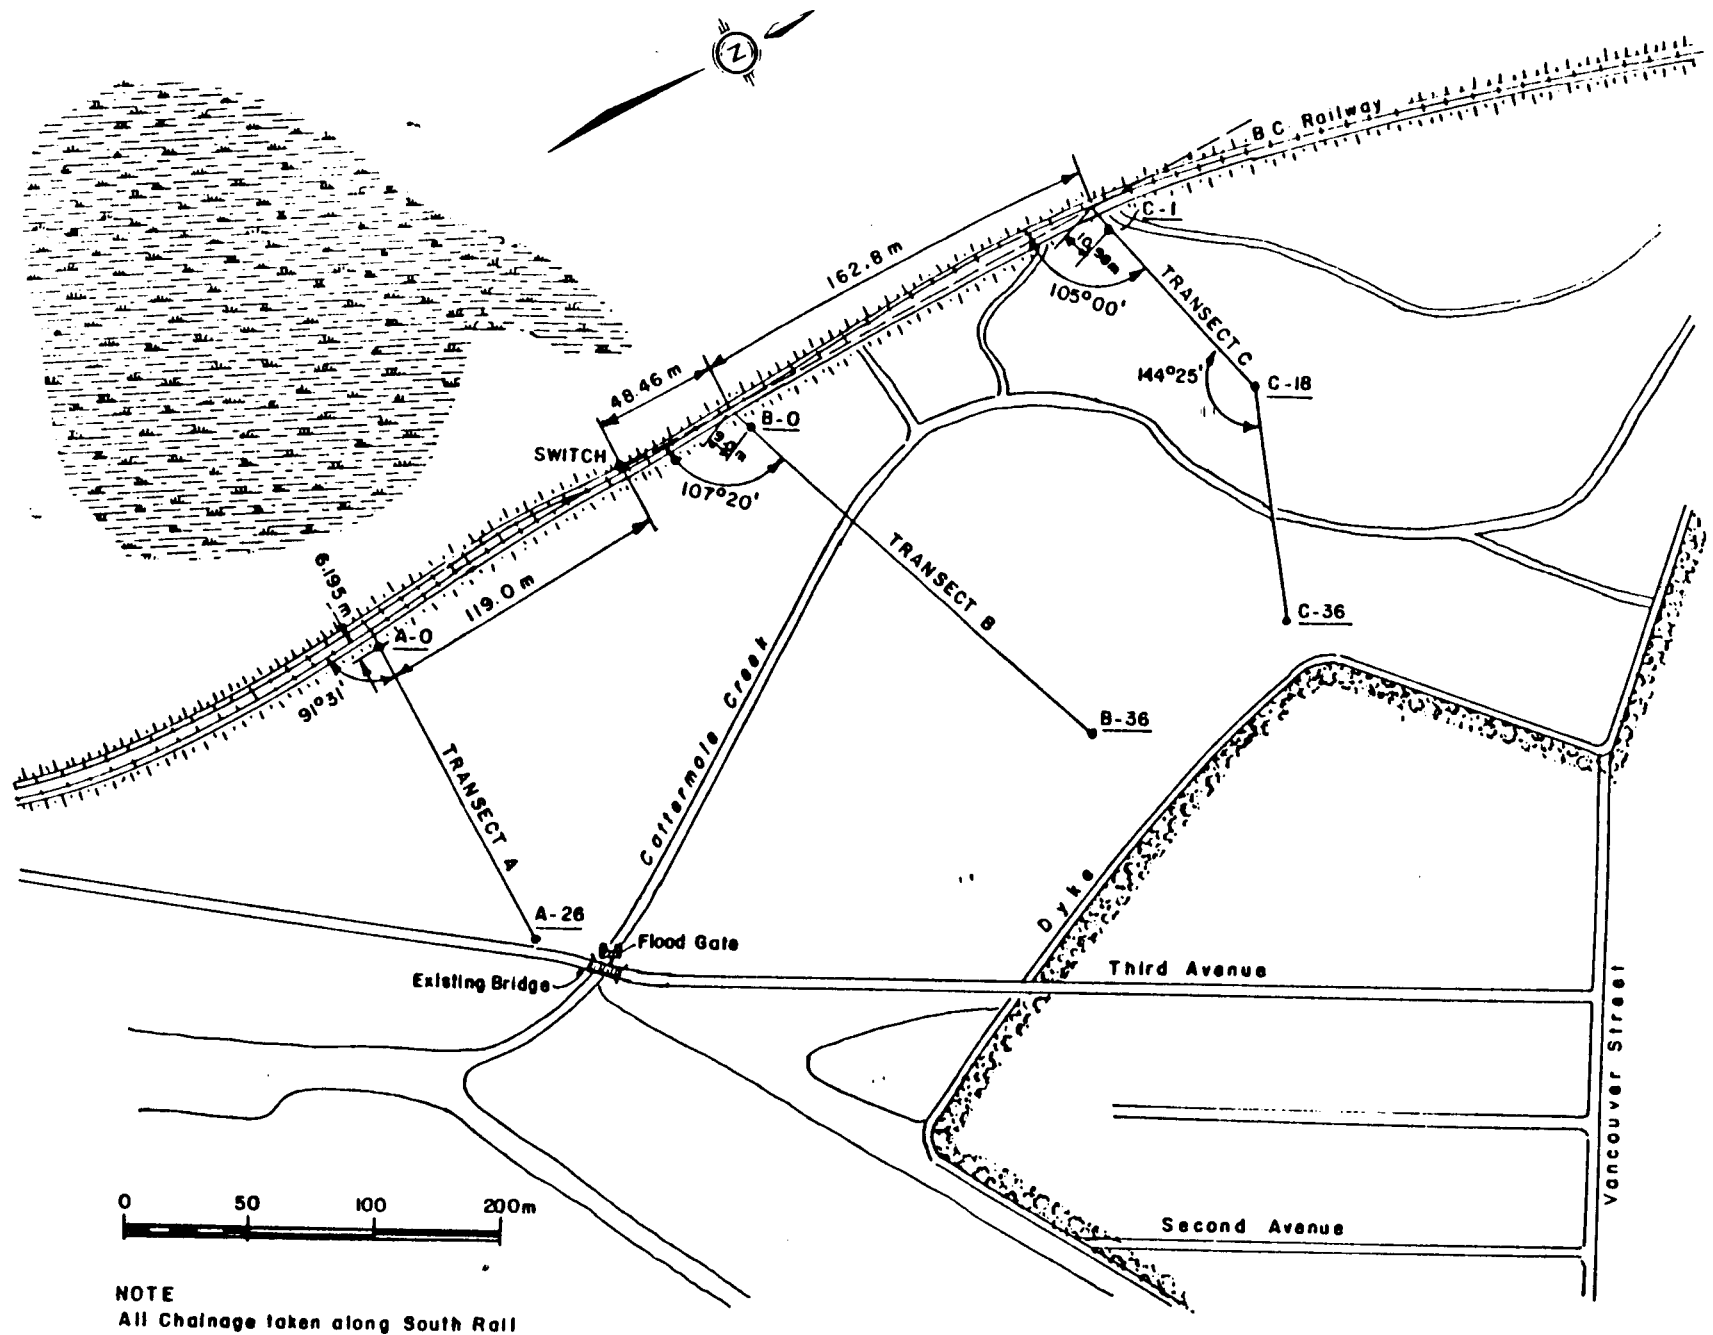

Figure 2. District of Squamish flood control basin. Locations of vegetation survey transects, 25 September 1984.

## LOCATION AND DESCRIPTION OF THE STUDY AREA

The Cattermole Creek marsh (about 8 ha) is located on the east delta of the Squamish River estuary (Figure 1). The creek is a former dendritic tidal channel that was cut off from the rest of the estuary by the British Columbia Railway rail line in 1972. However, tidal inundation still occurs. The east side of the marsh is bounded by a dyke which protects the Town of Squamish from tidal flooding. Qualitative descriptions of the estuary in general have been summarized by the Habitat Work Group (1981).

## METHODS

On 25 September 1984, three vegetation transects were established across the Cattermole Creek marsh to cover the low, intermediate and high elevations of the marsh platform (Figure 2 and Appendix 8). Wooden stakes were driven at 5 m intervals along the transects to denote the center of each releve (or vegetation sample). All vascular plant species within a 1 m<sup>2</sup> releve were identified and recorded (see Dawe and White, 1982). Nomenclature follows that of Hitchcock and Cronquist (1973). Because the study was conducted well beyond the normal growth and flowering period of many of the plants, some species were difficult to identify and have only been taken to genera or family. The relative cover of each species was determined using the Braun-Blanquet cover abundance scale (Appendix 1). Substrate elevation data were also taken at the center of each releve. Care was taken to ensure that survey-related disturbance to the vegetation communities was minimized.

Data were analysed using the reciprocal averaging multivariate technique described by Orloci (1978). That method has a dual purpose: a single application results in the ordination of both samples (relevés) and species in terms of best fit of one to the other. Species with similar site distribution and sites with similar species composition are related independent of species abundance or site richness (Pimintel 1979). Analysis was carried out using the computer program RQT (Orloci 1978) on an Apple II+ microcomputer. Species with frequencies  $\leq 5\%$  were excluded from analysis. Frequency of occurrence was calculated by summing the number of occurrences of a species within a dataset and dividing that by the total number of possible occurrences within the dataset. Best estimates of mean cover/abundance for each species were calculated by summing the midpoint of each Braun-Blanquet scale range (ie. by setting  $r=.01$ ,  $+=.05$ ,  $1=3$ ,  $2=15$ ,  $3=37.5$ ,  $4=67.5$ ,  $5=87.5$ ) and dividing by the number of occurrences of the species within the dataset. Species and releve scores were plotted on scatter diagrams. Product moment correlations of the first three releve ordination axes with elevation data were calculated.

Tidal inundation ratios were calculated using the 1983 predicted tides for Point Atkinson. Those predicted tides were converted to local chart datum based on differences between Point Atkinson tides and those of the secondary port at Squamish. The year 1983 was chosen for the prediction set as it represents an approximately average year in the 18.6 year tidal cycle (Fred Stephenson, personal communication). Geodetic elevations were converted to chart datum by adding to them the mean water level at Squamish taken from Anonymous (1984).

Samples of soil water salinity were taken by squeezing a drop of water from a small soil sample onto an American Optical hand refractometer and reading the value directly.

## RESULTS

From 100 relevés a total of 26 species of vascular plants was recorded (Appendix 2). Of those species, four dominated the flora, occurring with frequencies of 20% or more. Carex lyngbyei occurred with the highest frequency and mean cover overall, followed by Potentilla pacifica, Triglochin maritimum, and Deschampsia cespitosa (Table 1). Cover/abundance data for species within transects is given in Appendices 3 and 4.

Canonical correlations for the first three sets of species scores and releve scores are high (Appendix 5) suggesting that the reliability of the species scores as ordering criteria is high (Orloci 1978). Seventy-five percent of the total chi square was accounted for by the first three canonical variates. Species scores were plotted on a three-dimensional scatter diagram to show their relationships with one another (Figure 3). Four species clusters are apparent (A-D), and allow the interpretation of the three-dimensional scatter diagram of the releve scores (Figure 4). For example, group AJ in Figure 4 is dominated by those species in cluster A of Figure 3.

Figure 4 suggests four major clusters (AJ, CP, C, R) which we have considered as vegetation communities. Table 2 shows the communities and their component species. Product moment correlation of releve elevations with axis I releve scores gives a correlation coefficient of  $r = -0.69$  ( $p < 0.001$ ), which suggests that the communities are good indicators of elevation. Axis I, Figure 4, could also then be interpreted as decreasing in elevation from 0 to 1.

Elevation data are shown in Appendix 7 and have been summarized in Figure 5 and Table 3. Table 3 gives ranges and mean elevations of vegetation communities for each transect and for all data combined. Mean inundating water ratios per 24h day and daylight hours for each community are also shown. Because Carex lyngbyei grows well at lower elevations on channel edges, we have separated those elevations from the major Carex-flats community. Ruppia maritima too, can grow at a broad range of elevations where standing water occurs, therefore Ruppia has been excluded from the Table.

Salinity of the soil water ranged from 0‰ to 11‰. Water salinity of Cattermole Creek was 5‰ at transect C and 8‰ near the end of transect A.

## DISCUSSION

Since the purpose of this study was to provide baseline data to measure changes in the vegetation of the Cattermole Creek marsh, little discussion is necessary. We would, however, like to make two points.

Firstly, vegetation of the Cattermole Creek marsh is similar to that of other brackish marshes in the Pacific Northwest (Dawe and White 1982, Eilers 1975). However, the Cattermole Creek marsh differs somewhat in that its pure stands of Carex are extensive and are not just restricted to edges of tidal channels. Carex lyngbyei is one of the most important vegetative components of our coastal marshes. It grows best under brackish conditions such as those found on the Cattermole Creek marsh, but can also grow under relatively fresh or saline conditions. Under the two latter conditions, however, its productivity seems to decrease (Dawe and White, in press). It is the most productive of our estuarine vascular plants with above-ground biomass estimates at Squamish of 1322 g dry wt/m<sup>2</sup> (Levings and Moody 1976). Carex also produces large numbers of seeds which form an important part of the diet of many estuarine animals, notably waterfowl and songbirds. Perhaps the most important feature of Carex, aside from its high productivity, is its characteristic of breaking down rapidly. Eilers (1975) found that Carex litter in May could be exhausted in as little as six days, while a community of Juncus or Agrostis could take over 300 days. Once broken down into tiny particles, Carex becomes available to the scores of detritivores such as amphipods, isopods, and clams that serve as food to higher vertebrates such as birds and fish. Based on Levings and Moody's (1976) data we estimated that Cattermole Creek marsh produces about 75 tonnes of Carex lyngbyei dry weight per year. Loss of that detrital input could have a negative impact on the overall productivity of the estuary.

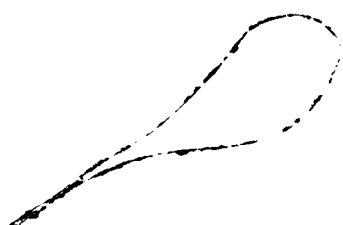

Secondly, the location of communities within the estuarine marsh seems to be governed mainly by the elevation of the marsh platform which, in turn, determines the degree of inundation and exposure that the marsh plants must undergo (Dawe and White 1982). In the case of Cattermole marsh, changes in inundation periods could cause a change in the vegetation composition of a community which, in turn, could affect the overall productivity of the estuary.

To determine changes such as those discussed above, the following activities are required.

- 1) The vegetation survey should be repeated annually, about the first two weeks in July, for at least the next five years (1985-1989). Soil water salinity measurements at each releve should also be gathered during the vegetation survey.
- 2) Surface and bottom measurements of the salinity of the inundating water should be obtained from at least three sites (ends and channels) along each transect during a high tide, preferably four times throughout the spring and summer (March, May, July and September).

- 3) Above-ground biomass estimates should be obtained each year, about the first two weeks in July, to compare the Carex productivity of the Cattermole marsh with that of a similar, adjacent "natural" marsh. That could most easily be accomplished by surveying a linear control transect on the west side of the B.C. Rail embankment and staking 36 releve locations at 5m intervals along the transect. The geodetic elevation of each releve centre should be determined. Within each 1m<sup>2</sup> releve on the control transect and on Transect B, within the Cattermole basin, record the releve number and measure the above-ground length of the tallest Carex plant to the nearest 0.5cm. The plant should be measured from the ground, adjacent to the plant stem, to the end of the longest leaf, including the brownish tip.
- 4) A water guage should be installed inside the Cattermole Creek basin to record automatically the tidal elevations and durations, so that differences in inundation periods from the norm can be calculated.

APPENDICES

APPENDIX 1

Braun-Blanquet cover-abundance scale  
(from Mueller-Dombois and Ellenberg 1974)

---

- 5 - any number, with cover > 75%
- 4 - any number, with cover of 51% - 75%
- 3 - any number, with cover of 26% - 50%
- 2 - any number, with cover of 6% - 25%
- 1 - numerous, with cover of 1% - 5%
- + - few, with small cover (<1%)
- R - solitary, with small cover

APPENDIX 2

Vascular plant species list compiled from all releves within the Cattermole Creek marsh, Squamish River estuary, September 1984.

Acronym	Species
1 CARX LYNG	<u>Carex lyngbyei</u> Hornem.
2 POTE PACI	<u>Potentilla pacifica</u> Howell
3 TRIG MARI	<u>Triglochin maritimum</u> L.
4 DESC CESP	<u>Deschampsia cespitosa</u> (L.) Beauv.
5 JUNC BALT	<u>Juncus balticus</u> Willd.
6 RUPP MARI	<u>Ruppia maritima</u> L.
7 AGRO ALBA	<u>Agrostis alba</u> L.
8 SONC ARVE	<u>Sonchus arvensis</u> L.
9 DAUC SP ?	<u>Daucus</u> species?
10 HORD BRAC	<u>Hordeum brachyantherum</u> Neusk.
11 ASTR SPEC	<u>Aster</u> species
12 LEGU SPEC	Leguminosae species
13 UMBL SPEC	Umbelliferae species
14 LILA OCCI	<u>Lilaeopsis occidentalis</u> Coult. & Rose.
15 RANU CYMB	<u>Ranunculus cymbalaria</u> Pursh
16 PLAN MARI	<u>Plantago maritima</u> L.
17 ACHI MILL	<u>Achillea millefolium</u> L.
18 PLAN MACR	<u>Plantago macrocarpa</u> Cham & Schlecht
19 SIDA HEND	<u>Sidalcea hendersonii</u> Wats.
20 ELEO PALU	<u>Eleocharis palustris</u> (L.) R. & S.
21 STEL HEMI	<u>Stellaria hemifusa</u> Rottb.
22 OENA SP ?	<u>Oenanthe</u> species?
23 MIAN DILA	<u>Mianthemum dilatatum</u> (Wood) Nels. & Macbr.
24 SIUM SUAV	<u>Sium suave</u> Walt.
25 FRIT CAMS	<u>Fritillaria camschatcensis</u> (L.) Ker-Gawl
26 TRIF WORM	<u>Trifolium wormskjoldii</u> Lehm.
