Yukon and Northwest Territories

stian Olympie Contro Even though mean temperatures were below normal, a moderating trend was evident in the Yukon as daytime readings moved closer to seasonal values. Ogilvie had the distinction of being the coldest spot in Canada this week, -44° on November 16. Snowfalls were generally less than 10 cm but heavier amounts fell along the Baffin Island coast. Occasionally, blowing snow restricted visibilities on major supply routes in the Yukon. bridges on the Dempster Highway are still incomplete and are open only to restricted vehicular traffic

British Columbia

A southerly circulation allowed a mild Pacific airmass to gradually penetrate inland. With the exception of the Coast and the extreme South, mean temperatures for the week were still below normal. Day time readings climbed above freezing everywhere, except in the North. Maximum temperatures reached near 10° along the Coast. The thaw has created logging road problems in the central interior. Persistant low clouds in southern valleys disrupted local aviation traffic.

<u>Prairies</u>

A frigid Arctic airmass continued its grip over the Prairies. Mean temperatures in the North were more than 10° below normal and many new daily minimum temperature records were set in central and northern Alberta on November 15 and 16. Snowfalls were generally less than 10 cm but a disturbance crossing the provinces during the mid-week, deposited additional snowfall amounts of up to 15 cm over portions of Saskatchewan and Manitoba Only the extreme Southeast escaped the snow, where temperatures managed to climb above freezing. The combination of snow, strong winds and cold caused near blizzard conditions in the North. The Grey Cup Game in Edmonton was played in colder than expected temperatures, resulting in very slippery field conditions.

Ontario

It was a cool week with varying amounts of cloud. Daytime temperatures during the first half of
the week remained above freezing.
On November 15, temperatures in
southern Ontario reached 12°.
Heaviest amounts of precipitation,
between 15 and 30 mm, fell across
central and northern Ontario,
predominantly as rain. Cold Arctic
air flooded the province over the
weekend, triggering snow squall
activity to the lea of the Great
Lakes.

Québec

The week began on a mild note. with daytime readings in the South reaching 10°. After mid-week cold Arctic air flooded the southern half of the Province and with mainly clear skies at night, temperatures plummeted to the minus twenties, establishing many new dally minimum temperature records between November 15 and 18. Precipitation was variable and mixed. Western Quebec and the Lac Saint-Jean District were inundated with 30 to 40 cm of snow, while the lower St. Lawrence Valley received up to 35 mm of rain. There were numerous traffic accidents as a result of the first major snowfall of the season. On November 17, a 30 car pile-up occurred on the Pierre-Laporte bridge in Québec City.

Atlantic Provinces

sed

the

ton

It was a predominantly cloudy and damp week, with significant daily temperature variations. A strengthening disturbance crossed the East Coast during the early part of the week and inundated Labrador with heavy snow, while Newfoundland and the Maritimes received mostly rain. Between November 12-17, parts of the Labrador Coast received more than 100 cm of snow. In a two day period Goose Bay exceeded their normal monthly snowfall of 57 cm. Owing to strong winds in excess of 100 km/h, ferry services to Prince Edward Island were disrupted. Unusually dry conditions still persist in New Brunswick and Nova Scotia.

The Front Cover

The front cover (an image taken by the NOAA 6 weather satellite on November 13, 1984) shows the first real snowcover of the season in the Great Lakes region. Skies were virtually clear and the snow (deposited by snow squalls the previous day) can be seen along the Bruce Peninsula, the adjacent shores of Lake Huron and Georgian Bay, and also over the thumb of Michigan. Snow squalls in these areas are common and result from the interaction of arctic air passing over the warmer waters of Lake Huron and Georgian Bay. As the picture reveals, such squalls are a very localized phenomenon.

SNOW DEPTH ON THE GROUND

TEMPERATURE ANOMALY FORECAST

Temperature Anomaly Forecast

The temperature anomaly forecast, for each of the 70 Canadian stations, is prepared by searching historical weather maps to find cases similar to the present one. The principle used is that a prediction for the next 15 days may be based on what is known to have actually happened during 15-day periods. After the five best cases are sethe surface temperature lected, anomalies are calculated. This results in five separate forecasts, which are averaged to provide the forecast depicted.

TEMPERATURE OF THE GREAT LAKES, 1984 (°C)

During 1983, the water surface temperatures of the Great Lakes were the warmest since records began in 1965. Averaged over the year, Lake Erie was 1.5°C

higher than usual, Lake Ontario 1.8°C, Lake Huron 1.7°C, Georgian Bay 1.4°C, and Lake Superior 2.0°C warmer than normal. During 1984, the temperature trend from January to August (the latest data available) on all the Lakes was much closer to normal although Lake Superior has continued on the warm side.
