TECHNICAL REPORT SERIES CANADIAN WILDLIFE SERVICE

This series of reports, established in 1986, contains technical and scientific information from projects of the Canadian Wildlife Service. The reports are intended to make available material that either is of interest to a limited audience or is too extensive to be accommodated in scientific journals or in existing CWS series.

Demand for these Technical Reports is usually confined to specialists in the fields concerned. Consequently, they are produced regionally and in small quantities; they can be obtained only from the address given on the back of the title page. However, they are numbered nationally. The recommended citation appears on the title page.

Technical Reports are available in CWS libraries and are listed in the catalogue of the National Library of Canada in scientific libraries across Canada. They are printed in the official language chosen by the author to meet the language preference of the likely audience, with a résumé in the second official language. **To determine whether there is significant demand for making the reports available in the second official language, CWS invites users to specify their official language preference. Requests for Technical Reports in the second official language should be sent to the address on the back of the title page.**

SÉRIE DE RAPPORTS TECHNIQUES DU SERVICE CANADIEN DE LA FAUNE

Cette série de rapports donnant des informations scientifiques et techniques sur les projets du Service canadien de la faune (SCF) a démarré en 1986. L'objet de ces rapports est de promouvoir la diffusion d'études s'adressant à un public restreint ou trop volumineuses pour paraître dans une revue scientifique ou l'une des séries du SCF.

Ordinairement, seuls les spécialistes des sujets traités demandent ces rapports techniques. Ces documents ne sont donc produits qu'à l'échelon régional et en quantités limitées; ils ne peuvent être obtenus qu'à l'adresse figurant au dos de la page titre. Cependant, leur numérotage est effectué à l'échelle nationale. La citation recommandée apparaît à la page titre.

Ces rapports se trouvent dans les bibliothèques du SCF et figurent aussi dans la liste de la Bibliothèque nationale du Canada utilisée dans les principales bibliothèques scientifiques du Canada. Ils sont publiés dans la langue officielle choisie par l'auteur en fonction du public visé, avec un résumé dans la deuxième langue officielle. **En vue de déterminer si la demande est suffisamment importante pour produire ces rapports dans la deuxième langue officielle, le SCF invite les usagers à lui indiquer leur langue officielle préférée. Il faut envoyer les demandes de rapports techniques dans la deuxième langue officielle à l'adresse indiquée au verso de la page titre.**

Abstract

The need for a Piping Plover banding study became evident in the early 1990s, when several years of good productivity (greater than 1.5 chicks fledged per pair) suggested that an increase in regional population numbers could be expected. However, the regional population declined by approximately 17% between the two International Censuses, conducted in 1991 and 1996. The eastern Canada Piping Plover population was the only population that did not increase over that five-year period.

In 1998, a research program was initiated to answer key questions related to survival, dispersal, and other population dynamics of eastern Canadian Piping Plovers. This report summarizes the banding protocol and effort and study areas of this research program.

A protocol was developed to implement a consistent region-wide study aimed at minimizing disturbance while maximizing the amount of information that could be obtained. Strict timelines for capture and handling, and specifications for conditions where banding could occur, were key components of the protocol.

Adult Piping Plovers were captured during the majority of the study using a modified Weller nest trap; however a box trap was used initially. Chicks were captured by hand. Two bands were placed on each bird, one on each lower leg (tarsometatarsus). A standard 1A stainless steel or 1B incoloy USGS band was placed on one leg, while a province-specific colour band was placed on the opposite leg. The only exception was 1998, when stainless steel USGS bands were placed on the upper leg. The USGS band was placed on the right leg of adults and on the left leg of chicks, to allow recognition of age classes from a distance for returning birds.

Over the course of the study, 888 Piping Plovers were banded in eastern Canada. The

detailed results of this research will be published elsewhere.¹

¹ At the time of writing this report, the detailed results of this research have not yet been published. The report is currently being prepared for publication and will be submitted to the Canadian Journal of Zoology. It is anticipated that the journal will publish the report in 2001.

Résumé

La nécessité d'une étude de baguage sur le Pluvier siffleur est devenue évidente au début des années 1990, lorsque plusieurs années de bonne productivité (plus de 1,5 oisillon prenant son envol par couple reproducteur) ont laissé entrevoir un accroissement de la population de Pluviers siffleurs dans la région. Cette population a toutefois baissé d'environ 17 p. 100 entre les deux recensements internationaux effectués en 1991 et en 1996. La population de Pluviers siffleurs de l'est du Canada est la seule à ne pas avoir augmenté au cours de ces cinq années.

En 1998, on a mis sur pied un programme de recherche pour tenter de répondre à des questions essentielles touchant à la survie, à la dispersion et à d'autres paramètres relatifs à la population de Pluviers siffleurs de l'est du Canada. Le présent rapport résume le protocole de baguage, l'effort de baguage déployé et présente les zones d'études de ce programme de recherche.

On a mis au point un protocole pour la mise en œuvre d'une étude cohérente à l'échelle de la région, protocole visant à obtenir le maximum de renseignements, tout en perturbant le moins possible la population. Un échéancier très précis de capture et de manipulation ainsi que des lignes directrices strictes sur les conditions de baguage ont été des éléments essentiels de ce protocole.

On a capturé les Pluviers siffleurs adultes pendant la majeure partie de l'étude à l'aide d'un piège de type Weller modifié; au départ, une boîte de capture au nid a toutefois été utilisée. Les oisillons ont été attrapés à la main. Deux bagues ont été posées sur chaque individu, à savoir une sur la partie inférieure de chaque patte (tarso-métatars). Une bague standard 1A en acier inoxydable ou une bague USGS 1B en incoloy a été posée sur une patte, tandis qu'une bague dont la couleur variait selon la province a été placée sur l'autre patte. La

seule exception fut l'année 1998, pendant laquelle on a posé une bague USGS en acier inoxydable sur la partie supérieure de la patte, à savoir sur la patte droite chez les adultes et sur la patte gauche chez les oisillons, afin de pouvoir distinguer d'une certaine distance les classes d'âge lors du retour des oiseaux dans la région.

Tout au long de l'étude, on a bagué 888 Pluviers siffleurs dans l'est du Canada. Les résultats détaillés de cette étude seront publiés ailleurs.

Acknowledgements

We are grateful to all individuals who reviewed and provided input for the development of the banding protocol; most notably the following individuals: Dr. Francesca Cuthbert (University of Minnesota), Dr. Stephen Flemming (Parks Canada), Paul Goossen (Canadian Wildlife Service, Prairie and Northern Region), Dr. Cheri Gratto-Trevor (Canadian Wildlife Service, Prairie and Northern Region), Anne Hecht (USFWS Fish and Wildlife Service), and Dr. Scott Melvin (Massachusetts Division of Fisheries and Wildlife).

Thanks are extended to the banders that helped to implement the study: Andrew Boyne, Dr. Stephen Flemming, Pierre Laporte, Julie McKnight and Peter Thomas. The eastern Canada Piping Plover recovery team and working group supported the research program from the onset and provided the necessary support and guidance to ensure its success. Pedro Blanco kindly provided guidance in development and use of the modified Weller trap.

Ian Amirault-Langlais and Dr. John Chardine provided technical assistance for the completion of this report. The report benefited from an editorial review completed by Dr. Richard Elliot.

The eastern Canada Piping Plover banding research program was made possible due to the contributions of many agencies, organizations, and the efforts of countless dedicated individuals. To these individuals we express our sincere gratitude.

Funding for the program and the preparation of this report was provided by the Canadian Wildlife Service, Atlantic and Québec Regions.

Introduction

A tremendous amount of research, monitoring and conservation effort has been focused on the eastern Canada population of Piping Plovers (*Charadrius melanotos melanotos*) since the species was identified as *Endangered* in Canada in 1985 (Haig 1985). These efforts have contributed to the large body of data regarding the status of the regional population. International population censuses conducted in 1991, 1996 and 2001 have produced reliable indications of population trends (Flemming 1994, Goossen and Amirault 2004, Amirault 2005).

The first comprehensive survey of all known and potential eastern Canada Piping Plover breeding habitats occurred in 1991, during the first International Census. At that time, the population was estimated at 509 adults (Flemming 1994). The second International Census conducted in 1996 showed a population decline of approximately 17% to 422 adults (Goossen and Amirault 2004). This was the only portion of the Atlantic Coast (*melanotos* subspecies) population which declined during this period. Although the last International Census conducted in 2001 indicated an improvement from 1996, the population level remained lower than in 1991 at 481 adults. This population decrease was unexpected, since eastern Canada populations had consistently achieved the target rate of 1.5 chicks fledged per pair, among the highest productivity rates of any Piping Plover population in North America (Haig and Elliott-Smith 2004). Estimates of productivity reported in eastern Canada from 1991-2006 are presented in Appendix 1. These estimates comprise a consolidation of information from conservation groups and agencies across the region. Numbers reported represent the total number of chicks reaching the age of 20 days (defined as a fledged chick for reporting purposes) per pair followed from nest initiation to hatching or nest loss. Separating re-nests from initial nesting attempts is often difficult if birds are unbanded. Re-nesting is therefore reported as follows: unsuccessful nesting attempts are reported as one monitored pair with no chicks hatched or fledged and any subsequent successful or unsuccessful attempts are reported as another monitored pair unless that pair was confidently identified as the same pair. For example, when both birds in the pair are banded and their identity confirmed, or when a new nest is discovered near a nest that was lost during the egg laying or incubation stage.

Coincident with this regular monitoring, considerable time, effort and funding were expended in Piping Plover conservation efforts. As the anticipated population recovery in response to conservation attention did not materialize, a banding program was planned to collect information needed to determine why the status of the Eastern Canada population was not improving.

Rationale for a banding and research program

A banding project was initiated to ensure that the Piping Plover recovery program was based on sound biological information and appropriate estimates of population parameters. Data were collected as the basis for a research program involving population viability

Banding protocol

A review of pertinent literature (Wilcox 1959, MacIvor et al. 1990, Calvo and Furness 1992, Reed and Oring 1993, Gratto-Trevor 1994, Amat 1999, Lingle et al. 1999) and discussions among experienced banders across North America were conducted to develop the banding protocol. The draft protocol was reviewed by the eastern Canada Piping Plover Recovery Team. The Piping Plover banding protocol and research program were developed with special attention to minimizing disturbance, and reducing the risk of injury, mortality and lowered productivity, based on other successful research programs (Wemmer and Cuthbert 1998). A separate protocol was established to identify the appropriate response to mortality or injury that resulted from capturing, handling or banding birds (Appendix 2).

The banding protocol was adapted during the study to take advantage of new information, and regular evaluations were undertaken to determine what impact the banding program may have had on Piping Plovers. Procedures described below identify any changes from the original methodology, as well as a rationale for those modifications. The study spanned a total of nine years: an initial protocol was tested in 1998; intensive banding and recaptures occurred from 1999 to 2003; and opportunistic recapture of banded individuals occurred between 2004 and 2006.

Methods

Efforts to minimize disturbance

Trapping of adults on their first nesting attempts was favoured, in order to minimize disturbance and stress, and avoid potential effects on Piping Plover productivity. Only one adult per pair was normally trapped. However, capture on renesting attempts or of both adults was occasionally undertaken with appropriate caution, if the bander judged that trapping would have little risk of impacting nesting success or posing undue stress.

Captures were timed to increase the chance of success and minimize disturbance. Capture of adults generally occurred 7-25 days after initiation of incubation to minimize risk of nest abandonment. Occasional capture attempts less than seven days into incubation were undertaken at the discretion of the bander. Most young were banded at age 7-14 days, as banding of older, more mobile juveniles was thought to result in greater disturbance. All captures occurred when weather conditions were good, defined as light to moderate winds, no precipitation and air temperatures close to 15°-25°C. Banders considered weather conditions, likelihood of success, and effect of disturbance when evaluating whether a subsequent capture attempt on the same day was appropriate, and no more than three attempts were made to trap any individual plover. Only experienced banders that showed proficiency in banding Piping Plovers were involved in capturing or banding birds.

A maximum of 15 minutes was allowed for the adult to enter the trap, in order to minimize the overall level of disturbance. The trap was removed if the adult had not returned to the nest in that period. The adult was removed from the trap by hand immediately following capture. Birds were released as soon as possible, with a maximum handling time of 10

minutes per adult for banding, measurement, and photography. No trapping was conducted on nesting beaches where there was a presence or evidence of large numbers of predators, or where trapping was expected to increase the likelihood of predation. Trap set-up and handling techniques were practiced away from nests in advance, in order to increase efficiency and reduce the time and disturbance involved.

Trap designs

A modified Weller trap (Weller 1957) set over the nest was used during most of the banding program (late June 2000 to 2006). Traps were constructed of 1.25 inch (3.18 mm) plastic-covered wire mesh, similar to materials used to construct lobster traps. The wire was bent into a round shape and fine netting, normally used in the aquaculture industry for spat collection (Netron extruded polyethylene) covered the top portion of the trap. A second layer of plastic-covered wire mesh was placed on the outside of the trap, as some birds occasionally escaped through the single layer of mesh. Plastic ties secured the wire mesh. A door suspended by a fine monofilament fishing line allowed the adult to reach the nest. The line looped through the top mesh of the cage, down through the bottom mesh, and over the top of the eggs to end in a loop attached to a peg near the eggs. When the adult returned to incubate the eggs, it pushed the loop off the peg, causing the door to drop under its own weight, and capturing the bird inside the trap. The trap was placed over the nest so that the door was opposite of the direction of the prevailing wind, allowing birds to approach the nest and enter the trap facing into the wind.

Captures prior to late June 2000 were made with a box trap set over the nest. A pin with a string attached held the door in place. When an adult had entered the trap and settled on the eggs, the string was pulled by an observer to dislodge the pin, causing the door to fall and trap the adult inside. Although this technique was used successfully to capture Piping Plovers, it was less efficient than the modified Weller Trap. The square design caused difficulties for some birds to locate the door, and the bulky frame may have caused some birds to be suspicious and prevent them from entering the trap.

At those nests where exclosures were used to keep predators away, the trap was usually placed inside the enclosure. In these cases, the enclosure was partially lifted to allow the trap to be placed on the nest and secured immediately after capture was completed. Complete removal of an exclosure usually confused the birds, as they appeared to use that structure to locate their nests and often returned to the displaced exclosure rather than the actual nest site. Some exclosures were built to facilitate banding, with a door in the wire mesh held in place with plastic ties. The ties were removed to allow a researcher to enter the enclosure to place the trap over the nest, and new ties were placed to secure the door once the activity was complete. Attempts were made to remove evidence of human activity near the nests to minimize the attraction of predators, especially when exclosures were not used.

All banding took place and measurements were taken a considerable distance from the nest to minimize researcher activity in the vicinity of the nest site. This was done to decrease the risk of predation for nests without exclosures, minimize the risk of abandonment due to human presence at the nest and permitted the other adult to access the nest in order to

resume incubation. A minimum number of researchers (normally only two persons) was used to safely and quickly place the trap on the nest, retrieve the captured bird and erase footprints or other evidence of human activity at the nest site.

Most chicks were captured by hand, occasionally facilitated by using small insect nets gently placed over the young bird. Most captures were conducted by a group of persons equal to the number of chicks present. The team approached from the top of a dune, with each person selecting one chick to follow. They walked towards each chick in the direction of the water's edge, following the chick until it crouched on the sand and could be easily picked up. Only one attempt was made to capture each brood. The entire brood was captured together, and after banding the chicks were released simultaneously to maintain the family unit. This was done because if only a portion of the brood was captured, the adults would lead the remaining chicks away, making it difficult to reunite the banded chicks with the rest of the family group.

Timing of adult captures varied between study areas, and depended on the frequency of renesting. Most took place from late May to early July. Most juvenile plovers were banded from late June to early August, again depending on the timing of renesting.

Information collected

The band number, band colour, age, sex, date and location were recorded for each adult bird banded. Adults were sexed on the basis of their behaviour, bill colouration and plumage characteristics (Cairns 1982). The band number, band colour, date and location were recorded for chicks. The age and sex of all chicks were classified as "Local," "Unknown" for banding report purposes.

Several measurements were recorded for adult birds. Mass (± 0.1 g) was measured with a pesola-type scale, maximum wing chord and tail length (± 0.1 mm) were measured with a wing rule, and culmen length (± 0.1 mm) was measured using calipers. The maximum and minimum widths of the dark throat stripe were occasionally measured to assist in determining the sex of adults, and notes were recorded on plumage characteristics. The degree of primary feather wear was noted to evaluate the potential for distinguishing between second-year and older adult birds.

Some banded adult plovers were photographed to assess the potential for using plumage and bill characteristics to identify individual birds in subsequent years. A series of four photographs was taken: a side-view of the bill to assess the use of the relative amount of bill colour (red-orange and black) to identify male and female birds, a side view of the head and bill for later measurement, a side view of the entire bird, and a frontal image of the bird to document the characteristics of the neck band.

In order to allow sufficient time to band several chicks within ten minutes, only the mass (± 0.1 g), measured with a pesola-type scale, and maximum wing chord (± 0.1 mm), measured with a wing rule, were recorded for chicks.

After banding and release, or removal of the trap after unsuccessful attempts, birds were observed from a distance of at least 100 m, until it was considered that they had resumed normal behaviour. After broods were released, chicks were observed from a similar distance to confirm that they were reunited with their parents. The amount of time required for adults to return to the nest was recorded. Whenever possible, banded birds were monitored every 1-3 days to detect problems resulting from banding.

The impact of banding was evaluated through discussions with Piping Plover monitoring groups at the end of the breeding season, to determine the fate of each nest and to determine whether banded chicks were known or thought to have fledged. Hatching and fledging success of family groups in which some individuals were banded was determined, to evaluate whether banding affected their productivity.

Banding Scheme

The only USGS metal bands available in sizes approved for Piping Plovers (1A or 1B) have inscriptions on the inside, although it is recommended that bands without such engravings be used to minimize the risk of injury (Lingle et al. 1999). We therefore used these bands of the recommended size, while monitoring for problems associated with inside engravings, so that other approaches could be used if concerns arose.

With the exception of the initial protocol development year (1998), both adult and juvenile birds were marked with two bands, one on the lower part of each leg (the tarsometatarsus). USGS bands were placed on the upper leg in 1998. One leg carried a 1A or 1B USGS metal band, while the other carried a size 1A plastic or anodized aluminium colour-band identifying the province of banding. This banding scheme was adopted across eastern Canada, with the exception of the type of USGS bands used. In Atlantic Canada, 1A stainless steel USGS bands were used in 1998 and 1B incoloy USGS bands used thereafter. On the Magdalen Islands (Québec), 1A stainless steel USGS bands were used throughout the study. All bands were inspected prior to use, in order to discard imperfect bands and polish down any sharp edges.

To indicate the province of banding, several different types of colour bands were used for colour bands during this study. As Piping Plover populations overlap during the winter, colour combinations used in other jurisdictions were avoided to prevent identification problems. The colour band regime was changed between years in order to avoid duplication, and in response to fading and loss of plastic bands. Single colour or bicouleur plastic bands were used initially, but proved not to be UV-stable. They were replaced with anodized colour aluminium bands carrying alpha-codes (letters), because no UV-stable colour combinations were available that had not been previously used in other Piping Plover studies. Anodized aluminium bands were a suitable alternative to plastic bands due to the range of colours available. The aluminium bands had unique two-letter alpha codes to aid in identifying individual birds from a distance, with the letters either side-by-side (horizontal) on a shorter colour band (height = 6.5 mm) or one above the other (vertical) on a taller colour band (height = 9.1 mm) (Amirault et al. 2006). Taller colour bands were eventually used to permit reading both letters simultaneously, which facilitated identification of birds from a distance. Table 1 summarizes the colour band colours and

types used over the course of the study. Figure 1 illustrates the colour bands used and provides examples of typical band wear.

Table 1. Types of colour bands used on Piping Plovers in eastern Canada, 1998-2003.

	1998		1999-2000		2001		2002-2003	
	Colour scheme	Band type	Colour scheme	Band type	Colour scheme	Band type	Colour scheme	Band type
NB	dark green	plastic single-colour	white / light blue	plastic bicolour	dark blue / green	metal bicolour (horizontal alpha codes)	dark blue / green	tall metal bicolour (vertical alpha codes)
NL	light green	plastic single-colour	pink / dark blue	plastic bicolour	red / dark blue	metal bicolour (horizontal alpha codes)	red / dark blue	tall metal bicolour (vertical alpha codes)
NS	-	-	yellow / light green	plastic bicolour	red / black	metal bicolour (horizontal alpha codes)	red / black	tall metal bicolour (vertical alpha codes)
PEI	red	plastic single-colour	red / dark green	plastic bicolour	red / dark green	metal bicolour (horizontal alpha codes)	red / dark green	tall metal bicolour (vertical alpha codes)
QC	grey	plastic single-colour	grey	plastic single-colour	blue / purple	metal bicolour (horizontal alpha codes)	blue / purple	tall metal bicolour (vertical alpha codes)

Note - No birds were banded in Nova Scotia in 1998.

Adults and juvenile plovers were distinguished by the location of the bands. Adults had the colour band placed on the left leg and USGS band on the right, whereas juveniles had the colour band on the right leg and USGS band on the left.

No numerical banding targets were established. Instead, as many adult and juvenile plovers as possible were banded, keeping in mind the need to minimize negative impacts on nesting birds, challenges in gaining access to many sites, and the availability of staff time and resources. In later years of the study, additional emphasis was placed on recapturing banded individuals to confirm the identity of banded birds, and replace worn or remove constrictive bands. This additional effort to identify individuals enabled stronger confidence intervals to be established when conducting population modeling exercises.

Study areas

The study focused on Piping Plover beach habitats that were regularly monitored by conservation groups in New Brunswick, insular Newfoundland, Nova Scotia, Prince Edward Island and Québec. Monitors familiar with the sites were often able to provide advice on selecting the best locations for banding. Over the course of the study, banding occurred at 80 sites in eastern Canada (Figure 2).

The Piping Plover banding protocol was field-tested in 1998 at a few sites in New Brunswick, Newfoundland, Prince Edward Island and Québec. The program was fully implemented between 1999 and 2003, with effort expended in all five jurisdictions, except that no banding occurred in Newfoundland in 1999. In 2004, 2005 and 2006, emphasis was placed on re-sighting bands, and opportunistic capturing birds to remove metal colour bands (Amirault et al. 2006).

Banding effort

A total of 888 birds was banded, including 329 adults and 559 chicks. The largest number of birds was banded at 19 sites in the province of New Brunswick (255, including 89 adults and 166 juveniles); 209 were banded at 20 sites in Nova Scotia (including 75 adults and 134 juveniles); 180 were banded at 20 sites in Prince Edward Island (including 69 adults and 111 juveniles); 157 were banded at 9 sites in Québec (including 62 adults and 95 juveniles); and 87 were banded at 12 sites in Newfoundland (including 34 adults and 53 juveniles). The numbers of adult and juvenile birds banded at each site are summarized in Table 2.

Three sites figure prominently in the total number of birds banded: Plage de l'Hôpital (QC), Bouctouche Bar (NB) and Cavendish Sandspit (PE). At these sites, 18.4% of the total regional number of birds was banded. The largest number of birds was banded at Plage de l'Hôpital (65 birds, or 7.3% of total); 52 were banded at Cavendish Sandspit (5.8% of total); and 46 were banded at Bouctouche Bar (5.2% of total). Seven sites were notable for banding of significant numbers of juvenile birds: Plage de l'Hôpital (QC) (42), Bouctouche Bar (NB) (34), Cavendish Sandspit (PEI) (33), Dune de Neguac (NB)(29), Crow Neck (NS)(27), St. Catherines River (NS)(27) and Covehead Harbour (PE)(22).

Although significant numbers of Piping Plovers were banded within protected areas (national parks, national wildlife areas, provincial parks, ecological reserves), the majority of birds (71%) were banded outside these areas. A total of 210 Piping Plovers were banded within National Parks of Canada: 115 in Prince Edward Island NP (PE), 59 in Kouchibouguac NP (NB) and 36 in Kejimkujik NP Seaside Adjunct (NS); 33 were banded in Nova Scotia Provincial Parks: 12 at Summerville, nine at Sand Hills, eight at Pomquet, and four at Sandy Bay (Thomas Raddall Provincial Park); four were banded in the J.T. Cheeseman Provincial Park in Newfoundland and Labrador and one was banded at the

Cabot Provincial Park in Prince Edward Island; eight were banded in National Wildlife Areas: six at Portage Island (NB)(6) and two at Cape Jourimain (NB); and five were banded at Big Barasway Ecological Reserve (NL). A summary of initial activities is included in Appendix 3.

Seven banders participated in the study, including: Diane Amirault, Andrew Boyne, Pierre Laporte, Julie McKnight, François Shaffer and Peter Thomas of the Canadian Wildlife Service and Dr. Stephen Flemming of Parks Canada.

General results and discussion

The regional banding program has proven to be one of the most comprehensive and ambitious efforts to date aimed at identifying demographic parameters for the entire eastern Canada population of Piping Plovers, encompassing five provincial jurisdictions. Detailed analyses of banding results and impacts are being published elsewhere (e.g. Amirault et al. 2006, Calvert et al. 2006).

In general, the banding protocol was effective in obtaining the desired information while minimizing overall impact on the regional Piping Plover population. A total of 1069 trapping attempts, including 606 individual nests (some nests had more than one capture attempt) and 206 broods, were made throughout the research program, with a high success rate: >85% for capture attempts at nests and 99% for capture of broods (Table 3). Follow-up observations by banders and nest monitors indicate that impacts on nesting birds and their productivity were very low. For example, hatching and fledging success for family units where banding occurred were comparable to overall regional productivity estimates (Amirault, unpublished data). Nest abandonment rates were also well within the overall regional range.

Table 3. Comparison of capture success rates using the box and modified Weller traps.

	No. Capture Attempts (Nests)	No. Capture			No. Attempts to Capture Broods
		Attempts using box trap		Attempts using modified Weller trap	
		No. Capture	Attempts using box trap	Attempts using modified Weller trap	
Successful	741	66 (76%)		675 (87%)	205
Unsuccessful	122	21 (24%)		101 (13%)	1
Total	863	87		776	206

Piping Plover banding research coordinators across North America have been challenged with selecting bands that would be appropriate for their studies while minimizing the risk of band-related injuries. This species is naturally prone to leg injuries and certain band types may increase this risk (Lingle et al. 1999). Over the course of this study, injuries were observed in a small number of birds banded with the tall anodized aluminium colour bands (Amirault et al. 2006). Once the problem was identified, all banding with these

markers ceased and attempts were made to remove as many bands of this type as possible. Although their colour did not fade, sand abrasion caused anodized aluminium bands to wear down, resulting in eventual total colour loss. This type of colour band should not be used on Piping Plovers or other shorebird species as they are not only ineffective for long term colour retention but also may cause leg injuries.

The banding study was a success because of the time spent to develop an effective banding protocol, based on published literature and experiences of other jurisdictions, and it received broad support from wildlife agencies in the region, were the keys to this successful banding program to provide the basis for a research initiative. The field work associated with this study has been completed and the data analysis and publication of results is ongoing. The results of this research will provide the science necessary to guide the development of future conservation strategies.

After the initial banding of the first bird in 1991, the Eastern Canada Piping Plover Banding Program began in 1992.

In 1992, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1993, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1994, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1995, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1996, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1997, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1998, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 1999, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 2000, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

In 2001, 100 piping plovers were banded in Quebec, Ontario, and Nova Scotia.

Appendix 2. Protocol for addressing Piping Plover mortality or injuries

In a twenty-year study of Piping Plovers on the United States Atlantic Coast, Wilcox (1959) reported no fatalities due to trapping, and recent North American banding efforts have resulted in negligible band-related fatalities or injuries. Therefore, little mortality or injury was anticipated as a result of capturing and handling plovers in the banding study in eastern Canada. However, because of the sensitivity of this declining population to increased mortality and reduced productivity, the following protocol was developed to address events where birds were inadvertently injured or killed.

Any Piping Plover found dead or injured, particularly when the mortality or injury was suspected of being linked to the banding study, was to be reported immediately to Diane Amirault, Canadian Wildlife Service. After assessing the circumstances, a decision would be made on whether to suspend or modify the remainder of the study.

An attempt was to be made to capture any injured bird to determine the cause and extent of the injury, and any link to banding. If the band(s) appeared to be causing the injury, the band(s) were to be removed. A detailed description of the injury was to be made for future reference, and injured limbs photographed. All possible attempts were to be made to rehabilitate injured individuals. Severely injured individuals were to be euthanized using cervical dislocation. The behaviour and survival of injured birds that could not be captured, or were captured and released, were to be monitored closely.

Any banded plovers that died were to be examined by Dr. Scott McBurney at the Atlantic Veterinary College (AVC) in Charlottetown, Prince Edward Island, in order to determine the cause of death and possible relationships to banding. All dead Piping Plovers were to be retrieved, as they could yield valuable information through post-mortem analysis on diet, parasites of the gastro-intestinal tract or lungs, inclusion in DNA studies to determine genetic relationships and potential archiving in a tissue storage bank at an appropriate facility.

Post-mortem examinations were conducted on fresh specimens whenever possible. Dead birds were transported directly to the AVC, ensuring that refrigeration did not exceed 48 hours. If it was not possible to submit specimens within a short time after death, they were frozen for future analysis. All specimens were shipped on ice or frozen. Specimens submitted to the AVC were accompanied by relevant information on nesting status and other history. Dr. McBurney was to be notified prior to submitting samples to the AVC.
