# TECHNICAL REPORT SERIES CANADIAN WILDLIFE SERVICE

This series of reports, established in 1986, contains technical and scientific information from projects of the Canadian Wildlife Service. The reports are intended to make available material that either is of interest to a limited audience or is too extensive to be accommodated in scientific journals or in existing CWS series.

Demand for these Technical Reports is usually confined to specialists in the fields concerned. Consequently, they are produced regionally and in small quantities; they can be obtained only from the address given on the back of the title page. However, they are numbered nationally. The recommended citation appears on the title page.

Technical Reports are available in CWS libraries and are listed with the DOBIS system in major scientific libraries across Canada. They are printed in the official language chosen by the author to meet the language preference of the likely audience. To determine whether there is significant demand for making the reports available in the second official language, CWS invites users to specify their official language preference. Requests for Technical Reports in the second official language should be sent to the address on the back of the title page.

#### SÉRIE DE RAPPORTS TECHNIQUES DU SERVICE CANADIEN DE LA FAUNE

Cette série de rapports donnant des informations scientifiques et techniques sur les projets du Service canadien de la faune (SCF) a démarré en 1986. L'objet de ces rapports est de promouvoir la diffusion d'études s'adressant à un public restreint ou trop volumineuses pour paraître dans une revue scientifique ou l'une des séries du SCF.

Ordinairement, seuls les spécialistes des sujets traités demandent ces rapports techniques. Ces documents ne sont donc produits qu'à l'échelon régional et en quantités limitées; ils ne peuvent être obtenus qu'à l'adresse figurant au dos de la page titre. Cependant, leur numérotage est effectué à l'échelle nationale. La citation recommandée apparaît à la page titre.

Ces rapports se trouvent dans les bibliothèques du SCF et figurent aussi dans les listes du système de référence DOBIS utilisé dans les principales bibliothèques scientifiques du Canada. Ils sont publiés dans la langue officielle choisie par l'auteur en fonction du public visé. En vue de déterminer si la demande est suffisamment importante pour produire ces rapports dans la deuxième langue officielle, le SCF invite les usagers à lui indiquer leur langue officielle préférée. Il faut envoyer les demandes de rapports techniques dans la deuxième langue officielle à l'adresse indiquée au verso de la page titre.

#### ABSTRACT

Little is known about the distribution, density and behaviour of moulting seaducks in the coastal waters of British Columbia. summarize in this report some of the information available on the distribution of moulting seaducks. Three species of seaducks moult in large numbers in the coastal waters of British Columbia: the Harlequin Duck (Histrionicus histrionicus), the Surf Scoter (Melanitta perspicillata) and the White-winged Scoter (Melanitta fusca). Harlequin Ducks moult in small groups of 20 to 200 birds along rocky shores and are well distributed along the coast. Large numbers of Harlequin Ducks moult in the northwest portion of the Strait of Georgia. Surf Scoters moult in larger groups (100-5,000 birds) in very localized areas. Among the major sites are: Boundary Bay, Hernando Island, Christie Islet in Howe Sound and the islands at the junction of Alice Arm and Hastings Arm in Observatory Inlet. Some of these sites seem to be traditional moulting areas. White-winged Scoters moult also in large groups. Known moulting sites include Comox, Boundary Bay, Bonilla Island and Rose Spit in the Queen Charlotte Islands. Data is lacking however to confirm whether these sites are used every year. Other species found in smaller numbers in the coastal waters in summer, include the Common Loon (Gavia immer), Western Grebe (Aechmophorus occidentalis) and the Greater Scaup (Aythya marila). facing moulting seaducks include oil spills, marine aquaculture, recreational boating, pollution, habitat destruction, and fishery activities. Among some of the research needed are: 1) the location of traditional moulting sites along the coast as only a

small portion of the coast of British Columbia has been surveyed to date; 2) the determination of whether these sites can be used to monitor and/or estimate population sizes; 3) the determination of the moulting chronology and of the composition of major moulting flocks, 4) the characterization of the moulting sites in terms of food, habitat and level of pollution; 5) the determination of relationships between breeding, moulting and wintering areas. Results of this research will benefit the many agencies involved in coastal development, impact assessment and policy development and will allow wildlife agencies to better monitor the health of seaduck populations and to adequately manage them.

#### RESUME

Il y a peu d'information sur la distribution, l'abondance et le comportement des canards de mer qui muent dans les eaux cotières de la Colombie Britanique. Je regroupe dans ce rapport une partie de l'information qui existe sur la distribution des canards de mer durand la période de la mue. Trois espèces de canards muent en grand nombre dans les eaux cotières de la Colombie Britanique. Ce sont le Canard Harlequin (Histrionicus histrionicus), la Macreuse a Front Blanc (Melanitta perspicillata) et la Macreuse a Ailes Blanches (Melanitta fusca). Le Canard Harlequin mue en petit groupes comprenant entre 20 et 200 individus le long de rivages rocheux et se retrouve tout le long de la côte. Ils sont particulièrement abondants dans la section Nord-ouest du détroit de Georgia. La Macreuse a Front Blanc mue

en gros groupes (100-5,000 oiseaux) a des endroits très localises. Parmi les sites les plus importants on retrouve: la baie Boundary, l'île Hernando, l'îlot Christie dans le détroit de Howe et les îles a la jonction des bras Alice et Hastings dans le passage Observatory. Certains de ces sites semblent être des endroits traditionels de mue. La Macreuse a Ailes Blanches, mue aussi en gros groupes. Les sites importants incluent Comox, la baie Boundary, l'Île Bonilla et extrémité nord-est de l'Île Graham dans les îles de la Reine Charlotte. La stabilité de ces concentrations n'a pas été établie cependant. Parmi les autres espèces qui fréquentent les eaux cotières en été, on retrouve le Huart a Collier (Gavia immer), le Grèbe de l'ouest (Aechmophorus occidentalis) et le Grand Morillon (Aythya marila). Plusieurs menaces pesent sur les canards de mer en mue: les déversements pétroliers, l'industrie d'aquaculture marine, les bateaux de plaisance, la pollution, la destruction de l'habitat, les activités de pêche. Les besoins en recherche incluent: localisation des sites de mue traditionels; jusqu'à présent une petite partie seulement des eaux cotières de la Colombie Britanique a été inventoriée; 2) déterminer si les sites de mue peuvent être utilisés pour suivre et/ou estimer les effectifs de canards de mer d'une année a l'autre; 3) déterminer la chronologie et la composition des principaux groupes en mue; 4) charactériser les sites de mue en terme de disponibilité de nourriture, d'habitat, et de degré de pollution; 5) déterminer les relations entre les sites de nidification, de mue, et d'hivernage. Les résultats de ces recherches seront utiles aux

divers organismes impliqués dans les dévelopements cotiers, dans les études d'impacts et dans le dévelopment de politiques. Ils devraient aussi permettre aux organismes fauniques d'effectuer un meilleur suivi de la santé des populations de canards de mer et de les aménager de facon adéquate.

#### **ACKNOWLEDGEMENTS**

I thank G.W. Kaiser, K. Vermeer, R. Butler, S. Wetmore, and N. Dawe for their comments on various drafts of this manuscript. Thanks also to P.M. Whitehead and L. Willis for their assistance in drafting the figures, and to S. Garnham for typing the manuscript. I am also grateful to G.W. Kaiser, S. Boyd and R. McKelvey for their field assistance, and to W.C. Campbell for providing access to the British Columbia Wildlife Record Scheme. This work was funded and supported by the Canadian Wildlife Service.

There are indications that large numbers of ducks moult in the coastal waters of British Columbia (Patch 1922, Guiguet 1953, Hay 1976, Vermeer and Levings 1977, Hatler et al. 1978, Martin 1978). However, the limited number of surveys during the July-August moulting season hinders our ability to assess the distribution, abundance and behaviour of these birds. In addition, our knowledge of seaduck moulting ecology is limited and also impairs our ability to successfully manage these species.

Seaducks are vulnerable to industrial activities during the moult. They are flightless, they concentrate, and they may have relatively high energy demands at this time (Weller 1957, Young 1977). In view of the increased maritime traffic along the west coast and of the probable renewal of offshore petroleum exploration it is urgent to document the abundance, distribution, and habitat requirements of moulting seaducks so that a baseline exists from which to define sensitive areas and assess potential impacts. This information will also help direct the development of the rapidly expanding aquaculture industry and minimize its impact on seaduck populations.

My objective in this report is to bring together the existing information on moulting seaducks in the coastal waters of British Columbia. This report includes information contained in an unpublished CWS Regional Report entitled "Moulting ducks in the coastal waters of British Columbia" (Savard 1981) as well as the results of new surveys conducted since its completion. It also summarizes the Royal British Columbia Museum Wildlife Records Scheme (BCWRS) for the months of July and August for Harlequin Ducks (Histrionicus histrionicus), Surf Scoters

(Melanitta perspicillata) and White-winged Scoters (M. deglandi) which moult in great numbers in B.C. coastal waters. The report identifies major threats to moulting ducks and areas for future research.

#### METHODS

#### 1. Historical records

The major sources of historical records were the sight records from the British Columbia Wildlife Record Scheme (BCWRS) and published literature. The sight cards report casual sightings by observers. Therefore the absence of sightings for an area may reflect more the absence of observers than the absence of birds. In spite of limitations, these data are useful in suggesting potential moulting sites. In some cases repeated sightings for an area may indicate traditional moulting areas. I have summarized only sightings during July and August because this is the period when seaducks are most likely to moult. mapped the sightings of the three major species of seaducks moulting along the coast of British Columbia: Harlequin Duck, White-winged Scoter and Surf Scoter. For each site where these species had been sighted I classified the foreshore as either cliffs, rocks, sandy and muddy based on nautical charts. each species, I then totalled the number of birds seen along each type of foreshore.

#### 2. Surveys

In the last decade, several surveys were done to locate concentrations of moulting seaducks:

- 1) In 1980, aerial surveys were carried out from a Beaver aircraft at a speed of 190 km/h and an altitude of 60 m. Observations were recorded on cassette tapes and transcribed at the end of each survey. The emphasis of the survey was on the location of moulting concentrations of ducks, although all birds seen were recorded. Aerial surveys were flown between July 28 and 31 in Chatham Sound (540N 1300W), Hecate Strait (530N 1310W) and Dixon Entrance (540N 1320W); and on August 7 in Boundary Bay (490N 1230W) near Vancouver. Several ground surveys were conducted in Boundary Bay throughout the summer and one in the Queen Charlotte Islands on July 31. Also, a detailed behavioural study of moulting Harlequin Ducks was done in 1984 near White Rock British Columbia.
- 2) On August 14, 1985, an aerial survey was flown over Boundary Bay, Indian Arm and Howe Sound using a Cessna 185 on floats at an altitude of 70 m. Only moulting concentrations were recorded during this survey.
- 3) On August 7, 8 and 25 1986, surveys were flown in Portland Inlet, Skidegate Inlet, Douglas Channel and over Hecate Strait from a Cessna 337. Again only concentrations of seaducks were recorded during the survey.

#### RESULTS

#### 1. Harlequin Duck

A) Data from the literature and the British Columbia Wildlife Record Scheme

Reports of Harlequin Ducks moulting in coastal waters of British Columbia are numerous (Guiguet 1953, Campbell 1964,

Campbell and Kennedy 1966, Kennedy and Foottit 1967, Foottit 1968, Foottit and Butler 1970, Hatler et al. 1978 and Martin 1978). Their moulting habits are similar to those of other populations of Harlequin Duck in Alaska and Iceland which also moult at sea (Gabrielson and Lincoln 1959, Bengston 1966).

The BCWRS indicate that moulting Harlequin Ducks are widely distributed along the B.C. coast including the Queen Charlotte Islands. Moulting flocks were reported from 84 locations along the coast during July and August (Appendix 1). At 61 (73%) of these locations, flocks contained less than 50 birds; only 12 (14%) sites had flocks of over 100 birds. No flocks over 500 birds have been reported. Sites with over 100 moulting birds included the Chain Islets off Victoria, Helliwell Park on Hornby Island, Cape Lazo near Comox, Mitlenatch Island, Oyster and Shelter Bays south of Campbell River. The site with the largest concentration of Harlequin Ducks was Mitlenatch Island with several records of over 300 birds (Appendix 1). Based on these records, the northwest section of Georgia Strait is an important moulting area for this species. More Harlequin Ducks were sighted along rocky shores (73%) than along sandy shores (28%) (Table 1). Harlequin Duck sightings were more restricted to rocky type shores (cliff and rocks) than those of Surf and Whitewinged scoters.

#### B) Data from surveys

Few Harlequin Ducks were seen during aerial surveys (Appendices 4,5,6). This probably reflects more, deficiencies in survey techniques than absence of Harlequins.

Table 1. Distribution of moulting seaducks according to foreshore type 1 as determined from nautical chart.

<sup>1 -</sup> No birds of any of the three species were sighted over muddy type
foreshores.

<sup>2 -</sup> Total number of individuals reported along a given type of foreshore.

The habit of Harlequin Ducks of resting among rocks close to shore impairs their detection from the air. This is compounded by their cryptic eclipse plumage which blends with adjacent rocks and floating kelp. During an aerial survey of Harlequin Ducks in Boundary Bay, only half of the 70 birds present were detected from the air.

During aerial surveys, especially those of 1980 we attempted to survey several species concurrently and concentrated on large flocks so that inconspicuous species such as Harlequin Ducks had less chance of being observed. Multiple species counts are less accurate than single species counts (Watson et al. 1969; Savard 1982). This was further compounded by the location of our flight lines 100 m from the tide line which impaired the detection of Harlequin Ducks from the air. Aerial surveys, limited to Harlequin Ducks and conducted at low altitudes along the tide line, might prove more effective in detecting that species.

#### C) Population study

A small population of Harlequin Duck was monitored from April to September 1980 near White Rock, B.C. Numbers fluctuated between 25 and 100 individuals (Fig. 1). The birds observed from May 14 to June 9 were probably non-breeders. The increase in numbers of Harlequin Duck drakes observed on June 16 probably represents the return of males from the breeding ground because the number of females did not change. Palmer (1976) and Bengston (1966) mentioned that males spend approximately four weeks on the breeding grounds before returning to sea. Counts indicate that the migration to breeding grounds took place between April 21 and

NUMBER OF HARLEQUIN DUCKS OBSERVED FIG. I ALONG 4 KM OF SHORELINE NORTH OF WHITE ROCK B.C.

May 14. More frequent counts would be required to pinpoint the event.

By June 28, 25% of the males had begun their postnuptial moult and were acquiring their eclipse plumage. On July 28, all males were in eclipse plumage and flightless. By mid-September the males were moulting to their nuptial plumage and were capable of flight.

Moulting Harlequin Ducks were relatively tame. They reacted to hikers moving along the shore by going into the water but returned to shore as soon as the disturbance passed. On one occasion the birds moved on shore when a seal approached them from the water. Moulting Harlequin Ducks reacted to boats by going into the water and swimming in a long line close to shore in very shallow water. Reaction to low flying aircraft was observed only once. Most birds resting on rocks went into the water, although a few remained on shore.

During all counts from April 20 to mid-September Harlequin Ducks remained within 50 m of shore. During their flightless period they spent most of their time resting on exposed rocks. This is reflected in the activity pattern recorded on July 28 from 0600 to 1400 hours (Figs. 2 and 3). All birds fed simultaneously in the early morning but after 0900 hours only small numbers of birds fed at any one time. Harlequin Ducks spent most of the daylight hours resting and preening on the shore (Fig. 3).

TIME

FIG 3 PERCENTAGE OF HARLEQUIN DUCKS RESTING ON LAND THROUGHOUT THE DAY (THE NUMBER OF BIRDS UNDER OBSERVATION RANGED FROM 30-80) (July 28)

#### 2. Surf Scoter

A) Data from the literature and the British Columbia Wildlife Record Scheme

Flocks of scoters were reported at 94 locations along the coast during July and August (Appendix 2). At 68 (72%) of these locations, flocks contained less than 100 individuals. Flocks of 100 to 500 individuals were reported at 20 sites (21%) and there were only 8 sites with flocks of over 500 birds: Hernando Reef, Tsawwassen, Christie Islet in Howe Sound, Douglas Channel, Grenville Channel, Rose Spit and Vargas Island.

More Surf Scoters were seen along rocky shores (56%) than along sandy shores (44%), and none were seen over muddy shores (Table 1).

#### B) Data from Surveys

Moulting flocks of Surf Scoters were very localized. The largest concentration was located around a group of islands at the junction of Alice Arm and Hastings Arm in Observatory Inlet. In 1986, I estimated 5,000 Surf Scoters in the sector (Appendix 6). In 1980, when only a small section of this sector was surveyed, 800 Surf Scoters were counted (Appendix 4). In 1976, at the same location, 3,000 Surf Scoters were counted by Chris Easthope (CWS Unpublished data). These observations show that some moulting sites are used for several years and may be traditional. This concentration is highlighted by the absence of Surf Scoters elsewhere in Observatory Inlet.

Another large moulting flock of Surfs Scoters occured in Boundary Bay near Vancouver where 2,000 to 4,000 scoters were counted in August 1980 (Appendix 4) and again 3,000 to 4,000 in

August 1985 (Appendix 5). Vermeer and Levings (1977) also reported large numbers of moulting Surf Scoters in Boundary Bay. In 1986 Surf Scoters were scattered in flocks of 50 to 300 individuals in the Bay with 2 major concentrations: one on the west side of the Bay and one on the east side (Appendix 5, Fig. 5.1).

A flock of 300 to 800 moulting Surf Scoters is located near Christie Islet in Howe Sound. It was first reported in 1977 (Appendix 2), and was seen again during the aerial survey of 1985 (Appendix 5). A concentration of moulting Surf Scoters was observed in Skidegate Inlet in 1980 (Appendix 4) and again in 1986 (Appendix 6). Another important concentration of Surf Scoter was located in 1986 in Douglas Channel near the northern tip of Hawkesbury Island (Appendix 6). Like previous ones, this appears to be a stable moulting location. Chris Easthope (CWS unpublished data) reported 2,000 birds there in 1976 and Hay (1976) also reported moulting flocks there.

These observations strongly suggest that some moulting sites are well defined areas that are used each year, thus the importance of identifying these areas and determining what attracts birds. Traditional use of these sites raises the possibility of using them to monitor population changes in the species.

Males tended to predominate summer concentrations of Surf Scoters, but the exact composition of moulting flocks has not been established yet. The sex ratio of a small group of Surf Scoters in Boundary Bay during the months of July and August averaged

Table 2. Sex ratio of Surf Scoters observed along a 4km long shoreline in Boundary Bay during the summer of 1981.

Date		Number of males	Number of females	Males/ female
July	2	77	32	2.41
	7	154	122	1.26
	9	180	76	2.37

	17	220	36	6.11
	21	387	88	4.40
	23	524	75	6.99
	29	276	45	6.13
August	4	238	118	2.02
	17	148	117	1.26
	21	201	89	2.26
Total		2,984	966	3.09

3.54±0.58 males per female and ranged between 1.26 and 6.99 (Table 2). Winter sex ratios for the same area averaged 1.84±0.29 males per female (n=6 counts). Palmer (1976) suggests that both pre-breeding and post-breeding birds are involved and Anweiler (1974) reports an influx of males in July and August. Along the Beaufort Sea coast of the Yukon Territory only post-breeding males have been reported (Gollop et al. 1974, Vermeer and Anweiler 1975, Johnson et al. 1975).

#### 3. White-winged Scoter

A) Data from the literature and the British Columbia Wildlife Record Scheme

Several authors (Patch 1922, Palmer 1976, Hay 1976, Vermeer and Levings 1977, Hatler et al. 1978) have reported White-winged Scoters moulting in British Columbia coastal waters. Palmer (1976) indicates that the centre of abundance of summering prebreeders is in waters of southeastern Alaska.

Flocks of White-winged Scoters were reported at 84 locations along the coast during July and August (Appendix 3). Flocks of less than 100 individuals were reported at 63 (75%) of these sites, of 100 to 500 birds at 15 sites (18%) and over 500 birds at 6 sites (7%). Sites with more than 500 birds were: Royston near Courtenay, Comox, the west side of Vargas Island; Barkley Sound; Cape Beal near Barkley Sound; and McIntyre Bay in the Queen Charlotte Islands. White-winged Scoters were sighted more often along sandy foreshores (58%), than along rocky shorelines (42%) and none were observed over muddy shores (Table 1).

#### B) Data from surveys

White-winged Scoters were the most abundant duck observed in aerial surveys conducted in the Queen Charlotte Islands in 1980 (Appendix 4). They were widely distributed throughout the censused area and a large concentration was located on July 29 near Bonilla Island. The birds were assembled in compact flocks of a few hundred, totalling at least 1,500 individuals. Similar concentrations have also been observed near Bonilla Island in fall and winter, indicating the importance of the area for White-winged Scoter (Savard 1979). In 1986, however, we could not locate this moulting concentration (Appendix 6). Whether birds had changed moulting site or whether we missed the flock, cannot be ascertained as we could not cover the whole area thoroughly. Further surveys are needed to establish the status of this moulting site.

No other large moulting concentrations of White-winged Scoters were located during the 1980 and 1986 aerial surveys (Appendices 4-6). Although high densities of White-winged Scoters were recorded in McIntyre Bay in 1980, the birds were scattered and did not form compact flocks like those near Bonilla Island. Patch (1922) mentions that the beach of McIntyre Bay was frequently "littered with feathers" of moulting scoters. In 1986 no large flocks were located in McIntyre Bay but again our coverage of the area was minimal.

Sex ratios taken during a ground survey along 10 km of shoreline near Sandspit in the Queen Charlotte Islands on July 31 yielded 368 males, 11 females and 21 unclassified individuals (Appendix 4). Most males were in nuptial plumage and probably had

not yet initiated their moult. The predominance of males in the counts indicates that they might be breeding birds that had returned from the nesting areas.

Aerial surveys may have missed some concentrations of White-winged Scoters. Shallow waters near Skedans Island, Bonilla Island and Rose Spit should be surveyed more intensively to monitor the build-up to the large numbers that winter there (Savard 1979).

#### 4. Other species

Regular surveys along a 4km length of shoreline near White Rock, British Columbia indicate that several species of aquatic birds spend the summer in coastal waters (Table 3). The three seaduck species discussed earlier were the most abundant summer residents, but other species were also seen in small numbers: Black Scoters (Melanitta nigra), Oldsquaws (Clangula hiemalis) and Scaups (Aythya sp.; probably marila).

#### A) Black Scoter

No mention of moulting Black Scoter was found in the literature for the coast of British Columbia. Palmer (1976) indicates only that the species moults in the Bering Sea, and Ross (1983) estimated that over 80,000 moulted in James Bay. A total of 26 Black Scoters, 17 males and 9 females, were observed in the Queen Charlotte Islands during July 1980 surveys (Appendix 4). Also, a few Black Scoters were seen in Boundary Bay during summer surveys (Table 2). This indicates that at least some Black Scoters moult in the coastal waters of British Columbia.

#### B) Oldsquaw

Only one Oldsquaw was observed in the aerial surveys of 1980, although Vermeer and Levings (1977) reported several hundred Oldsquaws summering in Boundary Bay. The absence of this species from our surveys may have been due to the location of our survey lines only a few hundred meters from shore, because Oldsquaws often frequent deeper waters than scoters (Vermeer and Levings 1977, Savard 1985). Summer surveys in Boundary Bay suggest that some birds spend the summer in the coastal waters of British Columbia (Table 2). Small numbers have been reported off Mitlenatch Island through July and August (R. Butler pers. comm.).

#### C) Greater Scaup

Scaups have been reported moulting in the coastal waters of British Columbia (Hay, 1976, Vermeer and Levings 1977). Palmer (1976) mentioned that most Greater Scaups moult on inland lakes but that a few moult at sea. Only a few flocks of scaups were recorded during the 1980 aerial surveys in the Queen Charlotte Islands (Appendix 4).

Some Common Loons (<u>Gavia immera</u>) and Western Grebes (<u>Aechmophorus occidentalis</u>) also spend the summer in B.C. coastal waters. Those are probably subadults who did not or do not migrate to their breeding area. Concentrations of post-breeding Red-necked Grebes (<u>Podiceps nigricollis</u>) have been reported in Boundary Bay in mid-August. Grebes and loons are thought to moult their wing feathers in the fall or winter (<u>Palmer 1962</u>),

but the exact chronology of the moult has not yet been documented for most species. Similarly, Ruddy Ducks are one of the rare waterfowl to moult their primaries twice a year, once in late summer on the breeding areas, and once during winter (Palmer 1976). Several hundred Ruddy Ducks winter in Boundary Bay near White Rock, B.C. (Savard 1985) but nothing is known of their ecology and moult chronology there.

#### 5. Threats to moulting seaducks

#### A) Oil Spills

Seaducks are extremely vulnerable when moulting because they become flightless and often form large and compact flocks. Scoters are especially vulnerable to oil spills (Clapp et al. 1982) and oil related deaths have often been documented (Aldrich 1938, Smail et al 1972, Vermeer and Vermeer 1974, Joensen and Hansen 1977, Vauk 1980, Clapp et al. 1982; Hooper et al. 1987).

#### B) Marine aquaculture

The development of the aquaculture industry along the coast could potentially threaten some moulting sites by either changing the habitat or by excluding birds from their traditional sites. Moulting seaducks in turn can create problems for some types of aquacultures, i.e. shellfish, by exploiting this new and accessible source of food.

#### C) Recreational boating

Boating is a potential threat but may not be permanent. Birds, unless continuously harassed, can usually adapt to some disturbance. However, any habitat change (i.e. construction of

marinas) or permanent disturbance could have a significant impact on moulting birds.

#### D) Pollution

Toxic pollution could affect the health of moulting seaducks. The largest concentration of moulting Surf Scoters found along the coast occurs at the mouth of Alice Arm, a polluted area. Similarly, moulting scoters in Howe Sound could be subjected to high levels of pollution. Toxic pollution can affect the birds either directly or by affecting the abundance and quality of food in the moulting areas. It may also affect the reproductive success of these birds (Hoffman and Albers 1984, Ohlendorf et al. 1986).

#### E) Habitat destruction

In view of the growing population and increasing natural resource needs, habitat destruction is a continuous threat. Industrial expansion, growth of the aquaculture industry, and growth of the recreation industry brings the need for more marinas and wharves, and logging, all of which could potentially destroy moulting sites directly or indirectly.

#### F) Fisheries

Drowning of wintering waterfowl in fishing nets can often be important in areas of high fishing intensity (Kirchhof 1982). Net fishing activities near important moulting sites could potentially cause high mortality.

## 6. Research Needs

Our level of knowledge on the distribution and ecology of moulting seaducks in the coastal waters in British Columbia is limited. Only a small fraction of the coast has been inventoried and little is known of the behaviour and ecology of moulting seaducks in British Columbia or in the world (Joensen 1973, Gollop et al. 1974). Considering the potential threats to these birds, some of the knowledge gaps should be filled. Presently, we do not have the information necessary to adequately manage these birds. Current impact assessments of coastal development (industrial, aquaculture) are impaired by this lack of information.

I list below a general list of research needs concerning moulting seaducks. The results of this research will benefit many agencies involved in coastal development, impact assessment and policy development. It will also allow wildlife agencies to better monitor the health of seaduck populations and to adequately manage them.

## A) Locate important moulting sites

Only a small portion of the coast has been surveyed to locate moulting concentrations of seaducks. Other areas that were surveyed once require more intensive surveys: Bonilla Island, Rose Spit and McIntyre Bay in the Queen Charlotte Islands.

B) Determine the stability of moulting sites.

There is some indication that major moulting sites of Surf Scoters and Harlequin Ducks are used consistently from year to year. However we have little data indicating whether the numbers of birds using these sites remain constant from year to year. Also, we do not know whether moulting sites of White-winged Scoters are used as consistently as those of Surf Scoters. Once the dynamic of moulting flocks is known it may be possible to monitor and even estimate size of populations by surveying important moulting areas.

C) Determine moulting chronology and the composition of moulting flocks

We have little data on moulting chronology and whether moulting sites are used at other times of the year. For example, do Surf Scoters have similar moult chronology in Boundary Bay and in Alice Arm? It is important to determine when birds become flightless and for how long, and whether all age and sex groups moult simultaneously. If not, then an oil spill could affect different portions of the populations depending on when it occurred.

Also, nothing is known of the relationships between moulting sites, breeding areas and wintering areas: Do birds of the same moulting flock originate from the same breeding area? Do they use the same wintering areas? What is the level of exchange between moulting sites? Those are not easy questions to answer, but are important because the impact of an oil spill or the destruction of a moulting site will have different implications depending on the answers.

D) Characterize moulting sites.

It is important to quantify the features of good moulting sites so that we can determine what attracts birds, what determines their numbers and to assess whether the sites are limiting along the coast. Such data would allow us to identify potential moulting areas and to rehabilitate disturbed habitats.

E) Determine pollution levels at major moulting sites.

What is the level of contamination, if any, of the food at various moulting sites along the coast? What is the level of contamination in scoters at these moulting sites? Growing primary feathers are known to concentrate heavy metals, thus may provide estimates of the level of toxics in a given area. Are scoters affected by pollution levels? Some toxic contamination affects reproductive output and could lead to population decline without any obvious dying off of birds (Hoffman and Albers 1984, Ohlendorf et al. 1986).

## CONCLUSION

A few studies have been done to describe the dynamics of moult in various species. These studies have documented a decrease in breast muscle during the moult paralleled with an increase in leg muscle (Hanson 1962, Ankney 1979, Young and Boag 1982). Originally this metabolising of muscle protein was taken as an indication of nutritional stress during the moult (Hanson 1962). However, recent studies suggest that this may not be so and that the fact of not using the breast muscle causes their atrophy (Aukney 1979, Young and Boag 1982). Also, some authors

explain the low body mass of ducks during wing moult as an adaptation to resume flight as early as possible (Douthwaite 1976, Pehrsson 1987). Recently Piersma (1988a,b) showed that moulting Great Crested Grebes (Podiceps cristatus) spent less time feeding and dived less often, and suggested that grebes are trying to minimize the risk of breaking the exposed and fragile flight feathers under water.

These studies indicate that more research is needed to fully understand the requirements of moulting birds and the stress associated with moult. Although some birds may not feed extensively during the moult, they may do so prior to or after, or may require specific feeding conditions during that time. Also, requirements may vary among species. It is therefore important to identify the needs of moulting birds to fully assess the importance and uniqueness of moulting sites.

At least six species of ducks moult in the coastal waters of British Columbia: White-winged Scoter, Surf Scoter, Black Scoter, Harlequin Duck, Oldsquaw and Greater Scaup. Among those species, the White-winged Scoter, Surf Scoter and Harlequin Duck are widely distributed and occasionally form large conspicuous, and apparently stable concentrations.

Moulting Harlequin Ducks are found mainly along rocky shores, whereas moulting Surf and White-winged scoters are found along both rocky and sandy foreshores, but with possibily Surf Scoters preferring rocky shores, and White-winged Scoters sandy shores.

Several important moulting sites have already been identified along the coast of British Columbia. Boundary Bay is important

for almost all species of seaducks during the moult. The junction of Hasting Arm and Alice Arm in Observatory Inlet is a very important site for Surf Scoters as more than 5,000 birds may moult there. The waters near Comox on Vancouver Island seem to sustain numerous White-winged Scoters along with those near Bonilla Island and McIntyre Bay in the Queen Charlotte Islands. The limited number of aerial surveys showed the concentrated nature of moulting birds and the discrete nature of moulting sites.

More surveys are needed to define adequately the distribution of moulting seaducks in British Columbia coastal waters. The moult migration of those species is poorly understood and their behaviour and habitat selection during moult has not been studied in British Columbia although some studies have been done elsewhere (Joensen 1973, Gollop et al. 1974). The large numbers of seaducks concentrating along the west coast make the area critical for the survival of those populations. The birds cannot be protected from the impact of human activities unless their requirements are better understood.

group 101 - 500 birds

group > 500 birds

The enclosed number refers to Appendix 2.3 where the actual sight records are given. Figures 2.1 and 2.2 present only the largest sighting for each location.

Appendix 2.1 July and August BCWRS records of Surf Scoters in the Queen Charlotte Islands.

Appendix 2.2 July and August BCWRS records of Surf Scoters along Vancouver Island and the adjacent mainland coast.

APPENDIX 2.3. Detailed BCWRS records for Surf Scoters.

NO. LOCATION (MAP GRID)	DATE	BIRDS SEEN	COMMENTS
1 BROWNING INLET, GRANT BAY (1021/8)	JUL ?/68	15	WINTER HARBOUR
2 SOUTH BAY, TRIANGLE ISLAND (1021/14)	JUL 11/78	11	
3 OFF SOUTH CAPE SAINT JAMES (1020/14)	AUG 10/81	. 10

Appendix 3. British Columbia Wildlife Record Scheme (BCWRS) for White-winged Scoters for the months of July and August.

- 3.1 July and August BCWRS records of White-winged Scoters in the Queen Charlotte Islands.
- 3.2 July and August BCWRS records of White-winged Scoters along Vancouver Island and the adjacent mainland coast.
- 3.3 Detailed BCWRS records for White-winged Scoters.

Legend for figures

group < 50 birds

group 51 - 100 birds

group 101 - 500 birds

group > 500 birds

The enclosed number refers to Appendix 3.3 where the actual sight records are given. Figures 3.1 and 3.2 present only the largest sighting for each location.

Appendix 3.1 July and August BCWRS records of White-winged Scoters in the Queen Charlotte Islands.

Appendix 3.2 July and August BCWRS records of White-winged Scoters along Vancouver Island and the adjacent mainland coast.

APPENDIX 3.3. Detailed BCWRS records for White-winged Scoters.

Appendix 5. Results of Aerial surveys conducted on August 14, 1985 in Boundary Bay, Indian Arm and Howe Sound.

5.1 Location of survey lines

Appendix 5. Results of an aerial survey conducted on August 14, 1985 in Boundary Bay, Indian Arm and Howe Sound.

The purpose of the survey was to assess the number of moulting scoters in Boundary Bay and to locate moulting concentrations of ducks in Indian Arm and Howe Sound. The survey was flown at 200 feet in a Cessna 185 on floats. The route followed in Indian Arm and Howe Sound is mapped in Appendix 5.1. The survey started at 1000h. The tide was low. The observers were Rick McKelvey and Jean-Pierre L. Savard.

#### Fraser Foreshore

We flew over the tide line which was far from shore because of the low tide. No birds were observed over Sturgeon Banks. Two flocks of Surf Scoters were located on Roberts Bank. One estimated at 200 birds just west of the Coal Terminal (Appendix 5.2, No. 1) and one between the coal jetty and the ferry jetty estimated at 100 birds (Appendix 5.1, No. 2).

### Boundary Bay

We flew first at 700 feet to locate concentrations of scoters and then carried out a few transects at 200 feet. Scoters were scattered in small groups ranging from 40 to 300 individuals. Both Surf and White-winged scoters were present. Surf Scoters seemed to outnumber White-winged Scoters. Scoters were concentrated in two areas of the Bay, first approximately in front of the Boundary Bay Airport and

Appendix 5.1 Boundary Bay Indian Arm and Howe Sound Molting Bird Survey - August 14 1986

Appendix 5.1 Location of survey lines in Boundary Bay, Indian Arm and Howe Sound on August 14, 1986.

second, just offshore of Kwomais Point (Appendix 5.1). I estimated between 3,000 and 4,000 scoters in the Bay. Scoters were difficult to locate and count because of the survey conditions. During a survey flown over the Bay on September 19, 1985, scoters were concentrated in the same two sections of the Bay as on August 14. A few hundred seals were loafing along the tide channels. Fifty Harlequin Ducks were counted near Kwomais Point. They were difficult to see from the air. Red-necked Grebes were observed (~100) over the eelgrass bed off Crescent Beach (Appendix 5.1).

## Indian Arm

No concentration of waterfowl was located in Indian Arm. The area was characterized by the absence of birds. The shoreline appears to support few mussel beds. Only a few patches of mussels were seen from the air. We only saw a few Common Mergansers (Mergus merganser) and Common Loons.

#### Howe Sound

No concentration of waterfowl was seen between the Lions Gate Bridge and Horseshoe Bay. In fact only three concentrations of scoters were located along the route flown in Howe Sound. The first group of scoters was seen near Christie Islet (Appendix 5.2) and comprised approximately 300 scoters, mostly Surf Scoters. The second group was near the Defence Islands (Appendix 5) and was estimated at 400 individuals, mostly Surf Scoters. Finally, the third concentration was seen between Hutt Island and Bowen Island

(Appendix 5.1) and comprised 75 Surf Scoters mostly females and still capable of flight.

- Appendix 6. Results of aerial surveys conducted on August 7, 8 and 25, 1986 around Hecate Strait.
- 6.1 Location of survey lines in Observatory Inlet, Hecate Strait and Douglas Channel.
- 6.2 Skidegate Inlet (Insert A)
- 6.3 Alice Arm (Insert B)

Appendix 6. Results of aerial surveys conducted on August 7, 8 and 25, 1986 around Hecate Strait.

The purpose of these surveys was to locate concentrations of moulting seaducks. The surveys were flown in a Cessna 337 at altitudes ranging between 50 and 100 m. On August 7 and 8, three observers looked for concentrations of birds and on August 25, only two observers.

#### Kitimat Arm and Moore Islands

Only one major concentration was located during this survey (August 7, Appendix 6.1). It was located at the north end of Devastation Channel near Kersey Point (Appendix 6.1, No. 8-9). A smaller flock was seen in Kitkiatka Inlet (No. 10 ~ 200 Surf Scoters) and a small group of 75 Surf Scoters was seen at the south end of Fin Island (Appendix 6.1, No. 11). No other concentrations of birds were seen along the surveyed route.

# Observatory Inlet, Skidegate Inlet, Masset Inlet, Naden Harbour and Hecate Strait

The survey was flown on August 8 (Appendix 6.1) and two major concentrations of Surf Scoters were located. The largest concentration totalled close to 5,000 Surf Scoters and was located around the islands at the intersection of Alice and Hastings arms (Appendix 6.1, No. 7). Group size ranged from 50 to over 3,000 scoters scattered among the islands. The location of the major flocks is shown in Appendix 6.2. A small flock of 200 Surf Scoters was seen in

Appendix 6.1 Location of survey lines in Observatory Inlet, Hecate Strait and Douglas Channel.

Appendix 6.2 Insert area B: location of survey line near Alice Arm.

Nasaga Gulf near the mouth of Portland Inlet (Appendix 6.1, No. 6). The only other large group of moulting scoters was found in Skidegate Inlet where 1,500 Surf Scoters were counted (Appendices 6.1, 6.3). No large flocks of moulting seaducks were encountered along the rest of the survey route. A few groups of mergansers were seen in Masset Inlet, but those may have been old broods.

# Moresby Island and Bonilla Island

No concentrations were located on August 25 along this line (Appendix 6.1). However, because of the size of this area and the small area covered by our survey line, it is possible that concentrations were overlooked.

Appendix 6.3 Insert area A: location of survey lines in Skidegate Inlet.
