## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

#### Abstract

Landings of Haddock in Northwest Atlantic Fisheries Organization Divisions (NAFO) 4X5Y in the 2014/15 and 2015/16 fishing years were 2,825 tonnes (t) and 2,926 t, respectively, relative to a quota of 5,100 t. The Fisheries and Oceans Canada (DFO) Summer Research Vessel (RV) survey biomass index in 2015 and 2016 was 69,800 t and 62,700 t, respectively; both years are above the short ( 5 year: 48,193 t) and long-term (since 1970: 55,470 t) averages. For both the commercial fishery and the DFO Summer RV survey, values for the mean weight-at-age and length-at-age show a decline from the early 1990s to the mid-2000s and then a levelling off or a modest increase, followed by the lowest weight-at-age for many ages occurring in 2015. The beginning of year spawning stock biomass for 2016 was estimated to be 33,770 t using a Virtual Population Analysis (VPA), which is above the established biomass limit reference point ( $\mathrm{B}_{\mathrm{lim}}$ ) of $19,700 t$ and the long-term average of $32,258 \mathrm{t}$. The preliminary estimates for the 2013 year class at Age 1 remain extraordinarily high for this stock at 264 million recruits, and the estimate for the 2014 year class (Age 1 in 2015) is 74 million, above the long-term geometric mean for Age 1 of 20 million recruits. The estimated fishing mortality (F) for ages 6 to 10 in 2015 was 0.05 for 4X5Y Haddock, therefore below the fishing mortality reference point ( $F_{\text {ref }}$ ) in both the Healthy Zone ( $\mathrm{F}_{\text {ref }}=0.25$ ) and Cautious Zone ( $\mathrm{F}=0.15$ ). In the absence of an Upper Stock Reference point, it cannot be distinguished whether the stock is in the Cautious or Healthy Zone; therefore, deterministic and stochastic projections were conducted using both $F_{\text {ref }}=0.25$ and $F=0.15$ scenarios. Under the various harvest scenarios examined, the spawning stock biomass is projected to increase to around $100,000 \mathrm{t}$, double the previous peak observed from the 1985 to 2015 time series. The 2013 year class at Age 4 is expected to contribute $61 \%$ of the 1+ population biomass in 2017 and 59\% in 2018 (Age 5). Notably, the 2013 year class appears to be much stronger than anything previously observed, but there is uncertainty around this estimate given the retrospective pattern in the model, the small number of observations in both the survey and fishery, and the apparent mismatch between survey abundance estimates and the VPA in recent years. The future performance of the 2013 and 2014 year classes will impact the stock dynamics.

## INTRODUCTION

Haddock (Melanogrammus aeglefinus) are found on both sides of the North Atlantic; they occur in the northwestern Atlantic from southwest Greenland to Cape Hatteras. A major stock exists on the western Scotian Shelf and in the Bay of Fundy (Northwest Atlantic Fisheries Organization (NAFO) Divisions 4X5Y) (Figure 1). Growth rates of Haddock in the Bay of Fundy (4Xqrs5Y) are higher than those of Haddock on the western Scotian Shelf (4Xmnop) (Hurley et al. 1998) so that separate Age Length Keys (ALKs) have been used in the past for calculating the fishery catch-at-age (CAA) and survey indices of abundance. Major spawning grounds are found on Browns Bank, and peak spawning occurs from April to May (Page and Frank 1989), although it can occur as early as February if conditions are favourable (Head et al. 2005). A seasonal spawning closure was implemented on Browns Bank in 1970, which is closed from February $1^{\text {st }}$ to June $15^{\text {th }}$ (Halliday 1988).

Haddock in NAFO Divisions 4X5Y (herein after referred to as 4X5Y Haddock) are harvested as part of a mixed, multi-species fishery that includes Atlantic Cod, Halibut, redfish, Pollock, White Hake, and flounders. The Haddock fishery is limited by the incidental catch of Atlantic Cod, which has strict bycatch limits. The mandatory use of a 130 mm square mesh cod end for bottom trawl was implemented in 1991 to allow for escapement of smaller fish; however, Haddock are also captured as bycatch in the redfish fishery, which uses smaller 100-112 mm diamond mesh cod ends.

The last assessment of the 4X5Y Haddock stock was conducted using data up to 2011 (Showell et al. 2013). A continuing strong retrospective pattern in the Sequential Population Analysis (SPA) model and poor model fit to survey indices led to a framework review. The recent framework review of 4X5Y Haddock occurred in two parts. The first part focused on commercial fishery and survey data inputs, which were evaluated during a meeting conducted at the Bedford Institute of Oceanography in Dartmouth, NS, on October 22, 2014, and documented in Stone and Hansen (2015). The second part took place at the Biological Station in St. Andrews, NB, from April 26-27, 2016, and focused on the model(s) used to determine stock status, reference points, risk analysis and the inter-framework assessment strategy (Wang et al. 2017).
The objectives of this regional peer review process were to:

- Evaluate biological and fishery information on 4X5Y Haddock stock status and characterize the uncertainty of the results. Specifically, provide information on distribution, biomass estimates, length and age composition, condition, highlighting trends over the long-term (length of assessment) and most recent period (5 years).
- Evaluate the current status of the stock relative to the adopted reference points.
- Evaluate the consequences of different harvest levels during the 2017/18 fishery on stock abundance and fishing mortality. Where possible, provide the following information:
o For a range of total catch values, estimate the risk that fishing mortality rate (F) would exceed the reference level for when the stock is in the Healthy Zone ( $\mathrm{F}_{\text {ref }}=0.25$ ) and the recommended $F$ for when the stock is in the Cautious Zone ( $F=0.15$ ) in 2017 and 2018. Include a table showing the catches corresponding to low (25\%), neutral (50\%), and high (75\%) probability that F would exceed $\mathrm{F}=0.25$ and $\mathrm{F}=0.15$.
o For a range of total catch values in 2017 and 2018, estimate the probability that spawning biomass at the beginning of year 2018 and 2019 would remain stable or not increase by $10 \%$ from the previous year's level.
o Sensitivity analysis on the estimate of probability that the fishing mortality rate would exceed $F=0.25$ and $F=0.15$ in 2017/18 and the expected spawning biomass change under constant Total Allowable Catch (TAC).
This assessment includes the DFO Summer Research Vessel (RV) survey biomass index data up to 2016, as well as commercial landings data up to 2015. The stock is modeled using a Virtual Population Analysis (VPA) model and data framework as in Wang et al. (2017); the population model, projection, and risk analyses include 1985-2015 data.

## THE FISHERY

## COMMERCIAL LANDINGS

Reported annual landings of 4X5Y Haddock averaged 18,500 t during the 1970s and 19,800 t during the 1980s, with peaks occurring in the late 1960s and early 1980s (Table 1, Figure 2). Noteworthy is that from 1982-1984 the TAC peaked at 32,000 t but was quickly reduced to $4,600 \mathrm{t}$ by 1989. In 1991 and 1992, there was no TAC for Haddock under a Management Plan that called for a bycatch fishery only, although landings exceeded $9,000 \mathrm{t}$ during these years (Hurley et al. 2009). The TAC of $8,100 \mathrm{t}$ established for the 12 month fishery in 1999 was extended to 9,800 t for the 15 -month period ending March 31, 2000. The fishing year since then has been April $1^{\text {st }}$ to March $31^{\text {st }}$. Annual landings dropped substantially in the 1990 s and 2000s, averaging $6,681 \mathrm{t}$ and 4,260 t , respectively. Since 2010, landings have been below $5,000 \mathrm{t}$ and in 2014 and 2015 they were $2,718 \mathrm{t}$ and $2,747 \mathrm{t}$, the lowest in the 40 year time series. The Fishing Year (FY) TAC (FY, April $1^{\text {st }}$ - March $31^{\text {st }}$ ) was $7,000 \mathrm{t}$ from 2006-2009, but it was subsequently reduced to $6,000 \mathrm{t}$ for $\mathrm{FYs} 2010 / 2011$ and 2011/2012 and to $5,100 \mathrm{t}$ for FYs 2012/2013 through 2015/2016 (Table 1). Fishing year landings for 2014/2015 and 2015/2016 were $2,825 \mathrm{t}$ and $2,926 \mathrm{t}$, respectively, well below the TAC.
Since the mid-1970s, the small mobile gear component (bottom trawl, Tonnage Class (TC) 1-3) has accounted for most of the total landings, with the exception of the early 1990s when the percentage taken by fixed gear (longline) was greater (Figure 3, Table 2). The percentage of landings from longline has steadily declined since 1994, whereas the small mobile gear share has increased. Over the past 10 years, small otter trawlers (TC 1-3) have taken an average of about $80 \%$ of the catch and longline vessels about $20 \%$. There has been a declining trend in longline catches since 2011, with the 2015 catch representing only $4 \%$ of total landings (compared to $96 \%$ for mobile gear). Large otter trawlers (TC 4+) contributed $30-40 \%$ of total landings in the 1970s, but there are few left in the fishery at present (their contribution is currently $<1 \%$ ). The contribution by the handline and gillnet sectors has also declined to very low levels (< 1\%) since the late 1990s.
Since 2010, most landings have occurred during the first quarter (42\%), followed by the third (25\%), fourth (19\%) and second (14\%) quarters (Table 3). The change to an April-March fishing year in 2000 has led to an increase in the proportion of fish landed during January to March, a seasonal change that has helped to reduce the bycatch of cod (Hurley et al. 2009). This is also when the Georges Bank fishery for Haddock is closed (i.e. mid-February to May $31^{\text {st }}$ ), so there is likely a shift to fishing the 4X5Y stock at this time of year. Over the past decade, about 75\% of total landings have been taken from Scotian Shelf statistical unit areas 4Xn and 4Xp (Figure 4). While the increase in 4 Xn is largely a result of the winter (January-March) fishery, the increase in $4 X p$ reflects directing for larger Haddock in the deeper waters of the Fundian Channel where the bycatch of cod also tends to be lower (Hurley et al. 2009). Haddock landings in 4Xp remained high, contributing 45\% of the total landings in 2015 and an average of $40 \%$ over the past five years (Figure 4).

Most of the 4X5Y Haddock fishery catch is currently taken on the Scotian Shelf (4Xmnop) by the mobile gear sector, with the majority of the remainder taken in the Bay of Fundy (4Xqrs5Y) by mobile gear (Table 4, Figure 5 and 6). Fixed gear catches from both the Bay of Fundy and Scotian Shelf regions remain low, contributing only 4\% and <1\%, respectively in 2015 (Table 4; Figure 6).

## FISHERY CATCH-AT-AGE AND LENGTH/WEIGHT-AT-AGE

The 4X5Y Haddock fishery catch-at-age (CAA), weight-at-age (WAA), and length-at-age (LAA) was updated for 2015 (see Stone and Hansen 2015 for revision history). For CAA calculations, the length frequencies obtained by port samplers were grouped by Gear (Mobile, Fixed), Season (QTR or Half Year) and Area (Bay of Fundy: 4Xqrs5Y; Scotian Shelf: 4Xmnop). Age length keys (ALKs) were grouped by Area and Season (Qtr or Half Year). Annual length-weight relationships (a's and b's) for Haddock from the DFO Summer Research Survey were calculated separately for Bay of Fundy Strata (482-495) and Scotian Shelf Strata (470-481) and applied to matching sample areas for CAA determinations.

Ages were assigned by a single ager. As a routine check, the ager initially read the 4X5Y Haddock reference collection. A pair-wise comparison of ages showed high precision, 92.5\% agreement in 2015 and little bias with an overall coefficient of variation of 1.42\% (Appendix). These results were considered acceptable.

Catch-at-age (CAA) calculations for 2011, 2012 and 2013 included a separate category for Haddock catches from the 4X redfish fishery which uses a smaller cod end mesh size (i.e. 100112 mm diamond mesh) and has a tendency to retain more small fish (i.e. ages 2-3). Haddock catches from the 4 X redfish fishery increased from < 1\% of total landings in the early 1990s to $8 \%$ by 2002 , declined to $<2 \%$ in 2003-2004, then increased steadily reaching $15 \%$ in 2012 and $13 \%$ in 2013 before dropping off to $3 \%$ in 2015 (Figure 7). For 2011-2015, small mesh gear landings of Haddock were $325 \mathrm{t}, 623 \mathrm{t}, 460 \mathrm{t}, 128 \mathrm{t}$, and 82 t , respectively. There were too few port samples available to size the small mesh catches in CAA calculations with the exception of 2011-2013.
The 4X5Y Haddock fishery CAA data for assessment modelling includes ages 1-14 for 19852015 (Table 5, Figure 8). This series shows the presence of some recent strong year classes (i.e. 2003, 2010, and the incoming 2013) and a reduction in the catches of Age 2 fish beginning in the early 1990s. The latter coincides with the mandatory use of 130 mm square mesh in 1991, but also there has been a decline in WAA and LAA during this period that has reduced the partial recruitment/selectivity of this age group (Table 6; Figure 9 and 10). In the 2015 fishery, the 2010 year class at Age 5 was predominant and represented $32 \%$ of the CAA followed by the 2011 year class at $27 \%$. The 2003 year class, which made a significant contribution to the fishery back to 2006, represented only $0.5 \%$ of the 2015 fishery catch at Age 12. Noteworthy is that older fish (Age 10+) continue to appear in the time series up until 2015.

There have been changes in the catch at size by gear type (mobile vs. fixed) and area (Bay of Fundy vs. Scotian Shelf) over the 30 year time period (1985-2014), which could contribute to changes in selectivity and partial recruitment to the fishery (Figure 11). Not only are Haddock captured in the recent period (2010-2015) considerably smaller than they were in the past, but the contribution from the fixed gear sector has diminished. Fixed gear has generally captured larger fish than mobile gear.
Fishery mean weights-at-age (WAA, kg ) and lengths-at-age (LAA, cm) for 2015 were calculated from the CAA application (Table 6, Figure 9 and 10). The weighting of WAA is done internally in the CAA workspace. Separate age length keys were used for Scotian Shelf and Bay of Fundy
samples to generate numbers-at-age that were then used for weighting the calculations of the overall fishery WAA. Both series indicated a declining trend in WAA and LAA from the early 1990s to mid-2000s and then either showed a modest increase or a leveling off in the recent period, followed by a decrease in 2015. While it is not clear what caused the declining trend over this time period, the effect on stock productivity is significant and has been discussed in previous assessments (Hurley et al. 2009, Mohn et al. 2010). In 2015, the mean weight-at-age for ages $1,2,3,4,5,8$, and 9 are the lowest in the time series (Table 6).

## DFO SUMMER RESEARCH VESSEL SURVEY UPDATE

## CATCH DISTRIBUTION, INDICIES OF ABUNDANCE, LENGTH/WEIGHT-AT-AGE

Fisheries and Oceans Canada (DFO) has conducted a stratified random bottom trawl survey of the Scotian Shelf and Bay of Fundy every summer since 1970. Over the 47 year DFO Summer RV survey time series (1970-2016), the main areas of Haddock abundance have been on Browns Bank, Baccaro Bank and the outer Bay of Fundy area (Figure 12).

Due to differences in growth rates (Hurley et al. 1998), the total biomass index is calculated separately for the Bay of Fundy (Strata 482-495) and western Scotian Shelf (Strata 470-481) for 1970-2016 (Figure 13). While both indices show high variability over the time series, the general pattern is one of decreasing biomass from the mid-1980s to mid-1990s, followed by a period of increasing biomass through the late 1990s to the early-2000s, then lower biomass from 2004-2013, and then an increase (Table 7, Figure 14). 2015 is the first year that the total biomass index has been above the long term mean since 2011 for the western Scotian Shelf and since 2003 for the Bay of Fundy. In 2015, the total biomass estimate for the Bay of Fundy was $32,200 \mathrm{t}$ and for the Scotian Shelf it was $37,600 \mathrm{t}$, the total biomass index in 2015 for both areas combined was $69,800 \mathrm{t}$. In 2016, the total biomass estimate for the Bay of Fundy was $38,000 \mathrm{t}$ and for the Scotian Shelf it was $24,700 \mathrm{t}$. The total biomass index in 2016 for both areas combined was $62,700 \mathrm{t}$, remaining above the time series average of $55,400 \mathrm{t}$.
The age-specific indices of abundance (total numbers at age) for 1970-2015 were calculated separately for Bay of Fundy Strata (482-495) and western Scotian Shelf Strata (470-481) and then combined to generate the indices of abundance for the entire 4 X 5 Y management area (Strata 470-495) (Table 8). Since the early portion of the series was not re-aged, only data from 1985-2015 were used as the tuning index in VPA modelling (Figure 15). During the late 1980s, there was a period of diminished numbers at age for all ages that persisted until the early 1990s. The abundance at age increased from 1995-2002, especially for ages 1-5, and was followed by an overall improvement in age structure, with increased abundance of ages $6+$ up to about 2011. The 2003, 2006, and 2010 year classes all appear to have been moderately strong, with indications that the 2013 year class (Age 2 in 2015) is the strongest in the time series. In 2015, the 2013 year class (Age 2) made up 54\% the survey CAA, the 2014 year class (Age 1) represented 17\%, followed by the 2012 year class (Age 3) represented 13\%.
The DFO Summer RV survey mean WAA (kg) and mean LAA (cm) for 4X5Y Haddock was calculated separately for Bay of Fundy and western Scotian Shelf strata, then combined after weighting using total abundance at age for each area (Tables 9 and 10). The revised survey WAA time series for 1985-2015 is used for calculations of beginning of year biomass after applying the Rivard back-calculation method (Rivard 1980). Similar to the trends observed for the commercial fishery, the DFO Summer RV survey values for mean WAA and LAA show a decline from the early 1990s to the mid-2000s then level off or show a modest increase followed by the lowest WAA for many ages occurring in 2015 (Figure 16 and 17, Table 9 and 10). A comparison of 4X5Y Haddock mean LAA for ages 3,5,7 and 9 from the commercial fishery and
the DFO Summer RV survey indicates a higher mean length at Age 3 in the fishery compared to the survey, with diminishing differences as age increases (Figure 18).
An analysis of condition factor, using Fulton's K (weight/length ${ }^{3}$ ) showed that condition declined in Haddock (length range: $28-55 \mathrm{~cm}$ ) from the early 1990s to mid-2000s for both areas, then showed a modest increase to 2009 before decreasing again in recent years (Figure 19). Fulton's K has generally been at or below the long term average (1970-2016) since 1993 for both areas. The overall pattern is consistent with declining trends in WAA and LAA and is similar to what has been observed for other species on the Scotian Shelf (i.e., Silver Hake, Pollock).

## ESTIMATE OF STOCK PARAMETERS AND RESULTS

Prior to running the framework population model, a Virtual Population Analysis (VPA) model with random walk in natural mortality (M) was completed, including 1985-2015 data (see Wang et al. 2017 for model details). Estimated M for the 3 younger age groups 1-3, 4-6, and 7-9 continue to be relatively stable and stayed around 0.2 , and M for older ages $10+$ were greater and estimated as about 0.27 in the early years (1985-1990), then increased since 2000 and reached a higher level of 0.8 in most recent years (Figure 20). Natural mortality (M) for the 10+ was estimated as 0.72 in 2015 and confirms that M remains high for older ages.

The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating the VPA with the trends in abundance from the DFO Summer RV survey. For 4X5Y Haddock, the model data inputs were fishery CAA for ages 1-11+ (1985-2015) and DFO Summer RV Survey swept area abundance indices for ages 1-10 (1985-2015). Zero observations for abundance indices were treated as missing data. Fishing mortality on the plus group (F11+) was set up using the Fratio method in ADAPT. Mortality was fixed at 0.2 for all the ages and years except for the ages 10$11+$ after 2000. Mortality was fixed at $0.3,0.6$, and 0.9 for ages $10-11+$ for three time blocks (2000-2004, 2005-2009 and 2010-2015) as recommended during the framework. The abundance at Age 1 for 2016 was assigned as the most recent 10 years of geometric mean of recruitment at Age 1 (excluding the exceptional strong 2013 year class). Other model parameters included survey catchability at age for ages 1-10 and terminal year population abundance at age for ages 2-11+. All the parameters were estimated by minimization of the discrepancy between observed and predicted values of the abundance indices at age, which were assumed to be log-normally distributed. Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Rivard and Gavaris 2003).
The model residuals (Figure 21) suggest that some of the stronger cohorts at younger ages were underestimated by the model. The Coefficient of Variation (CV) for numbers at Age 2 for the terminal year (2016) was 0.6 (Table 11). The youngest age is expected to have the highest CV due to the limited data available for that year class. The CV for the numbers at Age 3, the 2013 year class (yc), remains high 0.4 (Table 11). The CV for numbers at age for ages 4-11+ range from 0.19 to 0.35 (Table 11). The retrospective analysis still shows some minor retrospective patterns. For the most recent years, the model tends to overestimate the biomass and underestimate $F$ when each year of data is peeled off (Figure 22). Survey catchability starts at 0.5 for Age 1 increases to around 1.0 at the fully recruited Age 4 with a relatively flat topped selectivity for the older ages (Table 11, Figure 23).
The calculated fishing mortality ( $F$ ), the population number weighted average over ages $6-10$, is shown in Figure 22 and Table 12. The model results show high fishing mortality early in the time series until about 1998, after which fishing mortality remained low. Fishing mortality (F) was estimated as 0.05 in 2015. Spawning Stock Biomass (Age 4+) decreased from 42,000 t in 1985
to $20,000 \mathrm{t}$ in 1990, and started to increase in 1996 due to the contribution of the strong cohorts of 1993, 1994, 1998, 1999, and 2000; the estimated spawning stock biomass at the beginning of 2016 was 33,770 t (Figure 22 and Table 13). Preliminary estimates for the 2013 year class at Age 1 remain extraordinarily high for this stock at 264 million recruits, but as expected, it is lower than the original estimate of 317 million from the framework. The estimate for the 2014 year class (Age 1 in 2015) is 74 million, which is above the long term average for Age 1 of 31 million recruits.

## STATE OF THE RESOURCE RELATIVE TO THE ADOPTED REFERENCE POINTS

Despite the uncertainties with the estimate of $\mathrm{F}_{\text {ref }}$ for 4X5Y Haddock, it was agreed at the framework meeting that $F_{\text {ref }}$ when the stock is in the Healthy Zone would be 0.25 , an estimated $F_{\text {msy }}$ value from the Ricker model with a $25 \%$ probability exceeding $F_{\text {loss }}$ based on LOESS analysis. $F_{\text {median }}=0.15$ from the replacement line analysis was suggested as a more appropriate target for 4X5Y Haddock in the Cautious Zone. The estimated fishing mortality in 2015 from this assessment was 0.05 for 4 X 5 Y Haddock (Figure 22, Table 12), therefore below the $\mathrm{F}_{\text {ref }}$ in both Healthy Zone and Cautious Zone scenarios.

At the Framework meeting, it was agreed that $\mathrm{B}_{\text {recover }}(19,700 \mathrm{t})$ would be the lower biomass reference point ( $\mathrm{B}_{\mathrm{lim}}$ ). The estimate of the 4+ biomass in 2016 is $33,770 \mathrm{t}$ for 4 X 5 Y Haddock, above the established $\mathrm{B}_{\text {lim }}$ reference point (Table 13 and Figure 24).

## PROJECTION AND RISK ANALYSIS

The 4X5Y Haddock age-structured fishery and survey information were updated to 2015. Beginning of terminal year (2016) population abundance was estimated from the ADAPT VPA model formulation with the value for natural mortality fixed at 0.2 , except during the three time blocks of 2000-2004, 2005-2009 and 2010-2015 when M was equal to $0.3,0.6$, and 0.9 respectively for ages 10-11+. Due to many of the weights at age in 2015 being the lowest in the time series (fishery and survey, 1985-2015) the 5-year average WAA was higher than the 2015 WAA (Figure 25). Since the 5 -year average would likely to lead to an overestimate of the population a more precautionary WAA, the most recent 2015 WAA, was used for both the average fishery WAA and the beginning of year population WAA. All other projection input parameters, including the 5-year average of fishery PR and the most recent 10 years of geometric mean of recruitment at Age 1 (excluding the exceptionally strong 2013 year class), remained consistent with the framework formulation (Table 14).
In the absence of an Upper Stock Reference to determine whether the stock is in the Cautious or Healthy Zone, projections were conducted using both scenarios with $F_{\text {ref }}=0.25$ and $F=0.15$. A deterministic projection was conducted with a catch of $5,100 t$ in 2016 under fishing at $F_{\text {ref }}=0.25$ in the Healthy Zone scenario for 2017 and 2018 (Table 15), and a second deterministic projection was conducted under fishing at $\mathrm{F}=0.15$ in the Cautious Zone scenario for 2017 and 2018 (Table 16). In both scenarios, Spawning Stock Biomass (SSB) estimates for 2017-2019 remained above the time series average and $\mathrm{B}_{\text {lim }}$ (Figure 24).

The 2013 year class was estimated to contribute $61 \%$ of the population biomass projected for 2017 and 59\% in 2018 (Table 15). Due to the uncertainties around the model estimate of the 2013 year class and the significant impact of that estimate on projections, sensitivity deterministic projections were conducted assuming the 2013 year class recruitment was equal to the largest recruitment in the time series prior to 2013 ( 54 million). Given that the 2013 year class appears to be much stronger than anything previously observed and that the 54 million falls outside of the $90 \%$ confidence interval for the estimate of the 2013 year class (104 million
to 348 million in numbers), this is a conservative approach to assessing this uncertainty. The deterministic results for this sensitivity projection are shown in Table 17 and 18. In both scenarios ( $\mathrm{F}_{\mathrm{ref}}=0.25$ and $\mathrm{F}=0.15$ ), the sensitivity projection SSB estimates for 2017-2019 remained above the time series average and $\mathrm{B}_{\text {lim }}$ (Figure 24).

Uncertainty about current biomass generates uncertainty in forecast results, which was expressed here as the risk of exceeding the proposed limit $\mathrm{F}_{\text {ref }}=0.25$ and the recommended F while the stock is in the Cautious Zone, $\mathrm{F}=0.15$, in 2017 and 2018, and the probability of adult biomass changes relative to 2018 and 2019. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are dependent on the data and model assumptions and do not include uncertainty due to variations in weight-at-age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough, and/or retrospective bias. These projections assume that the current productivity conditions will persist over the projection period.

The stochastic projections were completed to provide the risk of F in 2017 exceeding $\mathrm{F}_{\text {ref }}=0.25$ under a range of catch values, risk of $F$ exceeding $F=0.15$ under a range of catch values, probability that the 2018 biomass would remain stable, and probability that biomass would not increase by 10\% when compared to 2017 (Table 19 and Figure 26). Secondly, stochastic projections were completed to provide the risk of $F$ in 2018 exceeding $F_{\text {ref }}=0.25$, risk of $F$ in 2018 exceeding $\mathrm{F}=0.15$ for a range of catch values, probability that the 2019 biomass would remain stable, and the probability that the 2019 biomass would not increase by $10 \%$ compared to 2018 under an $\mathrm{F}_{\text {ref }}=0.25$ (Figure 27) and $\mathrm{F}=0.15$ (Figure 28) in 2017 scenarios. Catch estimates ranged from 11,000 t to 27, 000 t (Table 19).

A sensitivity stochastic projection was completed to estimate the probability that the fishing mortality rate in 2018 would not exceed an $F_{\text {ref }}=0.25$ and $F=0.15$ for a range of catch values and the 2019 biomass would not increase by 10\% compared to 2018 under a constant quota $(5,100 \mathrm{t})$ in 2017. The results of this scenario are summarized in Figure 29.

The deterministic projections for the sensitivity analyses conducted with a value of 54 million for the 2013 year class produced catch advice for Ages $1+$ of $9,666 \mathrm{t}$ in 2017 and 10,379 t in 2018 with $F_{\text {ref }}=0.25$, and for $F=0.15$ produced catch advice of $5,989 t$ in 2017 and $6,831 t$ in 2018 (Table 17 and 18).

## SOURCES OF UNCERTAINTY

Differences in the growth between the Bay of Fundy and the Scotian Shelf regions have been documented for this resource, and a recent analysis confirmed it is still appropriate to use separate age length keys (Stone and Hansen 2015). However, the defined survey strata used to evaluate growth differences between the Bay of Fundy and the Scotian Shelf are different from the statistical areas used to match length-weight and age length key relationships with catch data. The impact of this mismatch should be evaluated. Given that the location of future harvesting cannot be predicted, this growth mismatch could have effects on the accuracy of projections.
The Age 1+ model biomass estimate (biased adjusted) from the VPA and the survey index (not adjusted for $q$ ) were visually inspected to examine trends in the expected (VPA) and observed (survey) abundance for 2016 (Figure 30). The 1+ biomass from the VPA was used because it includes the 2013 year class (Age 3 in 2016); however, it is important to consider that abundance at Age 1 for 2016 was assigned as the most recent 10 years of geometric mean of recruitment at Age 1 (excluding the exceptional strong 2013 year class) and no error around the

Age 1 biomass was assumed. Due to the data assumptions Figure 30 was used to evaluate trends only, notably, the survey index of abundance decreased in 2016 when compared 2015, while the VPA abundance estimate suggested an increase in 2016.

The 2013 year class appears to be much stronger than anything previously observed, but there is uncertainty around this estimate given the retrospective, the small number of observations in both the survey and fishery, and the apparent mismatch between survey abundance estimates and the VPA in recent years. The CV is high for the VPA estimate of the 2013 year class ( 0.4 at Age 3 in 2016, Table 11). The future performance of the 2013 and 2014 year classes will impact the stock dynamics.

## RESEARCH RECOMMENDATIONS

The high M used in the assessment model could be aliasing fish moving to adjacent areas or deeper waters where the fishery or survey cannot catch them. Noteworthy is that the adjacent Haddock stock on Eastern Georges Bank also shows high total mortality (Z) on older (Age 8+) fish (Stone and Hansen 2015). Research on a possible mechanism for high M on older ages would help to improve understanding of the population dynamics of 4X5Y Haddock. In addition, research on changes in growth/productivity over time and factors influencing the production of exceptionally strong year classes would also be helpful.

## ACKNOWLEDGEMENTS

The authors wish to thank D. Swain for providing the ADMB source code to run VPA models with random walks in M and to P. Comeau for ageing the 4X5Y Haddock samples. Also, thanks to the reviewers and the attendees of the assessment of 4X5Y Haddock 2016 peer review meeting; their questions and suggestions greatly improved this document.

Table 7. The DFO Summer RV survey total biomass index (t) for 4X5Y Haddock calculated separately for Bay of Fundy strata (482-495), western Scotian Shelf strata (470-481) and both areas combined, 19702016. The average includes data from 1970-2016. A conversion factor of 1.2 has been applied to indices from 1970-1981 to account for vessel and gear changes.

| Year | Total Biomass Index (t) |  |  |
| :---: | :---: | :---: | :---: |
|  | Strata 482-495 (BoF) | Strata 470-481 (Western SS) | Strata 470-495 (Combined) |
| 1970 | 17,822 | 21,262 | 39,083 |

Table 8. The DFO Summer RV survey total abundance index at age (000's) for 4X5Y Haddock calculated separately for Scotian Shelf strata (470-481) and Bay of Fundy strata (482-495) then combined, 1970-2015. A conversion factor of 1.2 has been applied to indices from 1970-1981 to account for vessel and gear changes. Abundance at age data from 1985-2015 was used for assessment modelling.

Table 9. Weighted DFO Summer RV survey mean weight-at-age (kg) of 4X5Y Haddock for ages 0-14 calculated separately for Scotian Shelf strata (470481) and Bay of Fundy strata (482-495) then combined after weighting by total number, 1970-2015. Cells with dashes have no data available. Weight-atage (WAA) data from 1985-2015 was used for assessment modelling.

Table 10. Weighted mean length-at-age (fork length, cm) for the DFO Summer RV survey of 4X5Y Haddock for ages 0-12, calculated separately for Scotian Shelf strata (470-481) and Bay of Fundy strata (482-495) then combined after weighting by total number; 1970-2015. Cells with dashes have no data available.

|  | Age |  |  |  |  |  |  |  |  |  |  |  |  |

Table 13. Estimated population abundance-at-age and ages 4+ biomass from the VPA model formulation of $M$ fixed at 0.2 , except $0.3,0.6$, and 0.9 for ages 10-11+ for the 3 time blocks (2000-2004, 2005-2009, and 2010-2015, respectively) for 4X5Y Haddock. *The abundance at Age 1 for 2016 was an assigned value, as the most recent 10 years of geometric mean of recruitment at Age 1 (excluding the exceptional strong 2013 year class).

FIGURES

Figure 1. Map of the 4X5Y Haddock management area and Canadian Statistical unit areas for the Bay of Fundy (4Xqrs) and western Scotian Shelf (4Xmnop). Separate age length keys for the western Scotian Shelf and Bay of Fundy are used for calculating the catch at age and survey age-specific indices of abundance. Haddock landed from statistical areas 5ZEM and 5ZEJ are not included in the 4X5Y Haddock stock assessment.

Figure 2. Reported annual landings (t), fishing year landings (FY; April $1^{\text {st }}-$ March $31^{\text {st }}$ ) and TAC for the 4X5Y Haddock fishery, 1970-2015.

Figure 3. Percentage of annual landings (t) by gear type for the 4X5Y Haddock fishery, 1970-2015. TC 13 = otter trawl tonnage class 1-3; TC 4+ = otter trawl tonnage class 4+; LL = longline.

Figure 4. Annual landings (t) by Canadian statistical unit area for the 4X5Y Haddock fishery, 1985-2015.

Figure 5. Annual landings (\%) by gear sector for Canadian statistical unit areas representing the western Scotian Shelf (SS; 4Xmnop) and Bay of Fundy (BoF; 4Xqrs5Y) areas of the 4X5Y Haddock fishery, used in catch-at-age calculations for 1985-2015.

Figure 6. Distribution of 4X5Y Haddock catches (t) by gear type for 2005, 2010 and 2015.

Figure 7. 4X5Y Haddock landings (t) from small mesh otter trawl (cod end mesh size:110-112 mm diamond) and \% of total annual landings,1991-2015.

Figure 8. Catch-at-age for 4X5Y Haddock for ages 1-14, 1985-2015. The area of the circle is proportional to the catch at that age and year. Three examples of recent strong cohorts are highlighted: 2003 (yellow), 2010 (red), and 2013 (blue). Data from 1985-2015 was used for assessment modelling.

Figure 9. Commercial fishery mean weighted length-at-age (cm), calculated using the catch-at-age application (see text for details), for 4X5Y Haddock ages 2, 4, 6, 8, and 10 for 1985-2015.

Figure 10. Commercial fishery mean weighted weight-at-age (kg), calculated using the catch-at-age application (see text for details), for 4X5Y Haddock ages 2, 4, 6, 8, and 10 for 1985-2015.

Figure 11. $4 \times 5 Y$ Haddock commercial fishery catch at size by area (SS: Scotian Shelf; BoF: Bay of Fundy) and gear type (M: mobile; F: fixed) summed over year intervals, 1985-2015.

Figure 12. Distribution of 4X5Y Haddock catches (kg/tow) from the DFO Summer RV survey, a 10 or 6 (2010-2016) year average aggregated by 10 minute squares from survey Strata 470-495, 1970-2016.

Figure 13. The DFO Summer RV survey strata and area of coverage for Scotian Shelf (Strata 470-481, blue shading) and Bay of Fundy (Strata 482-495; pink shading) areas of 4X5Y.

Figure 14. Trends in the total biomass index $\pm$ standard error ( 000 t ), including all ages, from the DFO Summer RV survey for Scotian Shelf (Strata 470-481), Bay of Fundy (Strata 482-495) (A) and both areas combined (4X5Y; B) compared to the long term average for each series from 1970-2016. A conversion factor of 1.2 has been applied to total biomass estimated for 1970-1981 to account for vessel and gear changes.

Figure 15. Stratified total number per tow at age (1-13) for $4 X 5 Y$ Haddock from the DFO Summer RV survey, Bay of Fundy (BOF) and the Scotian Shelf (SS), 1985-2015. The patterned circle represents the 2013 year class at age 1 in 2014 and Age 2 in 2015. The area of the circle is proportional to the catch at that age and year. Abundance at age data from 1985-2015 was used for assessment modelling.

Figure 16. The DFO Summer RV survey mean length-at-age (cm) for the each area (Scotian Shelf and Bay of Fundy) for 4X5Y Haddock ages 3, 5, 7, and 9 for 1985-2015.

Figure 17. The DFO Summer RV survey mean weight-at-age ( kg ) for the each area (Scotian Shelf and Bay of Fundy); as well as the mean weighted weight-at-age (combined) for 4X5Y Haddock ages 3, 5, 7, 9, and 11 for 1985-2015. Mean weighted weights-at-age were calculated separately for Bay of Fundy and western Scotian Shelf strata then combined after weighting using total abundance at age from each area.

Figure 18. Comparison of the DFO Summer RV survey mean length-at-age and commercial fishery mean length-at-age (cm) for ages 3 and 5 (upper panel) and 7 and 9 (lower panel) for Haddock from the 4X5Y management area, 1985-2015.

Figure 19. Comparison of Fulton's condition factor (k) (weight/length ${ }^{3}$ ) for 28-55 cm Haddock from the Bay of Fundy and the western Scotian Shelf sampled during the DFO Summer RV survey, 1970-2016.

Figure 20. Natural mortality estimated for $4 X 5 Y$ Haddock from a VPA model with time-varying natural mortality (M) with 4 age groups: 1-3, 4-6, 7-9, and 10+.

Figure 21. Residuals from the ADAPT VPA model formulation for $4 X 5 Y$ Haddock of $M$ fixed 0.2 , except at $0.3,0.6$, and 0.9, for ages 10-11+ for the three 5-year times block (2000-2004, 2005-2009, and 20102015, respectively).

Figure 22. The retrospective analysis for fishing mortality (A), biomass (B), and the age 1 recruitment (C) from the ADAPT VPA model formulation of $M$ fixed at 0.2, except 0.3, 0.6, and 0.9, for ages 10-11+ for the three time blocks (2000-2004, 2005-2009, and 2010-2015; respectively) for 4X5Y Haddock. Changes are relative to the 2016 assessment.

Figure 23. Survey catchability $(q)$ at age estimated from ADAPT VPA model formulation of $M$ fixed at 0.2, except 0.3, 0.6, and 0.9 for ages 10-11+ for the three time blocks (2000-2004, 2005-2009, and 20102015; respectively) for 4X5Y Haddock.

Figure 24. The model estimated 1985-2016 (solid blue line) and projected 2017-2019 (dashed biomass lines), 4+ biomass for 4X5Y Haddock. The established $B_{\text {lim }}$ (black dashed reference line) is 19,700 $t$. The time series average 4+ biomass (black dotted reference line) is 32,258 $t$.

Figure 25. The most recent 5-year average, 2011-2015, survey average weight-at-age compared to the 2015 weight-at-age for ages 1-11 for 4X5Y Haddock.

Figure 26. Stochastic projection to provide the risk of exceeding $F_{\text {ref }}=0.25$ (A), the risk of exceeding $F=0.15$ (B), and the probability that the 2018 biomass will remain stable (C), and the probability that the 2018 biomass will not increase by $10 \%$ under different catch values in 2017 for 4X5Y Haddock.

Figure 27. Stochastic projection to provide the risk of exceeding $F_{r e f}=0.25$ ( $A$ ), the probability of the 2019 biomass remaining stable ( $B$ ), and the probability of the 2019 biomass not increasing by 10\% (C) for different catch values in 2018 under an $F=0.25$ in 2017 scenario for 4X5Y Haddock.

Figure 28. Stochastic projection to provide the risk of exceeding $F=0.15$ (A), the probability of the 2019 biomass remaining stable (B), and the probability of the 2019 biomass not increasing by 10\% (C) for different catch values in 2018 under an $F=0.15$ in 2017 scenario for 4X5Y Haddock.

Figure 29. Stochastic projection assuming constant catch, 5100 t for 2017, to provide the risk of exceeding $F_{\text {ref }}=0.25$ (A), the risk of exceeding $F=0.15(B)$, and the probability of the 2019 biomass remaining stable (C), and the probability of the 2019 biomass not increasing by $10 \%$ for different catch values in 2018 for $4 \times 5$ Y Haddock.

Figure 30. The total biomass index (000 t) $\pm$ standard error, including all ages, from the DFO Summer RV survey for 4X5Y (Bay of Fundy and Scotian Shelf combined) and the biased adjusted model estimated 1+ biomass for 4X5Y Haddock. The 95\% confidence interval of the model estimated 1+ biomass was included for the 2016 run of the VPA. The biased model estimated abundance at Age 1 for 2016 was assigned as the most recent 10 years of geometric mean (excluding the exceptional strong 2013 year class) and no error was assumed for the recruitment at Age 1. Due to the data assumptions this figure should only for examining trends and should not be used for absolute numbers.

## APPENDIX: RESULTS OF TESTING AGAINST REFERENCE COLLECTION

Appendix Figure 1. Ages assigned by primary 4X5Y Haddock ager for reference collection ages.

Appendix Figure 2. Agreement between primary 4X5Y Haddock ager and the reference collection ages (0-14).

[^0]:    ${ }^{1}$ Fishing year in 1999 was extended to March 3, 2000. TAC prorated upwards. Subsequent fishing years begin on April 1st.

    * Extracted October 2016

[^1]:    ${ }^{1}$ Mobile gears include all kinds of trawls (e.g. otter, midwater, shrimp) and pair Seine.
    ${ }^{2}$ Miscellaneous gears include trap, unknown gears, Dredge, Jigger, Pot, squid jig and weir.
