# Climatic Perspectives

March 2 to 8, 1992

**A weekly review of Canadian climate and water**

Vol. 14 No. 10

## Concern over moisture in the Prairies

The southern parts of Alberta and Saskatchewan have been experiencing a dry winter. Long periods of above freezing temperatures, since late December, have caused an early loss of snow cover, and the general outlook is for temperatures to be above normal over the next few weeks. This could bring about an early spring run-off of even mountain-fed streams.

The mountain snowpack in southern Alberta is below average to average, and the Prairie Farm Rehabilitation Administration has expressed concern over farm water supplies in the drainage basins of the Milk (Missouri) River, and many of the tributaries of the South Saskatchewan River, where precipitation, since November, has been about half of the long term average. So far, most major irrigation water storage reservoirs are close to normal.

By contrast, northwestern Alberta and southern Manitoba have been wet, though there exists a drier zone extending from Lake Winnipeg to The Pas, and west beyond Nipawin, Sask. Central and northeastern Alberta, and northern Saskatchewan and Manitoba have had a near normal winter precipitation. The headwaters of the North Saskatchewan, the Athabasca and the Peace Rivers have normal to above normal snow cover accumulations, but the timing of melt may be important. The Athabasca is expected to discharge more than the usual volume of water, and if, when the freshet peaks, there is warm weather, rain or ice jamming on this northeasterly-flowing system, there could be flooding, and perhaps less water available later in the season.

Some meagre moisture was made available to central and southern Alberta during the week: first as dense fog from

lingering warm, moist air over snow cover on the 4th and 5th, and then from flurries, as a cold front moved south. The fog caused numerous flight delays at Edmonton, and there were a number of road accidents.

### Distant storm influences Maritimes

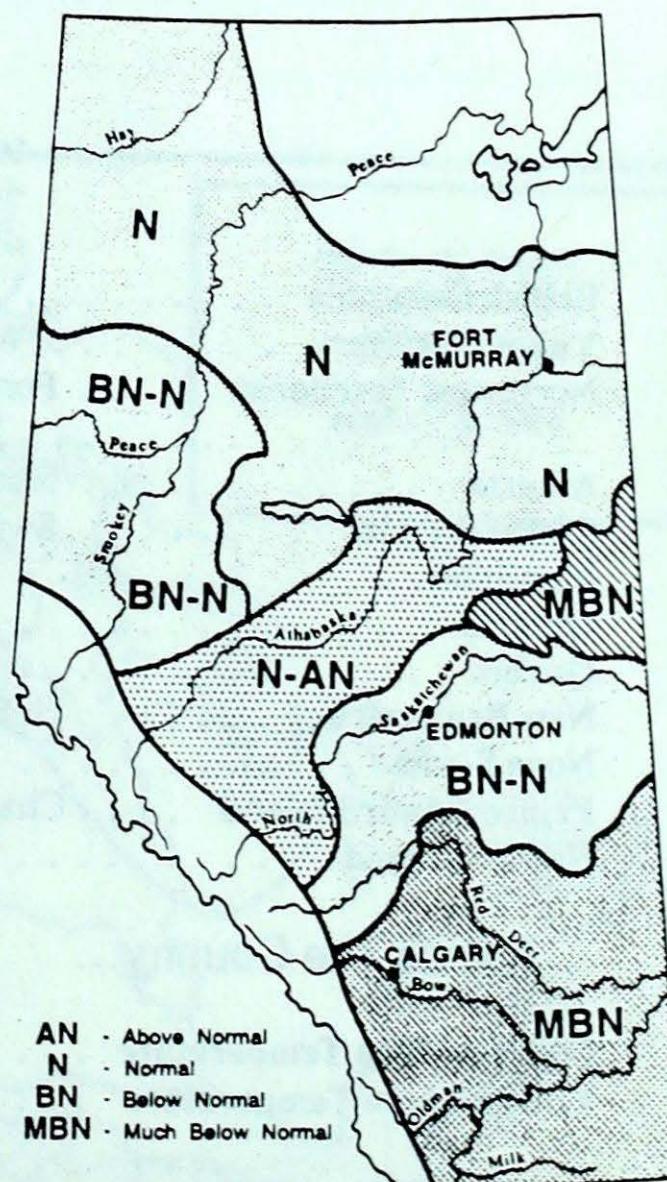

Albeit that the "eye" of the storm over Cape Cod, Mass. only reached the Atlantic shore of Nova Scotia on the 9th, there were massive downpours throughout the Atlantic region the previous day. Hart Island, near Canso, N.S., received 127 mm of rain on the 8th.

The tempest delivered an extensive assortment of precipitation, typical when the temperature dances around the freezing mark, ranging from snow, rain then to freezing rain and ice pellets. This caused some awfully slippery conditions, resulting in 35 car accidents in the Saint John, N.B. area. There were no serious injuries reported, even as driving became a bit treacherous when water, draining from residential yards, flooded local streets in the towns and cities of New Brunswick.

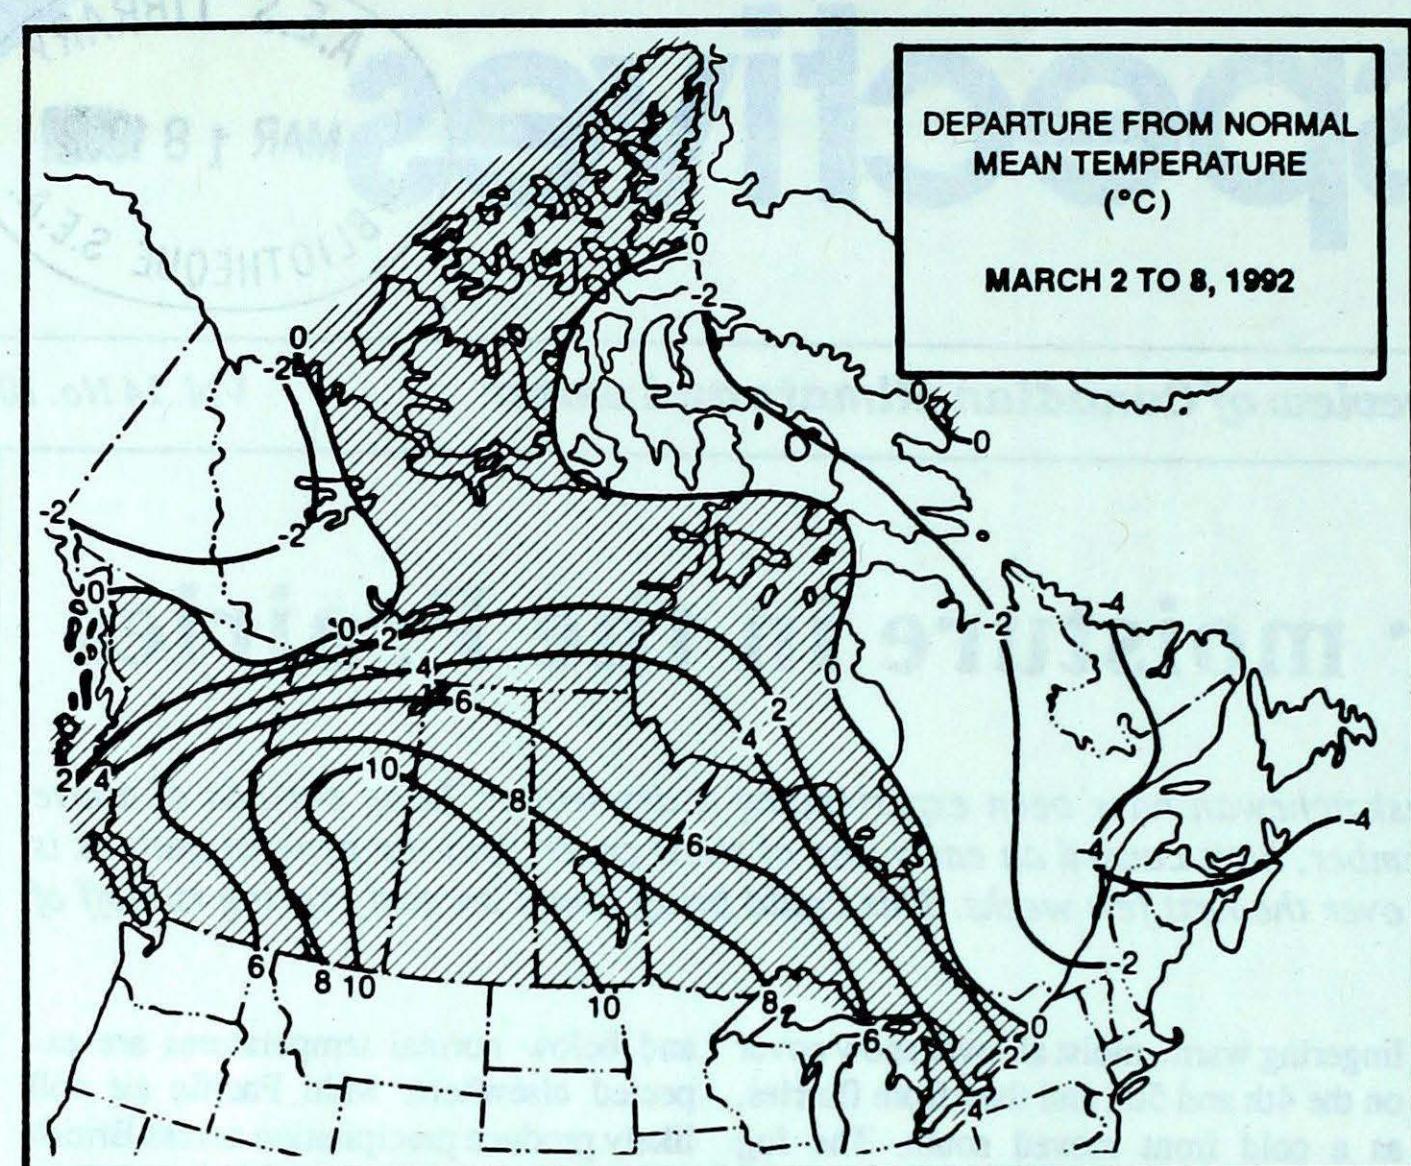

### A look ahead...

For the week of March 16, above normal temperatures are expected west of Ontario

and below normal temperatures are expected elsewhere. Mild Pacific air will likely produce precipitation across British Columbia, the Yukon, the Mackenzie District of the Northwest Territories and Alberta. As well, stormy weather is likely across the Atlantic provinces.

Spring runoff outlook, as of March 1, 1992.

**Climatic Perspectives** is a weekly publication (disponible aussi en français) of the Canadian Climate Centre, Atmospheric Environment Service, 4905 Dufferin St., Downsview, Ontario, Canada M3H 5T4

**Telephone** (416) 739-4438/4330

The purpose of the publication is to make topical information available to the public concerning the Canadian Climate and its socio-economic impact.

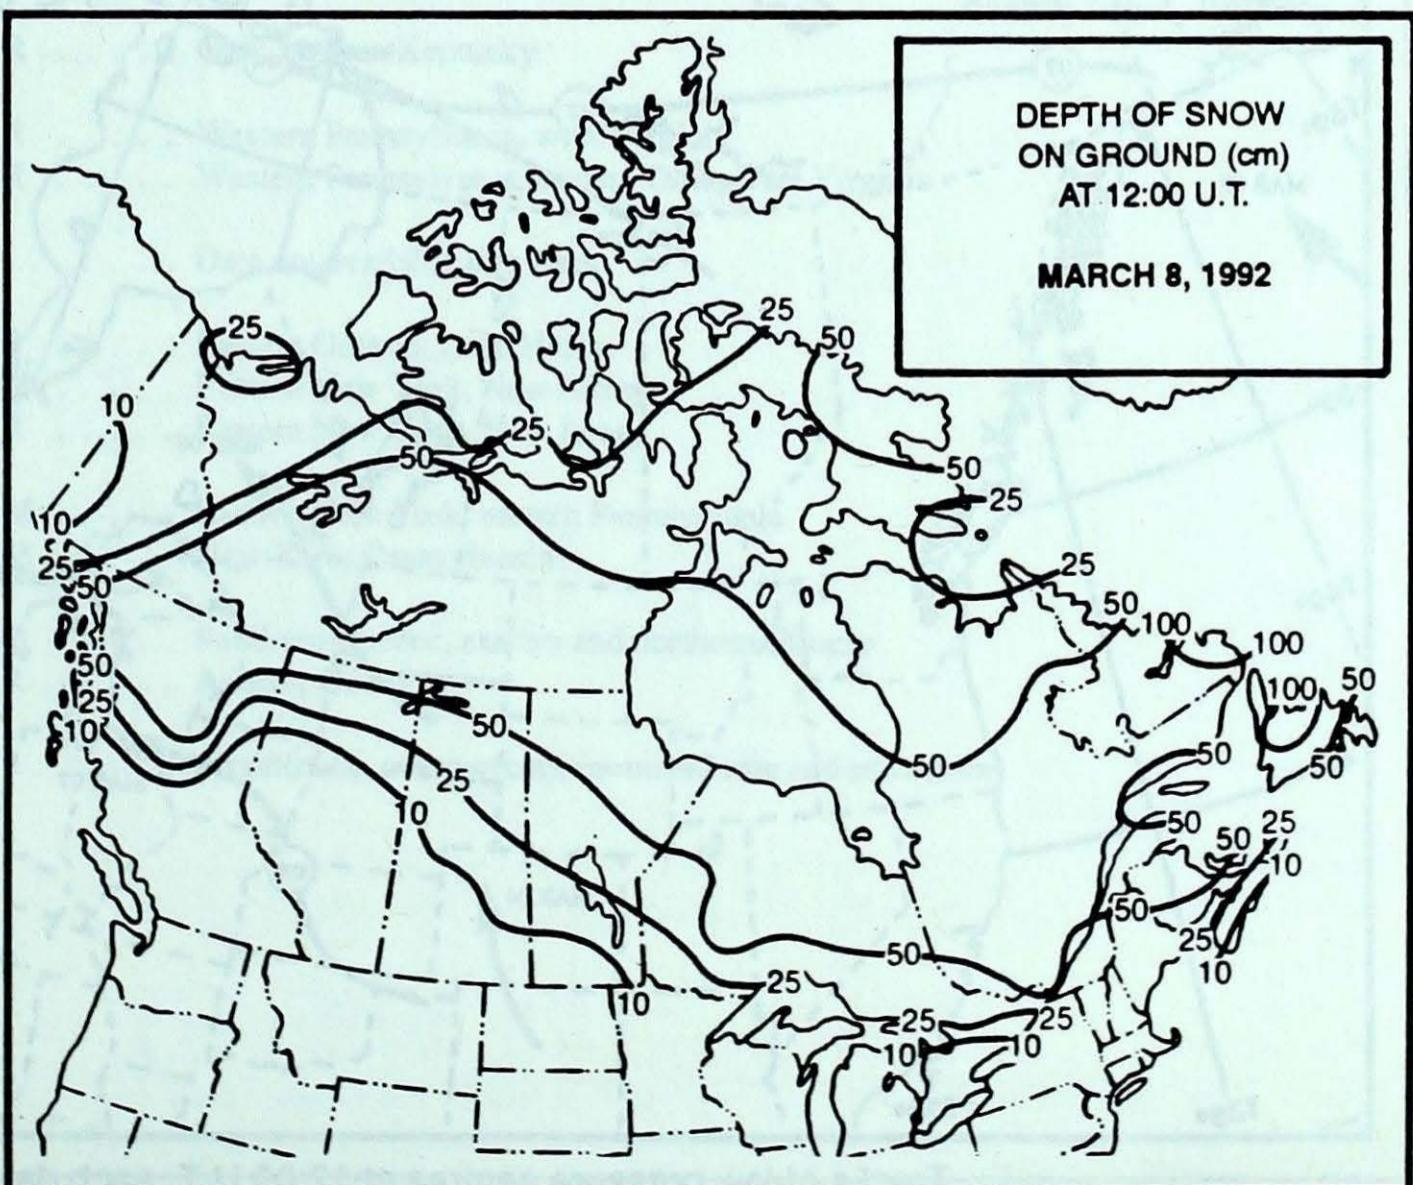

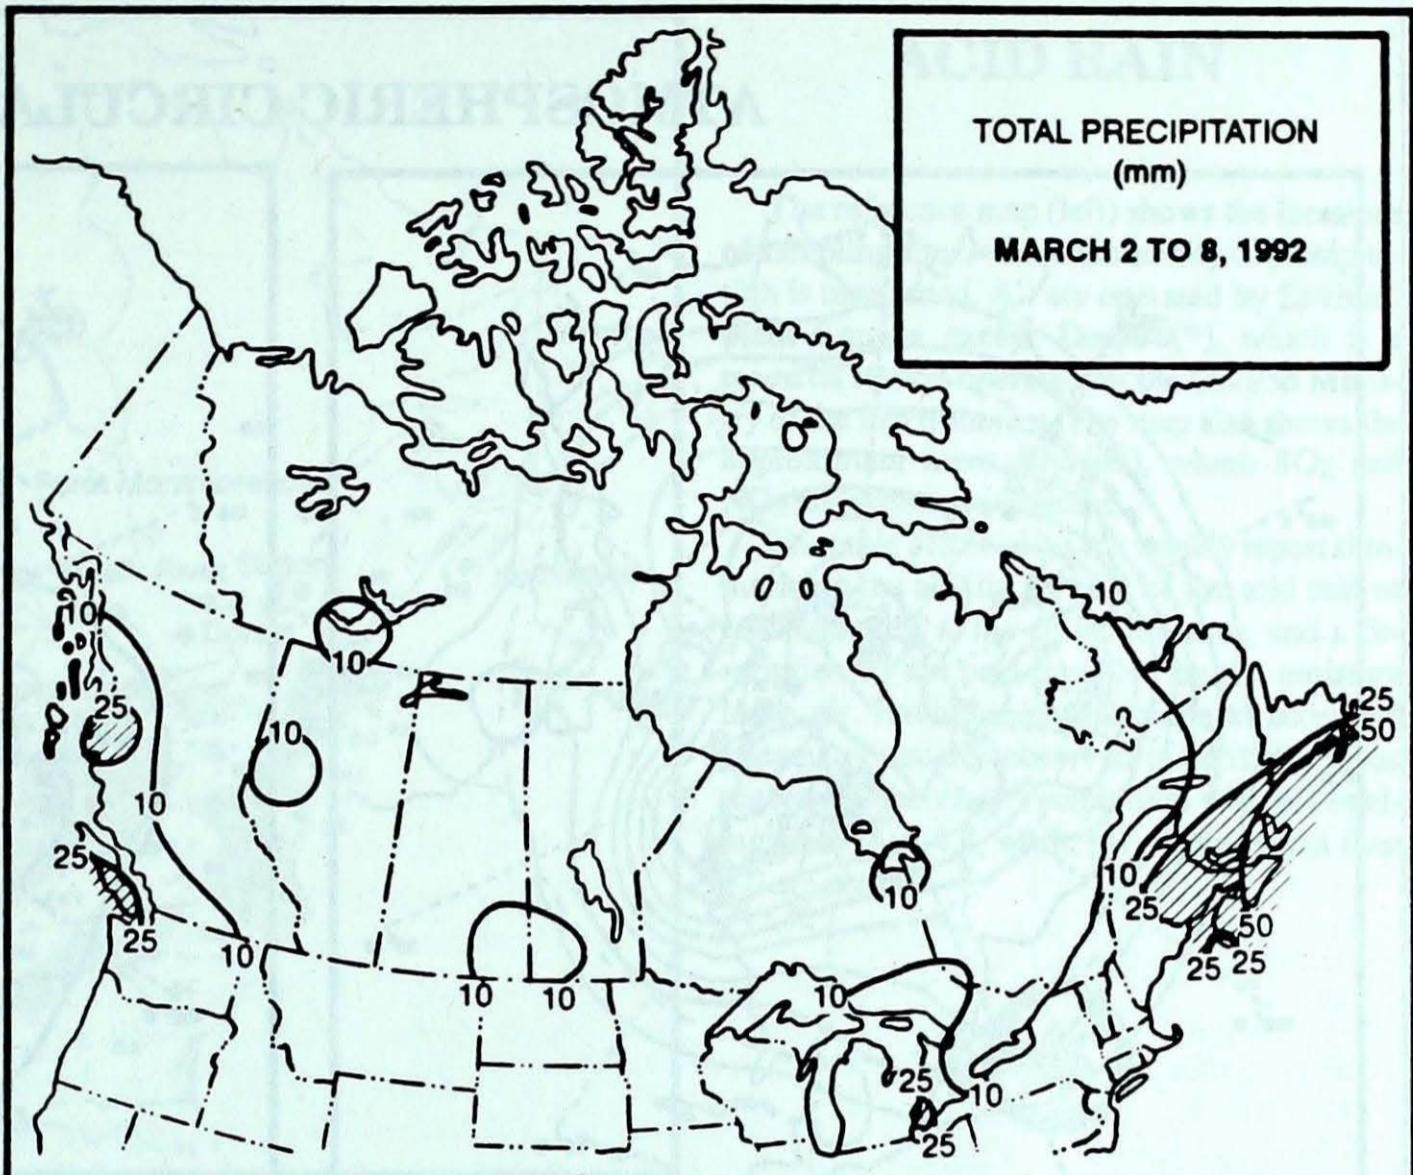

The data in this publication are based on unverified reports from approximately 225 Canadian synoptic weather stations. Information concerning climatic impacts is gathered from AES contacts with the public and from the media. Articles do not necessarily reflect the views of the Atmospheric Environment Service.

**Annual Subscriptions**

## ATMOSPHERIC CIRCULATION

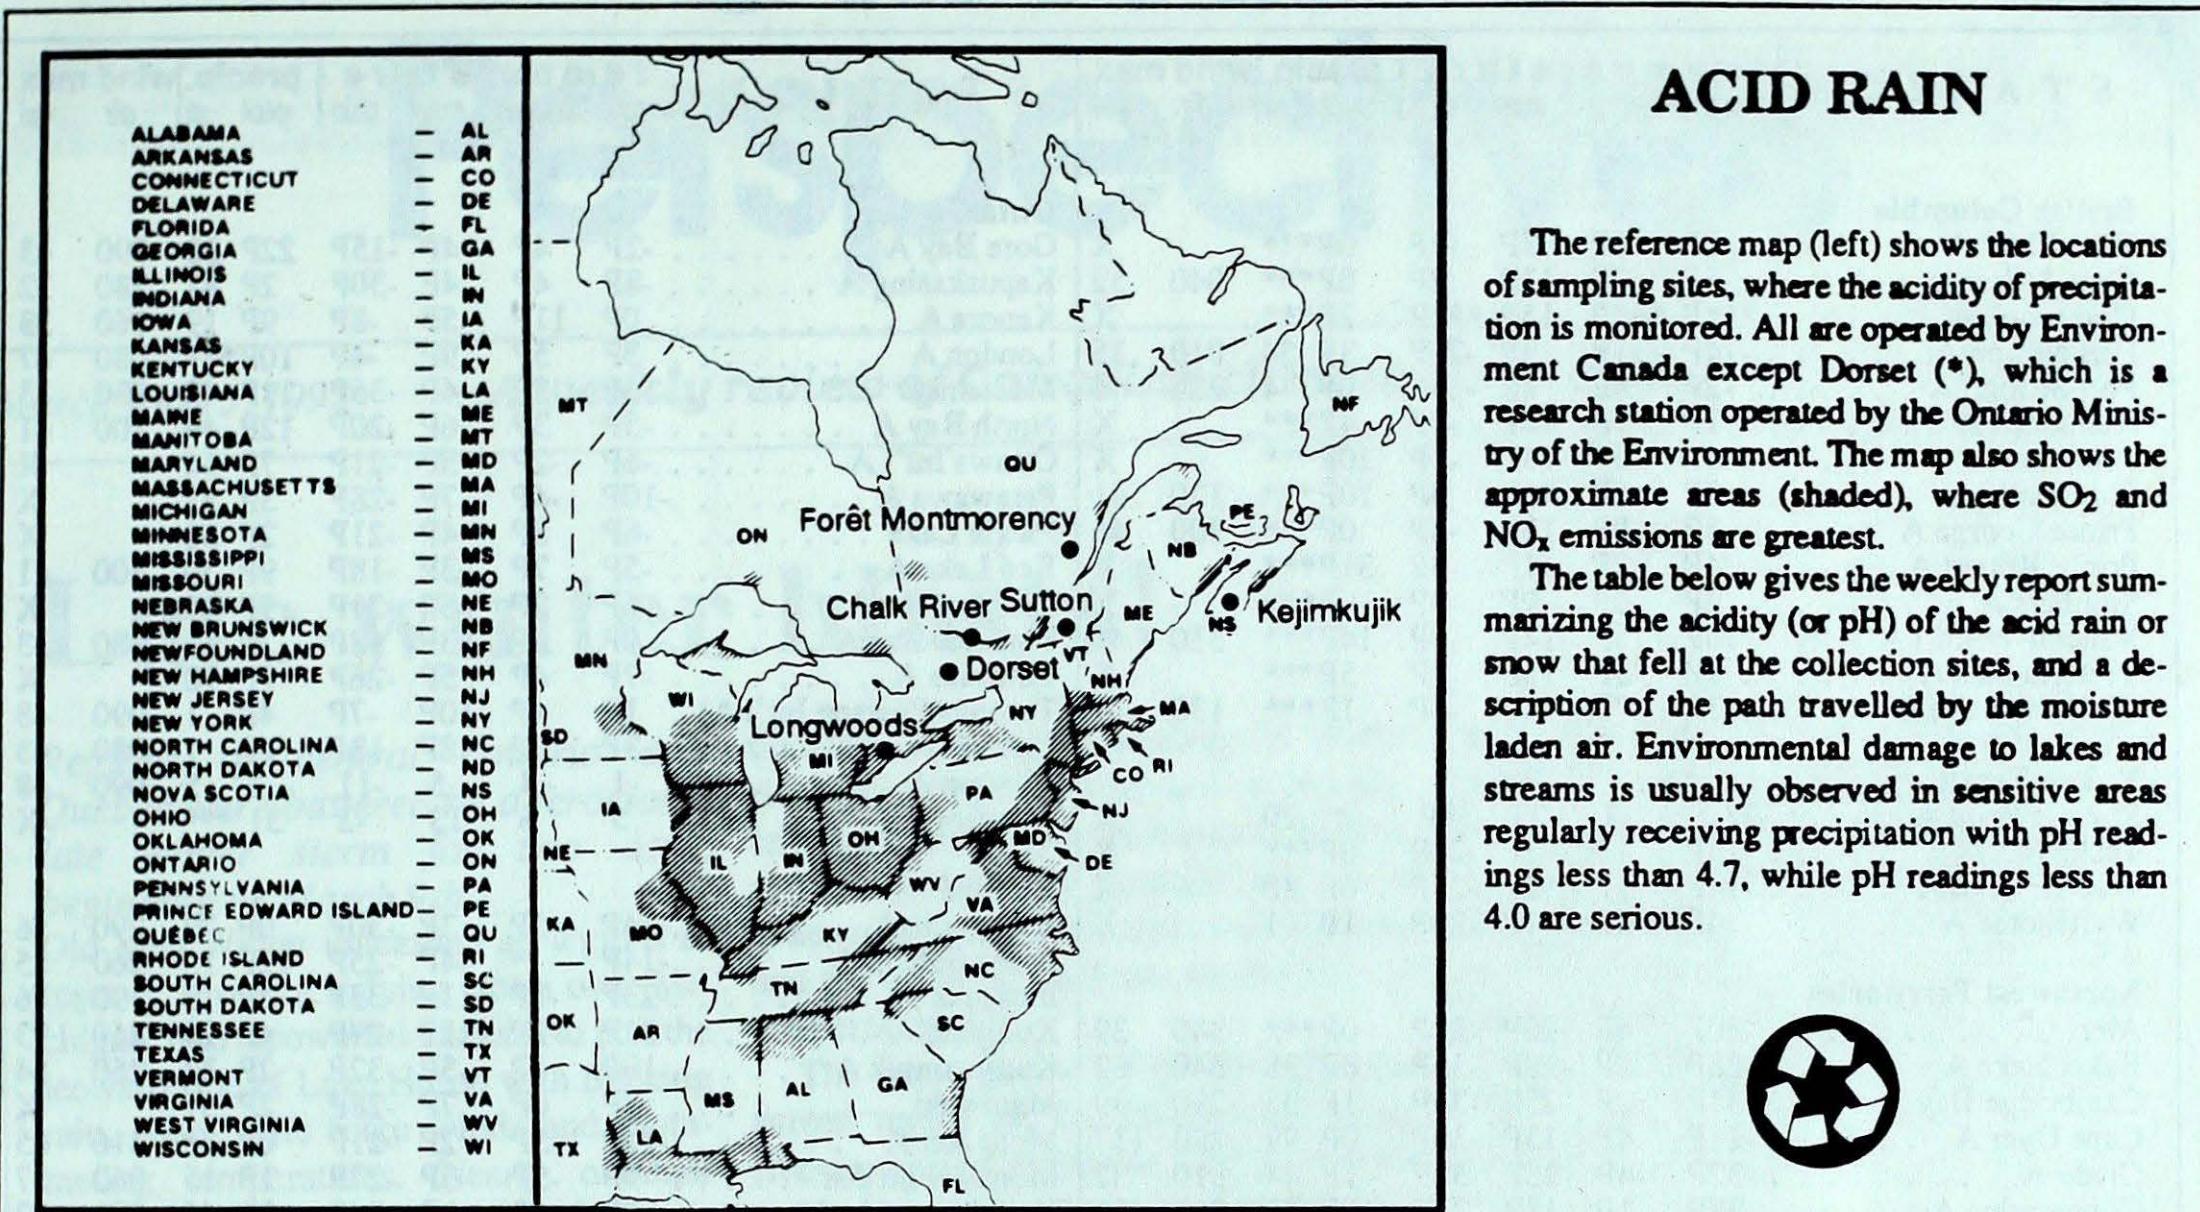

Mean geopotential height  
50-kPa level (10-decametre intervals)

Mean geopotential height anomaly  
50-kPa level (10-decametre intervals)

Tracks of low pressure centres at 12:00 U.T. each day during the period.

The reference map (left) shows the locations of sampling sites, where the acidity of precipitation is monitored. All are operated by Environment Canada except Dorset (\*), which is a research station operated by the Ontario Ministry of the Environment. The map also shows the approximate areas (shaded), where  $\text{SO}_2$  and  $\text{NO}_x$  emissions are greatest.

The table below gives the weekly report summarizing the acidity (or pH) of the acid rain or snow that fell at the collection sites, and a description of the path travelled by the moisture laden air. Environmental damage to lakes and streams is usually observed in sensitive areas regularly receiving precipitation with pH readings less than 4.7, while pH readings less than 4.0 are serious.
