Feb. 25 to Mar. 3, 1991

A weekly review of Canadian climate and water

Vol. 13 No. 09

Late winter storms affect much of Canada

Although spring does not arrive officially until the latter part of March, in southern British Columbia it usually seems to make its presence felt one to two months earlier than in the rest of Canada.

A stretch of balmy spring-like weather in British Columbia, came to an abrupt end on March 1 and 2, as cold Arctic air and a late winter snow storm moved across the province. In Victoria, where spring flowers were out in bloom, it all seemed like a bad dream, as 10 to 15 centimetres of snow piled up on the ground. Outside the city, as much as 35 cm of snow fell, causing road closures. On B.C.'s lower mainland this was the forth major snowfall of the season. The winter storm dumped between 15 to 25 centimetres of snow; well in excess of the usual March snowfall of approximately 7 cm. A multi-car pileup on the Trans Canada Highway near Chilliwack was attributed to the more than 40 cm of snow that fell in the area accompanied by strong winds. Snowfalls in the interior valleys varied widely. Hope, in the eastern end of the Fraser Valley, received 33 cm, more than twice the normal for the month of March. The snow is unlikely to affect gardens and flowers already in bloom, as it is usually the low temperatures that do the damage.

On the Prairies, March ushered in like a lion as Arctic air spilled southwards accompanied by drifting and blowing snow. Temperatures dipped to the minus twenties and thirties, causing concern for ranchers, as calving season is underway.

Freezing rain coats eastern Canada

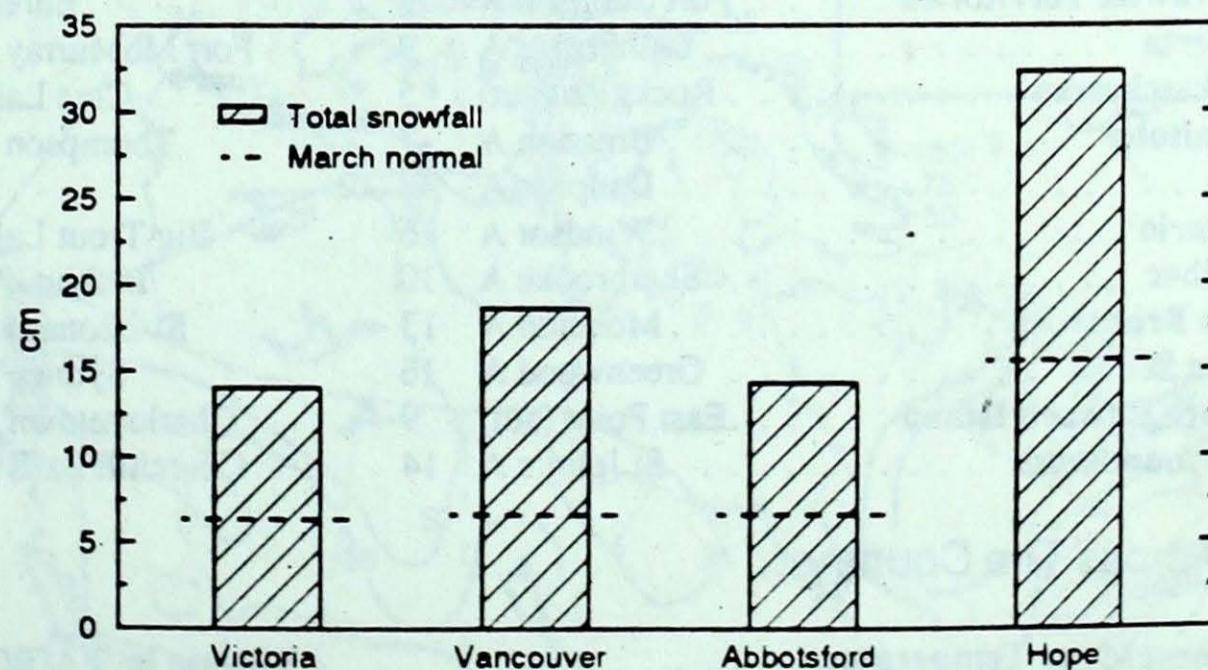

Following two days of record mild weather, a large area of freezing rain developed over the Great Lakes Basin and spread eastwards into Quebec and the Maritimes over the weekend. In Ontario, the freezing rain started on the evening of the 2nd and redeveloped the next day, coating exposed objects with one to two centimetres of ice and ice pellets. In Quebec, the storm began as freezing rain late on March 3, and changed over to snow the next day, while in the Maritimes, residents woke up to a major ice storm that brought down trees and power lines. Freezing rain episodes in eastern Canada are not unusual. On average, freezing precipitation can occur 10 to 20 days of

the year. The mean number of days it occurs during March varies between 1 and 3, but this can be observed more frequently in some areas of Nova Scotia and Newfoundland.

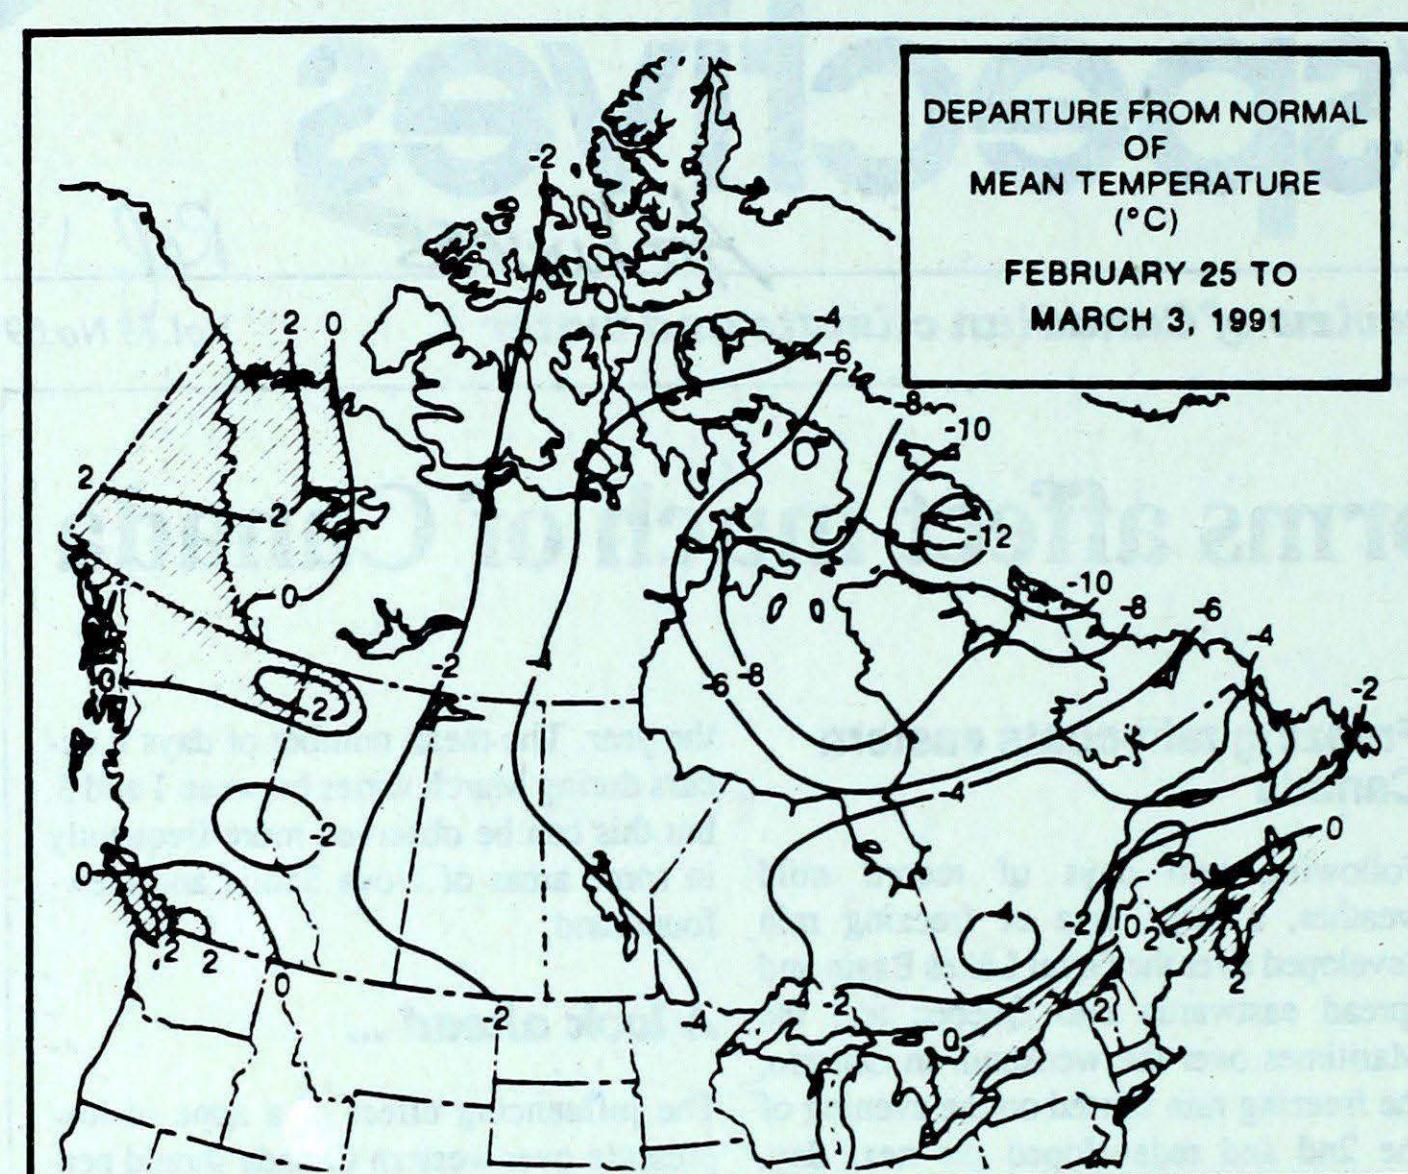

A look ahead ...

The influencing effect of a zone of low pressure over western Canada should persist for the week of March 11. As a result, cold Arctic air will dictate the temperatures from the Yukon through B.C. and into Saskatchewan. In southern Ontario, Quebec and the Atlantic Provinces the temperatures are expected to be above normal. Manitoba and northwestern Ontario will experience near normal temperatures.

Total snowfall for March 1 - 2, 1991

Snowfalls during the first few days of March on British Columbia's south coast and southern Vancouver Island have exceeded the average snowfall for the month.

Climatic Perspectives is a weekly publication (disponible aussi en français) of the Canadian Climate Centre, Atmospheric Environment Service, 4905 Dufferin St., Downsview, Ontario, Canada M3H 5T4

☎ (416) 739-4438/4436

The purpose of the publication is to make topical information available to the public concerning the Canadian Climate and its socio-economic impact.

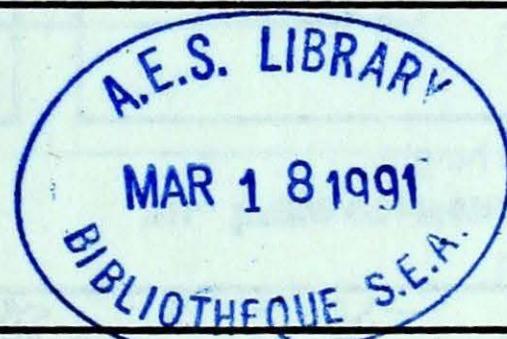

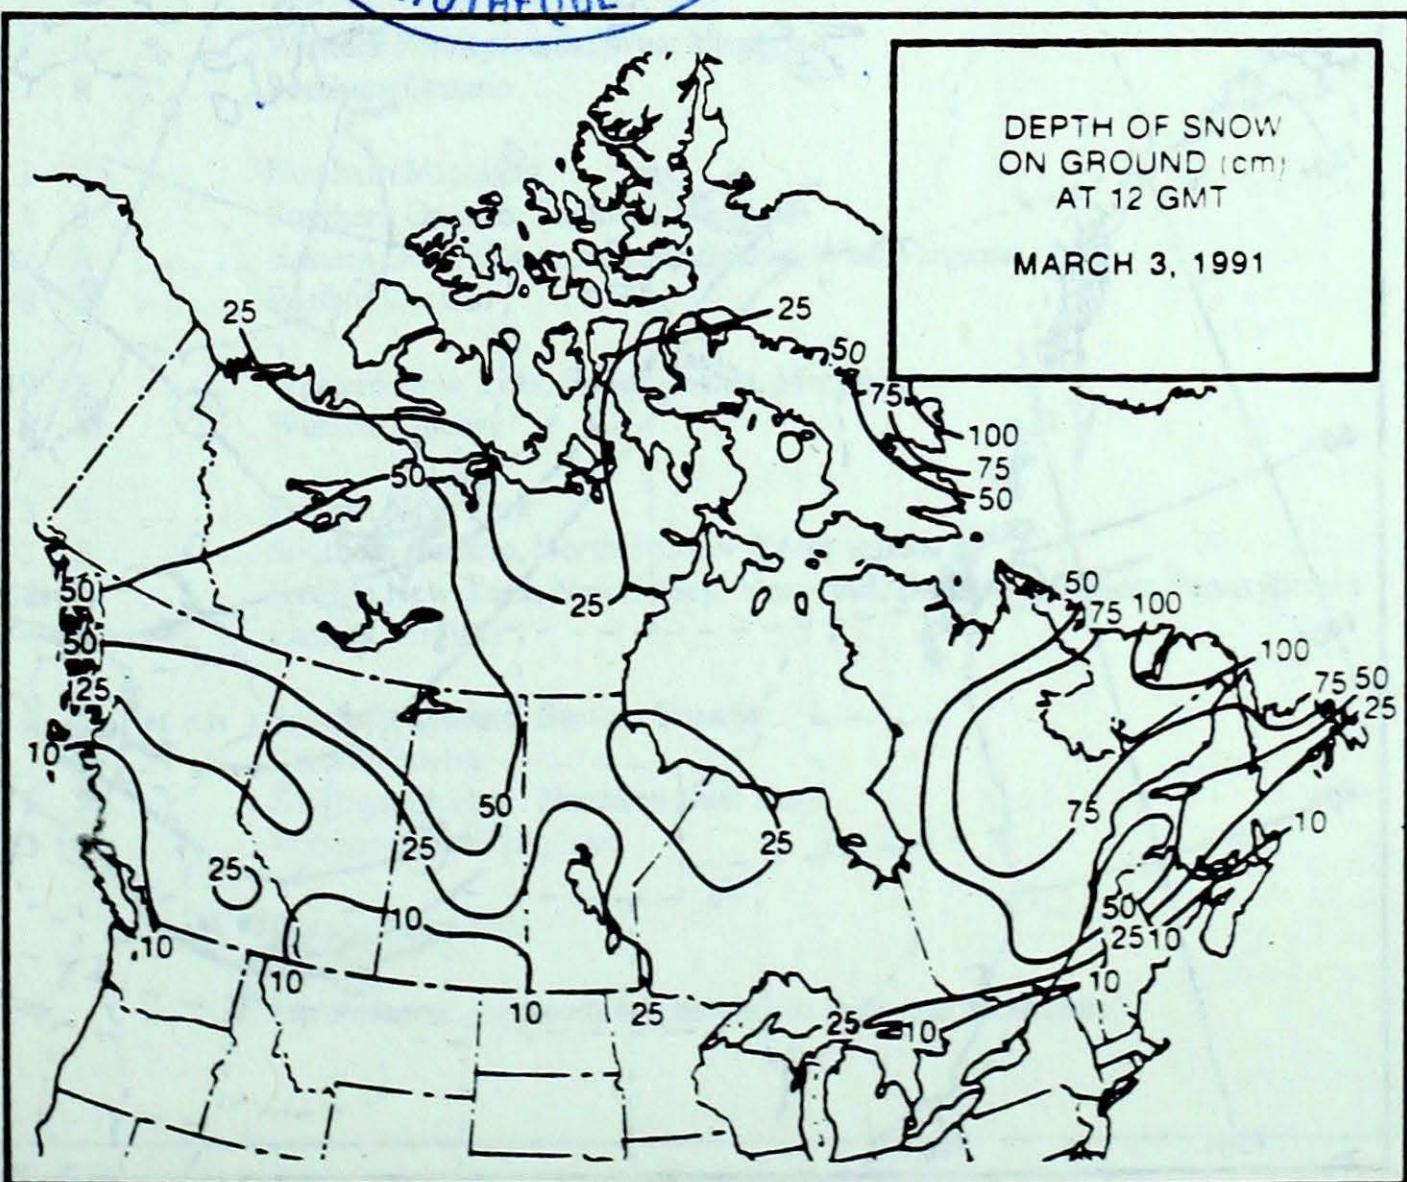

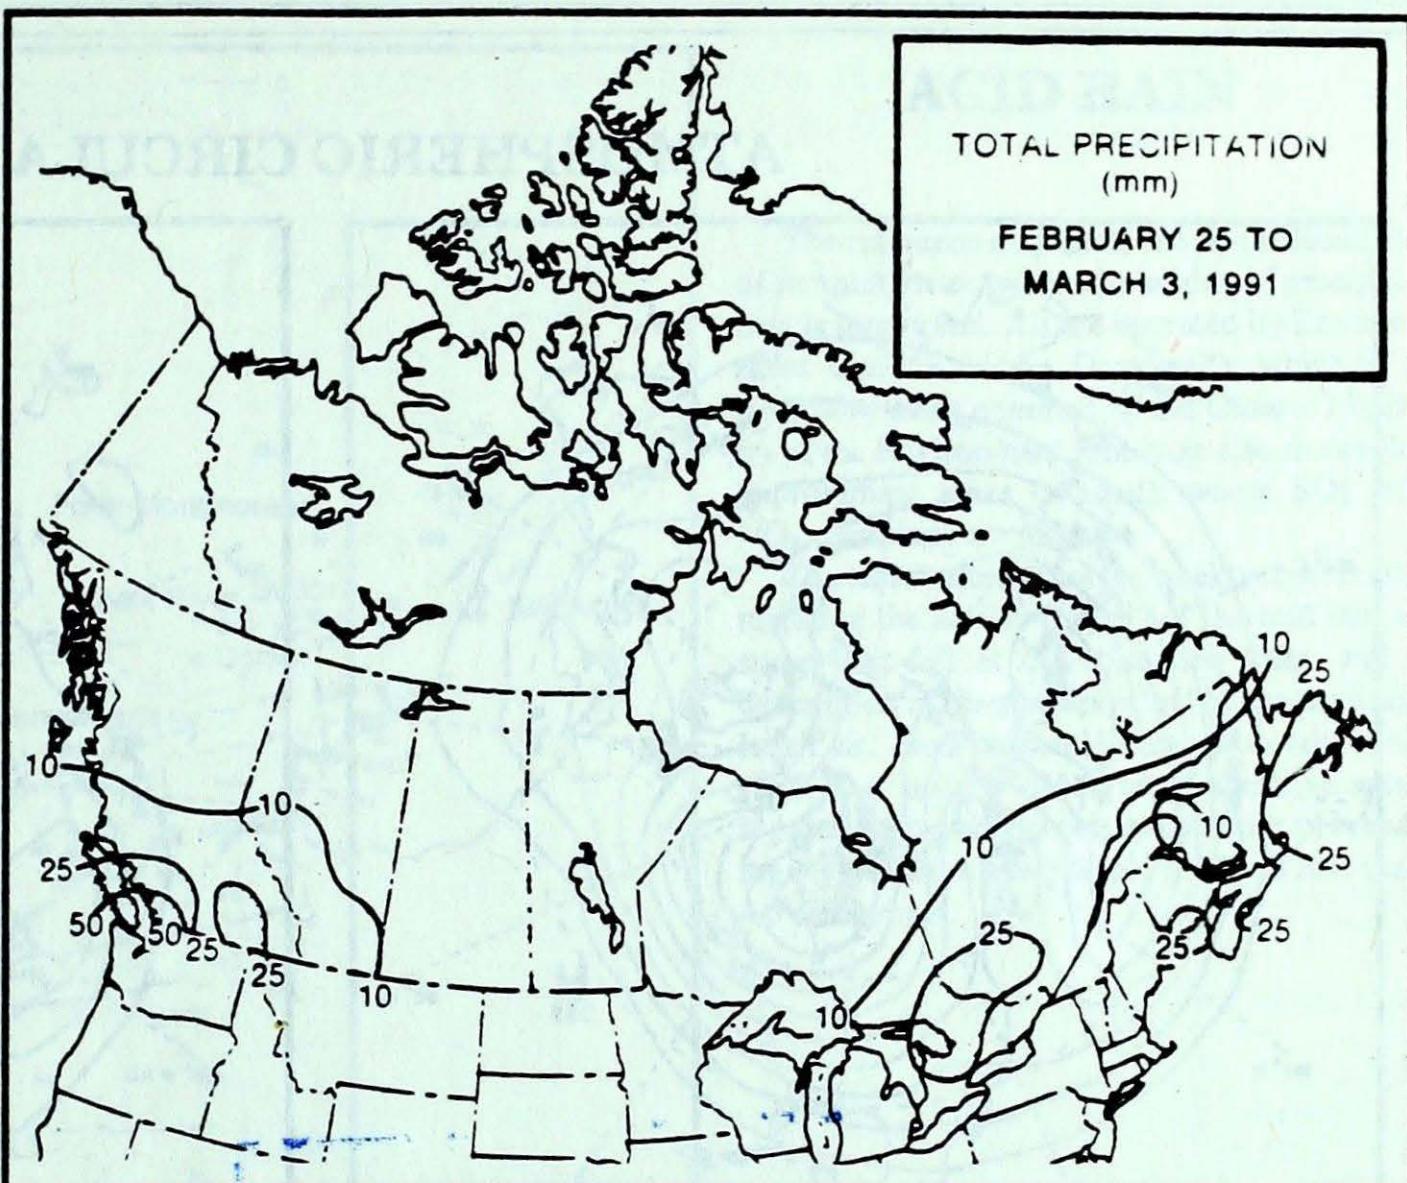

The data in this publication are based on unverified reports from approximately 225 Canadian synoptic weather stations. Information concerning climatic impacts is gathered from AES contacts with the public and from the media. Articles do not necessarily reflect the views of the Atmospheric Environment Service.

ATMOSPHERIC CIRCULATION

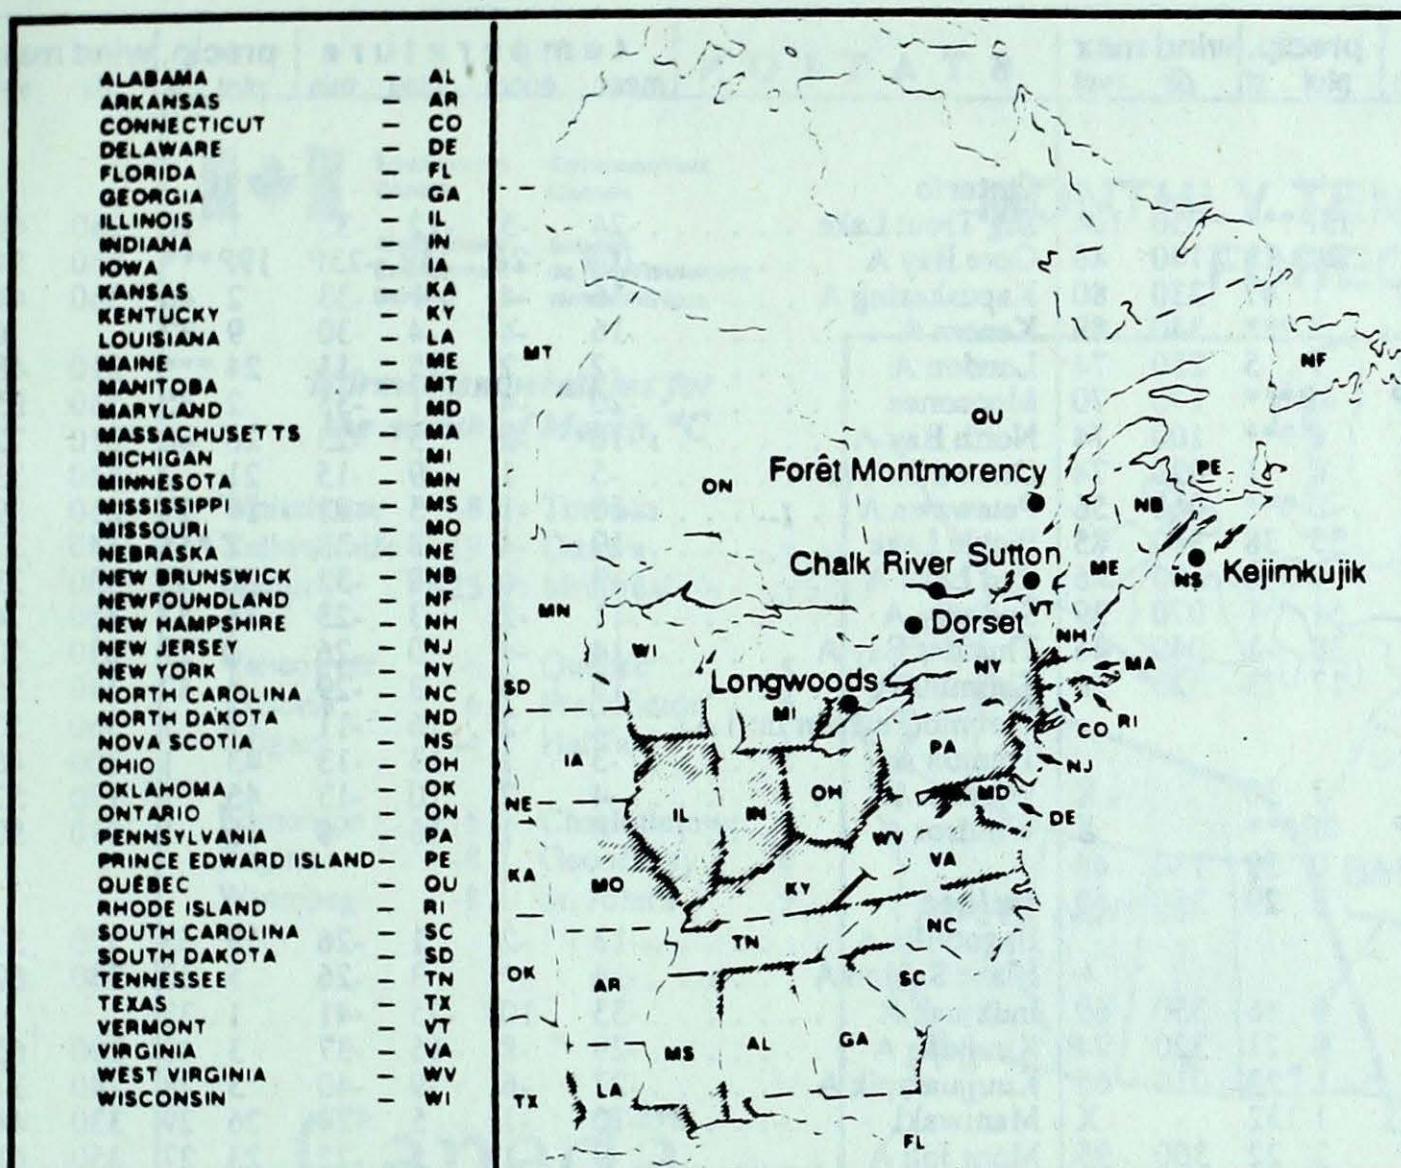

Mean geopotential height
50-kPa level (10-decametre intervals)

Mean geopotential height anomaly
50-kPa level (10-decametre intervals)

Tracks of low pressure centres at 12:00 U.T. each day during the period.

ACID RAIN

The reference map (left) shows the locations of sampling sites, where the acidity of precipitation is monitored. All are operated by Environment Canada except Dorset (*), which is a research station operated by the Ontario Ministry of the Environment. The map also shows the approximate areas (shaded), where SO₂ and NO_x emissions are greatest.

The table below gives the weekly report summarizing the acidity (or pH) of the acid rain or snow that fell at the collection sites, and a description of the path travelled by the moisture laden air. Environmental damage to lakes and streams is usually observed in sensitive areas regularly receiving precipitation with pH readings less than 4.7, while pH readings less than 4.0 are serious.
