

Climatic Perspectives

May 18 to 24, 1992

A weekly review of Canadian climate and water

Vol. 14 No. 21

Dry spell

An intensifying dry spell has been persisting over the south-western Prairies, where winter precipitation was significantly below normal, leaving soil moisture levels critically dry. However, abundant rain over Manitoba and eastern Saskatchewan has provided good to even excellent water supplies for farms, homes and industrial use.

In Alberta, currently over 4000 square kilometres of farmland are experiencing low or very low soil moisture levels. The cropland in some of the eastern and southern regions now runs the risk of poor seed germination and crop failure if the dry weather continues. Presently, the Brooks area is particularly dry. In Saskatchewan, Canada's largest agricultural producing province, soil moisture is rated from poor to fair in the southern and southwestern areas.

Regular precipitation in Manitoba has recharged water supplies in lakes, reservoirs and ponds and if the weather conditions for the rest of the spring and summer continue near normal, there should be no particular problem in this region.

While rangeland conditions are reported as excellent in the Peace River area cattle have grazed for most of the mild winter and the situation declines southward, such that regions, like near Lethbridge, are reporting degraded pastures and problems in obtaining water supplies from springs and shallow wells.

Ranchers may have to take measures to alleviate the stress on the parched grassland soils by reducing herds, protecting

erosion-prone soils, providing salt and emergency watering holes and seeding annuals for emergency forage.

Severe weather pounds Quebec

Two severe storms traversed parts of southern Quebec during the week. On the north side of the Ottawa River on May 17, a damaging thunder storm moved within 50 km of Hull and then into the Parc du Mont-Tremblant region.

Large hail stones peppered the ground and wind gusts up to 100 km/h caused varying degrees of damage. The intense storm induced a waterspout over the Ottawa River, and maintained its funnel form as it moved inland touching down at several spots tearing away trees, shingles, windows and knocking out electric power facilities.

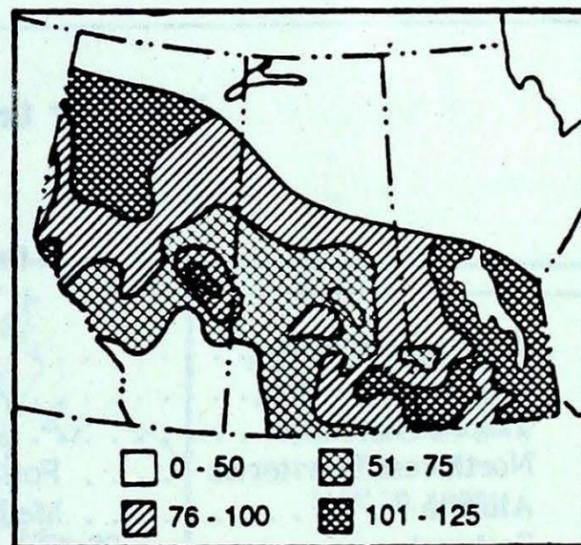

The storm force winds were also responsible for pushing an elevated passenger transporter up against the side of an aircraft at the Mirabel Airport. On the 21st another convective storm in the Mont-Joli region delivered hail and severe winds.

A look ahead ...

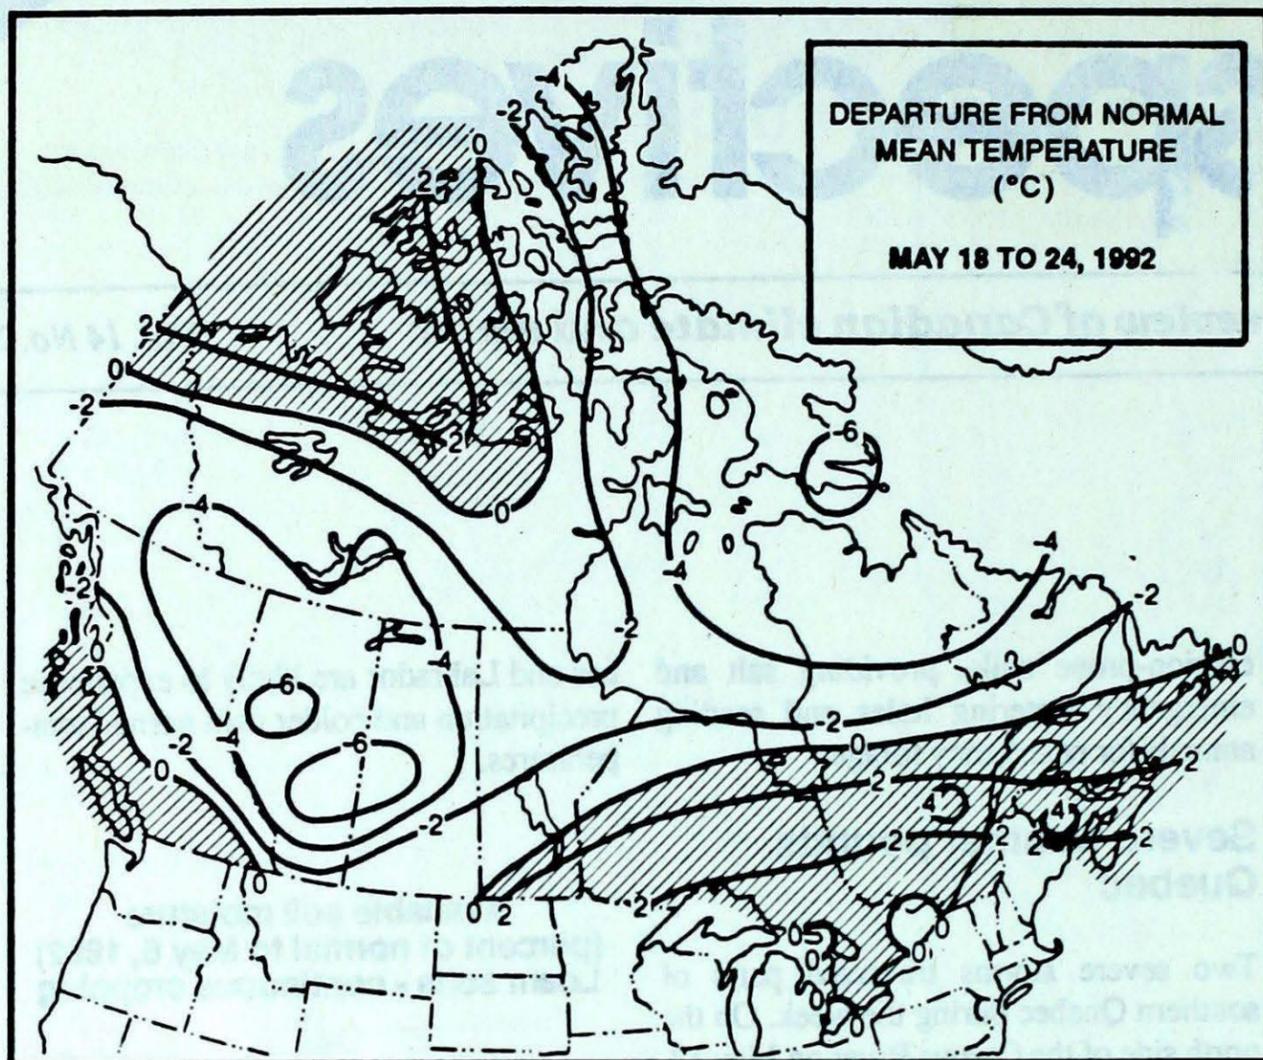

A strong ridge of high pressure over the north-western regions will combine with a centre of low pressure in the central U.S.A. to give, generally, above normal temperatures to most of the provinces for the week of June 1. At the confluence of air masses from the Arctic and the southwest, eastern Quebec, the Atlantic provin-

ces and Labrador are likely to experience precipitation and colder than normal temperatures.

Available soil moisture
(percent of normal to May 6, 1992)
Loam soils - continuous cropping

Soils in the 0-50 category, have insufficient moisture for seed germination, whereas soils in the 51-75 category generally have sufficient moisture for germination, but cannot sustain seedling growth without timely and adequate precipitation. Soils in the 76-100 and 101-125 categories have reserves sufficient to carry grain crops through most dry periods; however, the risk of excess wetness may occur in the higher category. The map pertains to medium textured soils in a level landscape. Source PFRA

Climatic Perspectives is a weekly publication (disponible aussi en français) of the Canadian Climate Centre, Atmospheric Environment Service, 4905 Dufferin St., Downsview, Ontario, Canada M3H 5T4

☎ (416) 739-4438/4436

The purpose of the publication is to make topical information available to the public concerning the Canadian Climate and its socio-economic impact.

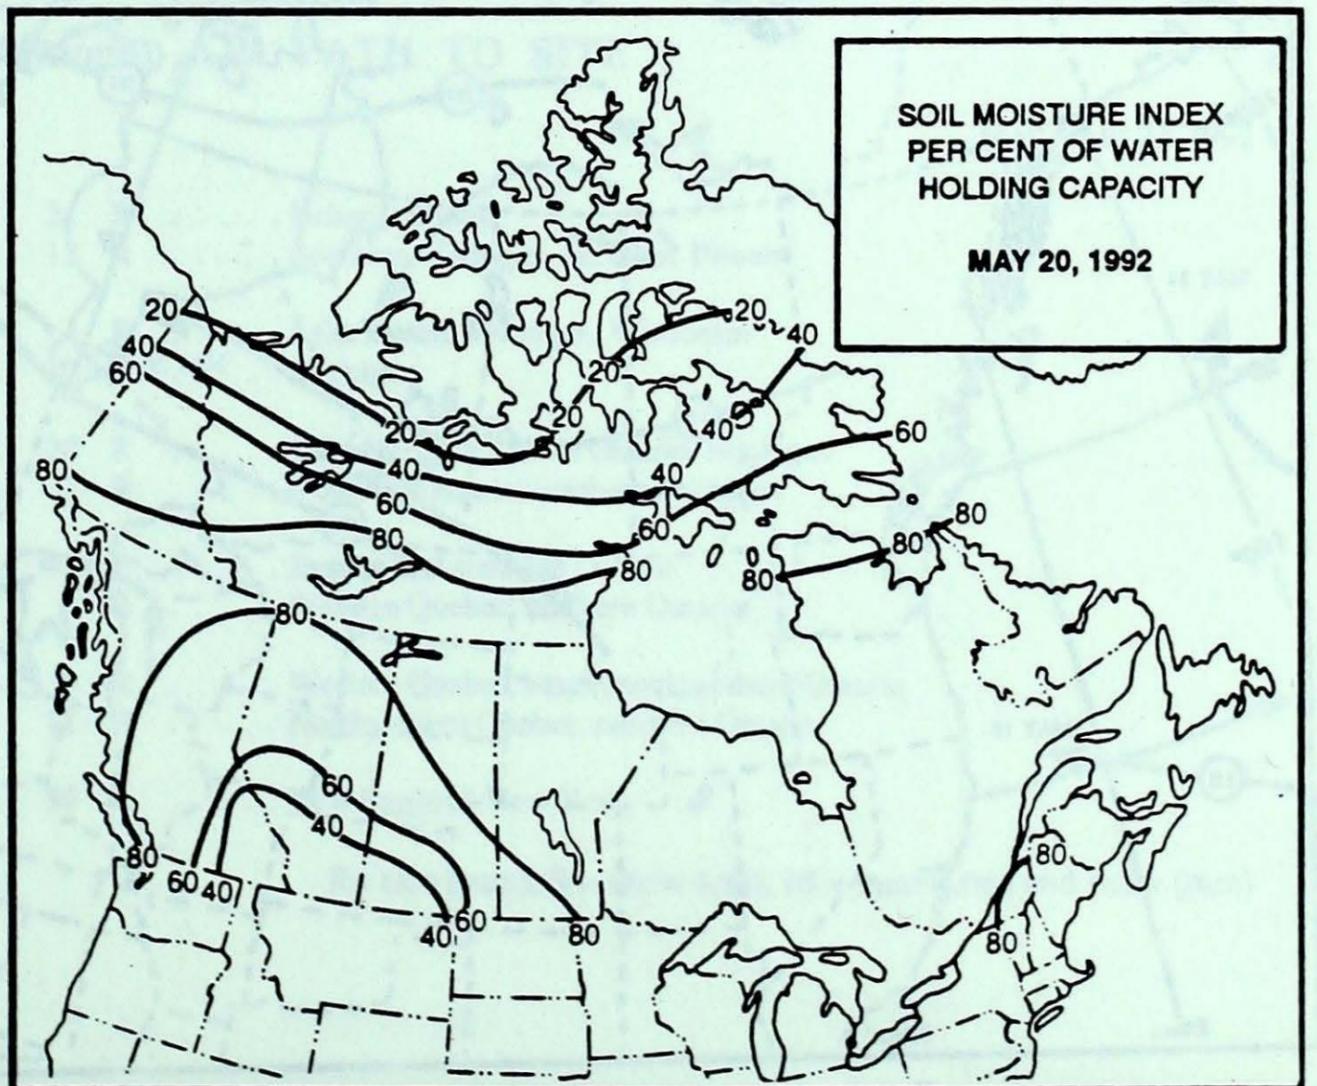

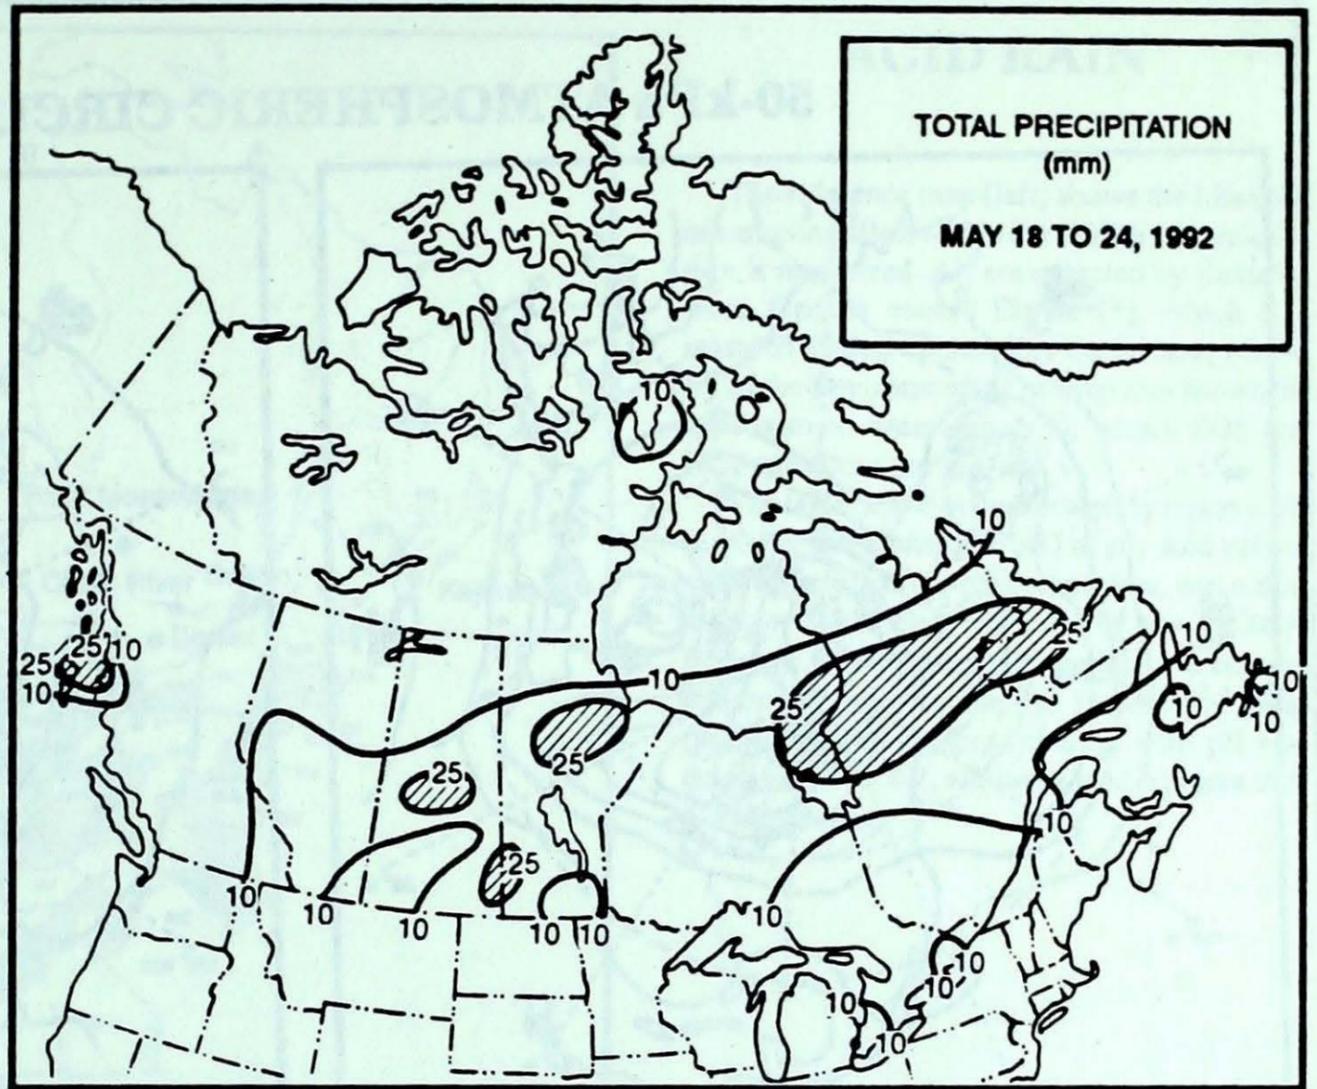

The data in this publication are based on unverified reports from approximately 225 Canadian synoptic weather stations. Information concerning climatic impacts is gathered from AES contacts with the public and from the media. Articles do not necessarily reflect the views of the Atmospheric Environment Service.

50-kPa ATMOSPHERIC CIRCULATION

Mean geopotential height
50-kPa level (10 decametre intervals)

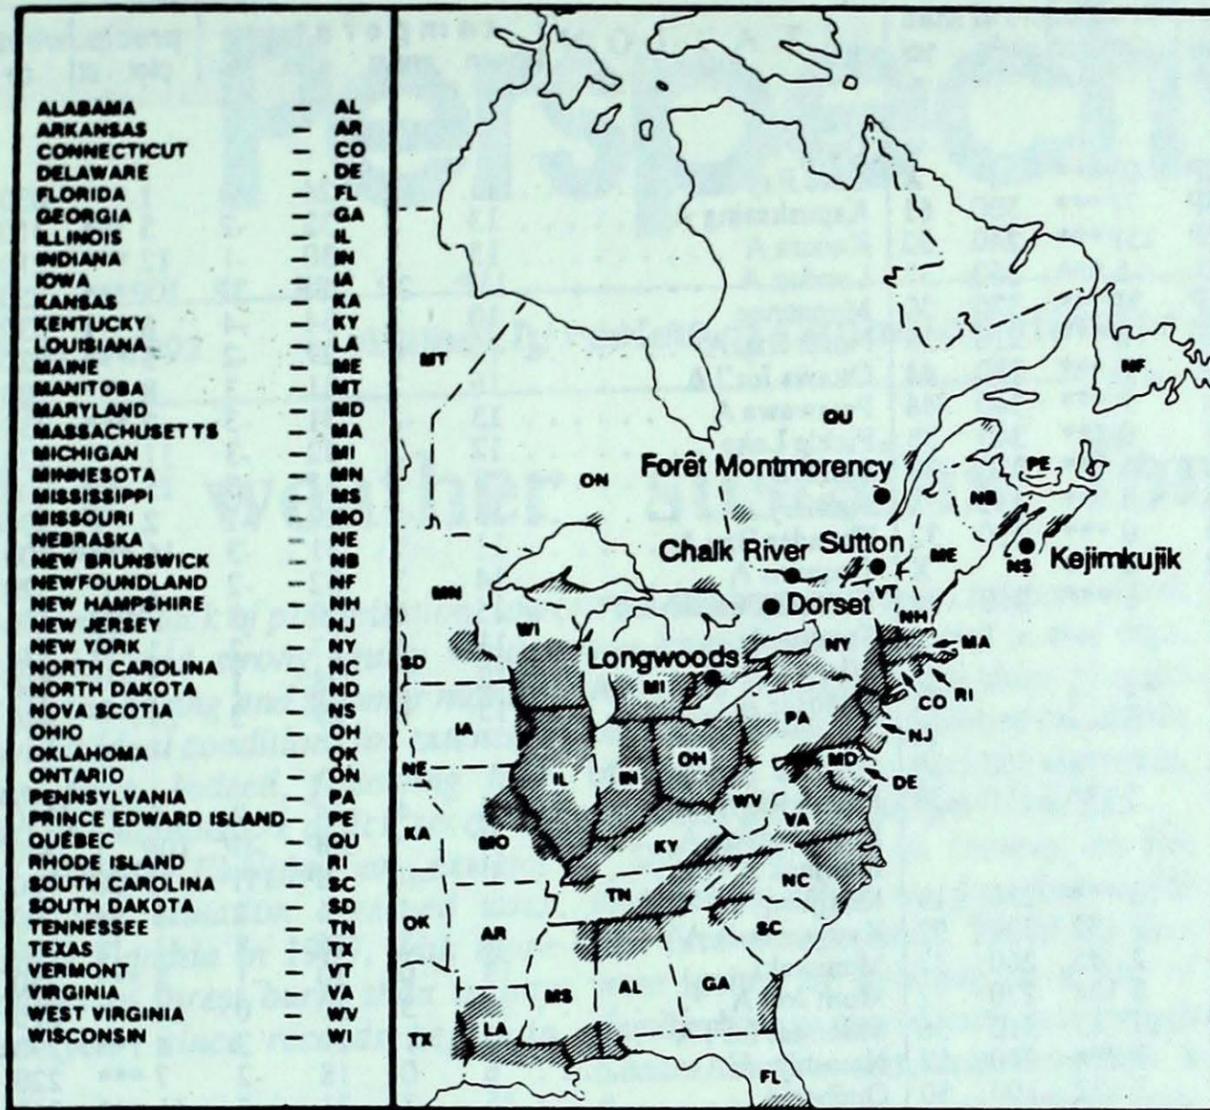

Mean geopotential height anomaly
50-kPa level (10 decametre intervals)

Tracks of low pressure centres at 12:00 U.T. each day during the period.

ACID RAIN

The reference map (left) shows the locations of sampling sites, where the acidity of precipitation is monitored. All are operated by Environment Canada except Dorset (*), which is a research station operated by the Ontario Ministry of the Environment. The map also shows the approximate areas (shaded), where SO₂ and NO_x emissions are greatest.

The table below gives the weekly report summarizing the acidity (or pH) of the acid rain or snow that fell at the collection sites, and a description of the path travelled by the moisture laden air. Environmental damage to lakes and streams is usually observed in sensitive areas regularly receiving precipitation with pH readings less than 4.7, while pH readings less than 4.0 are serious.
