

Climatic Perspectives

February 5 to 11, 1990

A weekly review of Canadian climate

Vol.12 No.6

Prolonged mild spell over the Great Lakes

Relatively mild temperatures have prevailed over Ontario and southwestern Quebec during the last six weeks. In contrast, a bitterly cold Arctic air mass spread across and now has a firm grip on the Yukon and Northwest Territories.

A persistent southwesterly circulation has recurrently fed unseasonably mild air from the Gulf States towards the Great Lakes Basin. Since the beginning of the year, this pattern has resulted in a stretch of well-above-normal mean weekly temperatures. Numerous new daily high temperature records have been set in both Ontario and Quebec. On a number of occasions, daytime highs in southern Ontario have soared to the double digits.

The relatively mild, near-freezing temperatures benefitted attendance at the Québec Winter Carnival, but the warm spring-like weather during Ottawa's Winterlude, which occurred the same week, frustrated organizers and participants alike, as some outdoor events had to be restricted or cancelled because of the unusual thaw.

Arctic cold

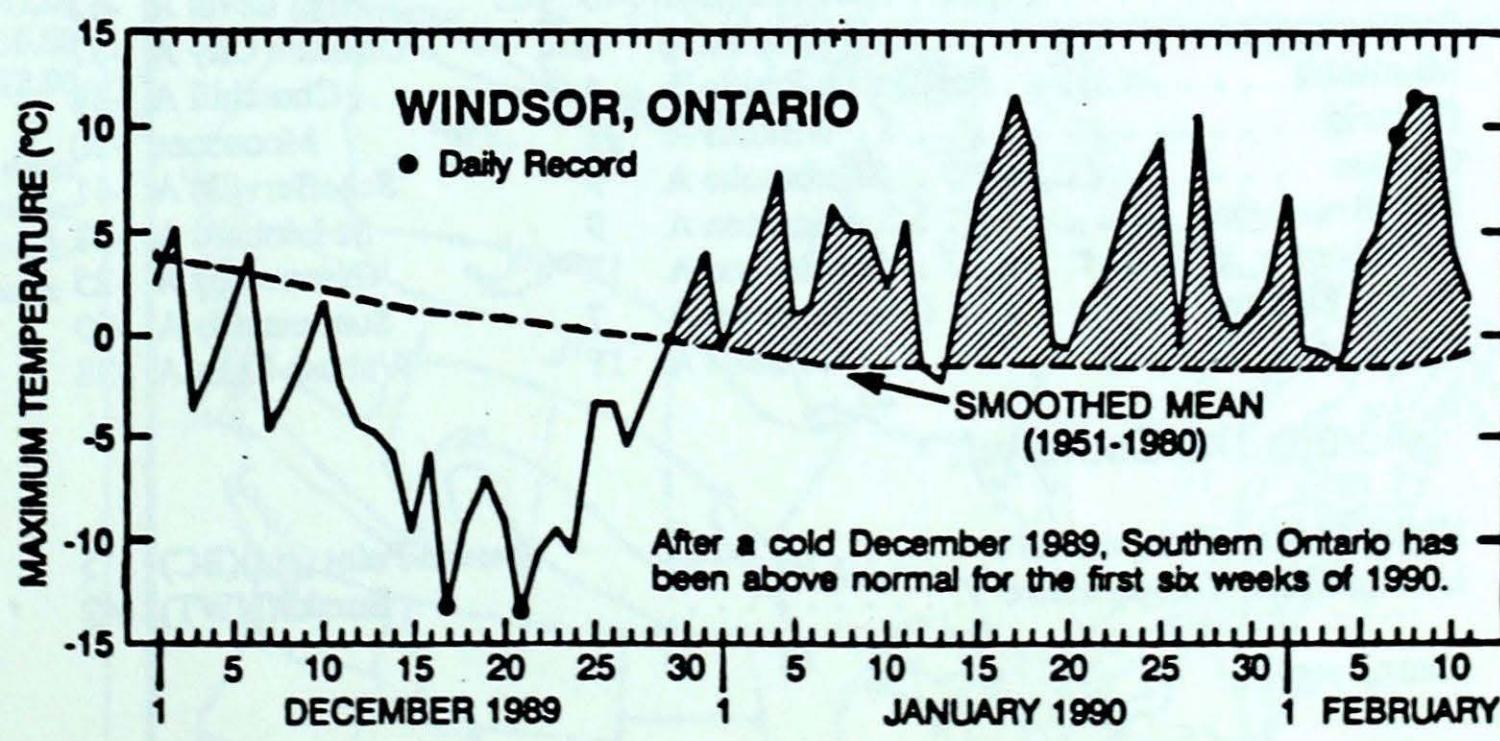

Inhabitants residing in northwestern Canada are now making up for the nearly continuous stretch of warmer-than-normal months that they have enjoyed since April 1989. During this lengthy period, only November 1989 averaged below normal

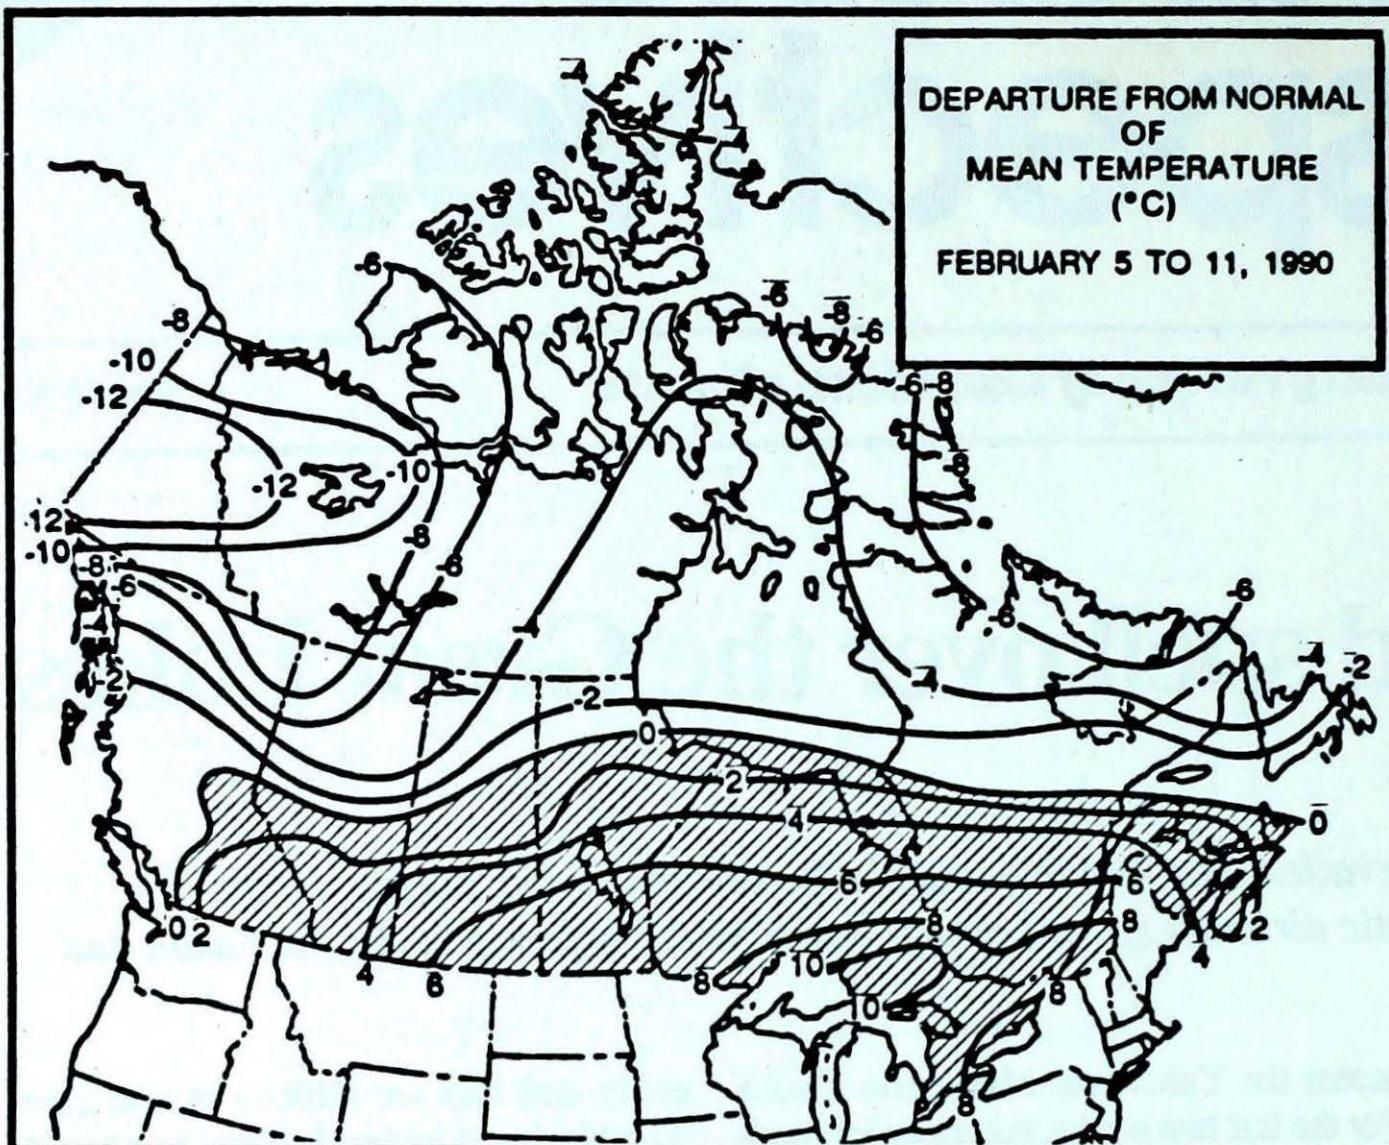

across the Yukon and Mackenzie district. For the last two weeks, minimum temperatures have been bottoming out at the mid minus 50s. For twenty consecutive days the thermometer at Old Crow, in the central Yukon, did not rise above -40°C. In the Northwest Territories, north of Great Bear Lake, temperatures have been reported as low as minus sixty. At these extreme temperatures even the slightest breeze makes it very difficult and dangerous to work outdoors, and thawing frozen plumbing is a common pastime. Normally pliable objects become brittle, snap or even shatter, automobile components crack or break

easily, and cars are difficult to start even with block and battery heaters. As a result, many vehicles are left running continuously all day.

Most of Canada to remain below normal

For the week of February 19, below-normal temperatures are expected for all of the country except the southern half of Ontario and southwestern Quebec. The coldest parts of the country are likely to be the Yukon, Labrador and northern Quebec.

Weekly normal temperatures (°C)

Climatic Perspectives is a weekly publication (disponible aussi en français) of the Canadian Climate Centre, Atmospheric Environment Service, 4905 Dufferin St., Downsview, Ontario, Canada M3H 5T4

 (416) 739-4438/4436

The purpose of the publication is to make topical information available to the public concerning the Canadian Climate and its socio-economic impact.

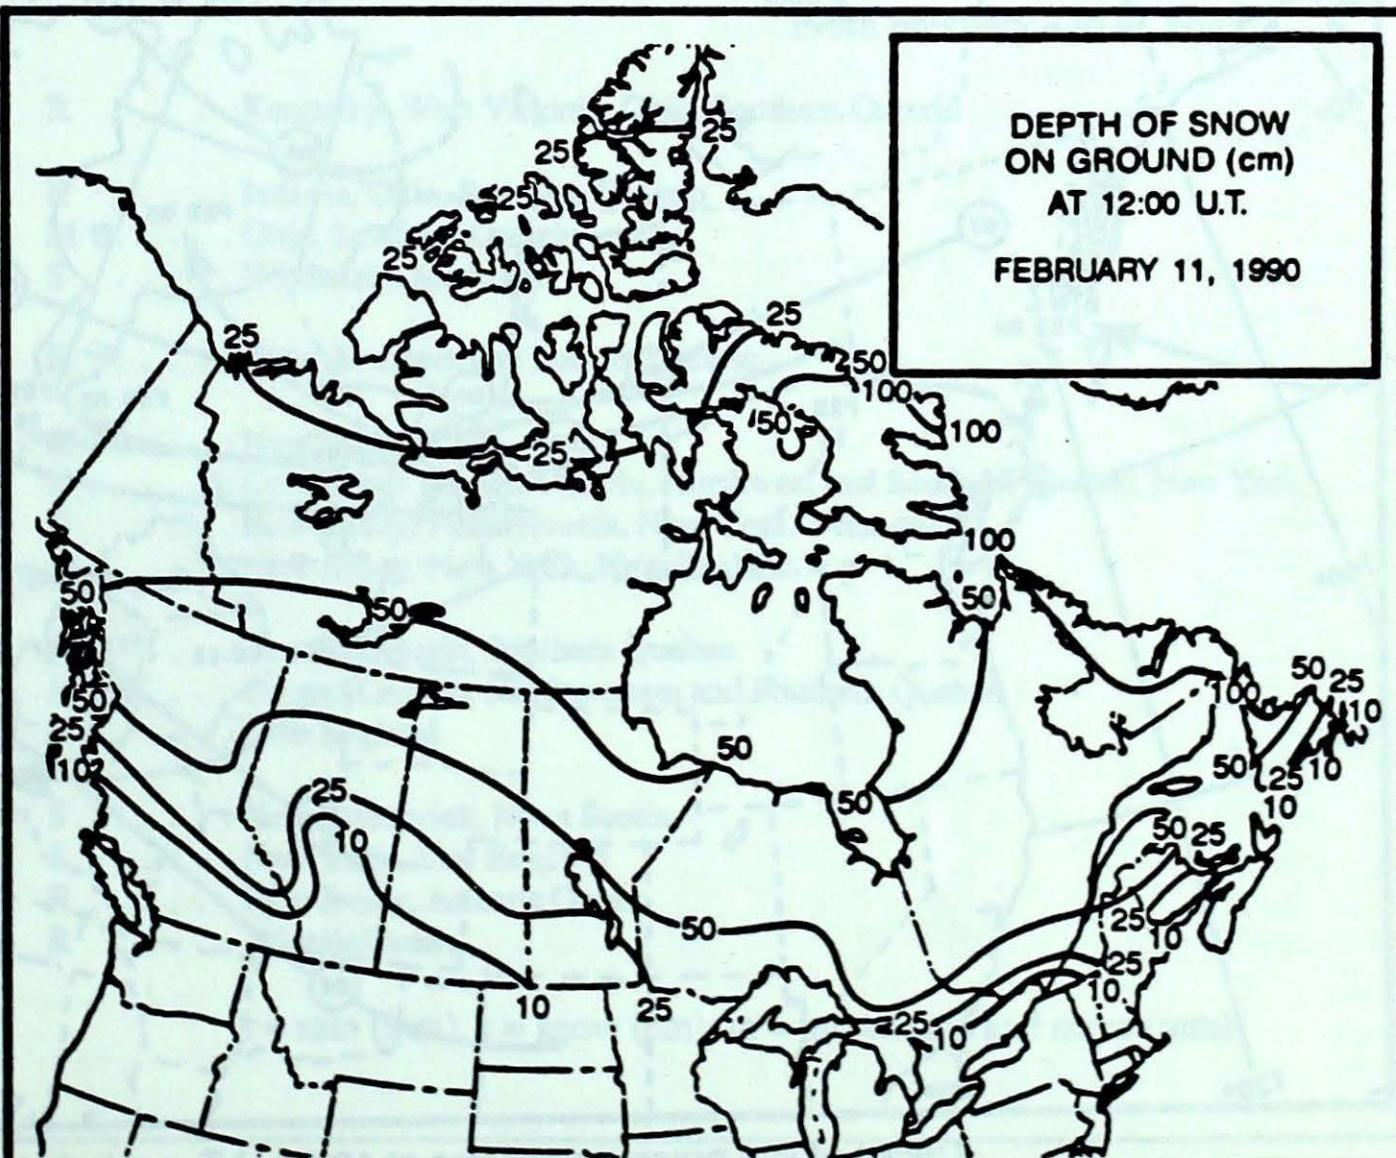

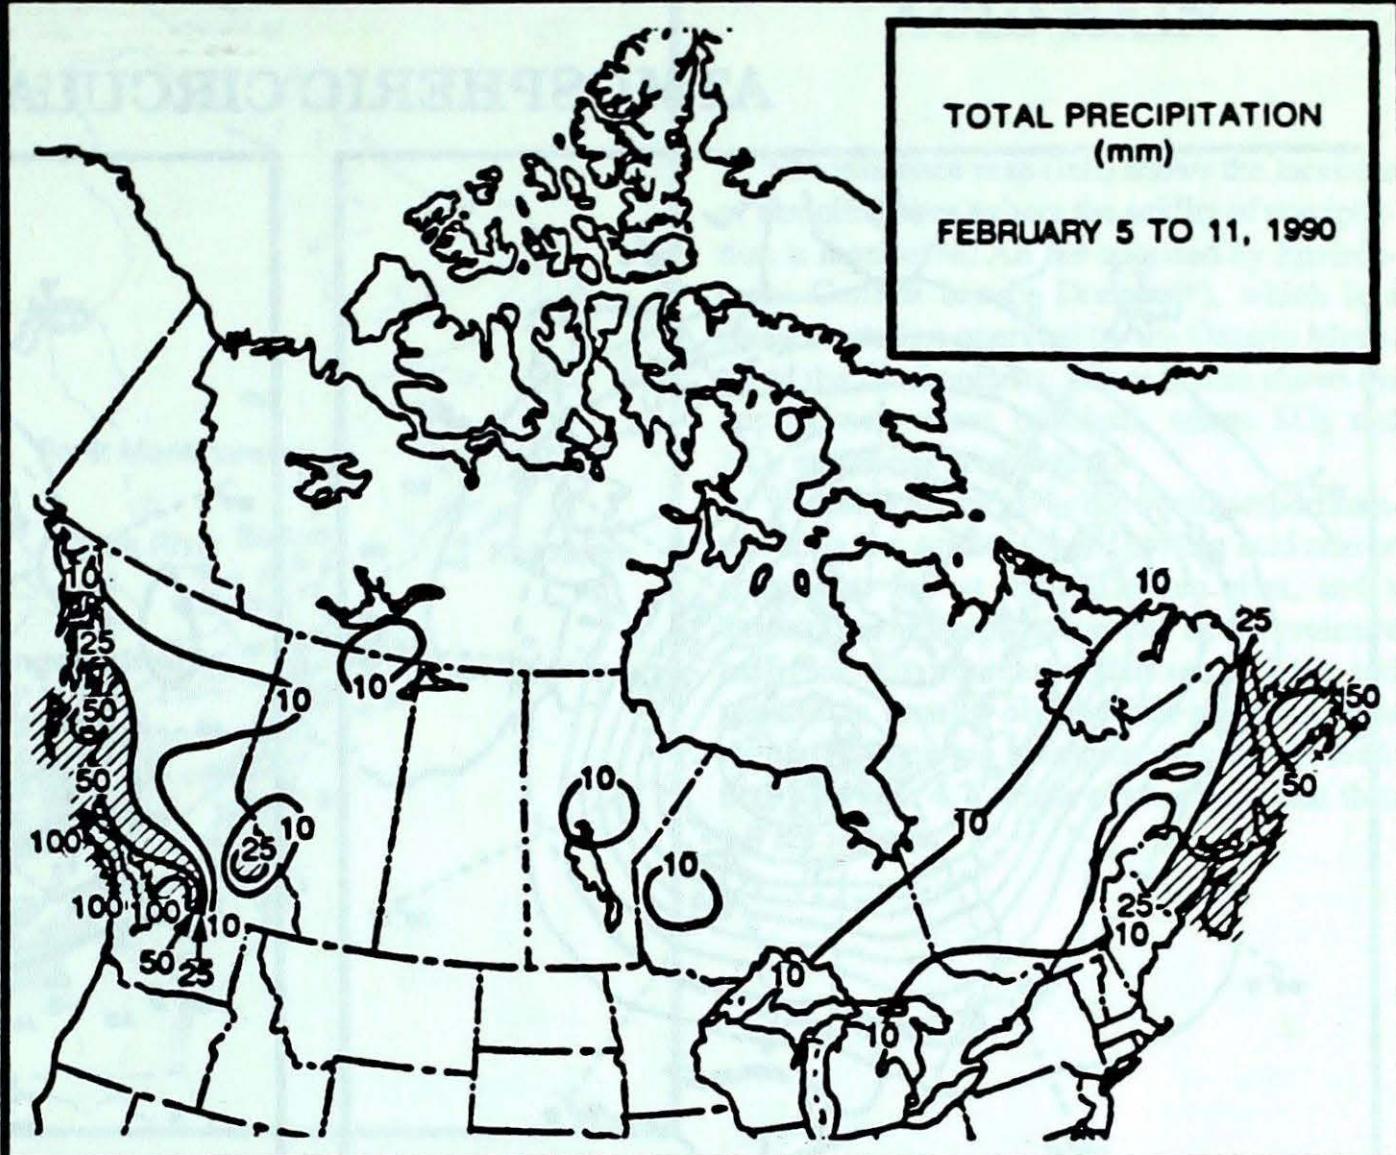

The data in this publication are based on unverified reports from approximately 225 Canadian synoptic weather stations. Information concerning climatic impacts is gathered from AES contacts with the public and from the media. Articles do not necessarily reflect the views of the Atmospheric Environment Service.

Annual Subscriptions

ACID RAIN

The reference map (left) shows the locations of sampling sites, where the acidity of precipitation is monitored. All are operated by Environment Canada except Dorset (*), which is a research station operated by the Ontario Ministry of the Environment. The map also shows the approximate areas (shaded), where SO₂ and NO_x emissions are greatest.

The table below gives the weekly report summarizing the acidity (or pH) of the acid rain or snow that fell at the collection sites, and a description of the path travelled by the moisture laden air. Environmental damage to lakes and streams is usually observed in sensitive areas regularly receiving precipitation with pH readings less than 4.7, while pH readings less than 4.0 are serious.

| Site | day | pH | amount | air path to site |
|-----------------------------|-----|-----|--------|--|
