# THE PIT SLOPE MANUAL

The Pit Slope Manual consists of ten chapters, published separately. Most chapters have supplements, also published separately. The ten chapters are:

- 1. Summary
- 2. Structural Geology
- 3. Mechanical Properties
- 4. Groundwater
- 5. Design
- 6. Mechanical Support
- 7. Perimeter Blasting
- 8. Monitoring
- 9. Waste Embankments
- 10. Environmental Planning

The chapters and supplements can be obtained from the Publications Distribution Office, CANMET, Energy, Mines and Resources Canada, 555 Booth Street, Ottawa, Ontario, KIA OGI, Canada.

Reference to this supplement should be quoted as follows:

Ramsden, J., Cruden, D., and Herget, G. Pit Slope Manual Supplement 2-2 - Domain Analysis Programs; CANMET (Canada Centre for Mineral and Energy Technology, formerly Mines Branch, Energy, Mines and Resources Canada), CANMET Report 77-19; 60 p; Dec 1977.

# ACKNOWLEDGEMENTS

G. Herget was responsible for producing this supplement; address enquiries to him at: 555 Booth Street, Ottawa, KlA OGl, Canada.

This supplement was written by J. Ramsden, and D. Cruden with assistance from P. Buttuls and technical editing by A. Soo-Wong, D. Patterson and G. Herget.

Contractor: University of Alberta, Edmonton, Alberta.

The Pit Slope Project is the result of five years' research and development cooperatively funded by the Canadian Mining Industry and the Government of Canada.

The Pit Slope Group consisted of D.F. Coates\*, M. Gyenge\*, G. Herget, B. Hoare, G. Larocque, D. Murray, R. Sage\* and M. Service.

\*Pit Slope Group Leaders.

#### SUMMARY

This report documents a User's Manual for the domain analysis of structural data. Card decks are supplied separately. Documentation of the computer programs that comprise the system has been carried out to ASCE standards (ASCE Proceedings 99, SM3, 1973, pp 249-266).

Domain analysis proceeds in four stages and the computer programs documented are grouped in these four stages. In stage 1, four programs - DTFX, TRVL2, INPT1 and MAP3 - prepare files and define groups of observations. In stage 2, four further programs are introduced - WNST5, GRPK1, INPK1 and GRPS - which assist in the computation of group means and dispersions. Stage 3 requires three programs - DSPD, NNPL1 and WNDPLT3 - for the display of group means and dispersions. Stage 4 uses two further programs - HOMO and DDKY.

#### INTRODUCTION

1. This analysis defines the orientation domains of a particular discontinuity. The discontinuity type (fabric element) to be analyzed must first be identified and retrieved from the master data file before the domain-analysis procedure can begin. Observations of orientation of the discontinuity type within the study area are then divided into groups and each group is characterized by a mean and dispersion. Statistical tests are used to define the largest possible areas within which the means and dispersions of the groups are similar. These areas are subfabric domains. Since the statistical tests are based on Fisher's model, the distribution of poles to the fabric element within each group should be unimodal and axially symmetric.

2. The procedure may be conveniently divided into four stages which are described as: File Preparation and Definition of Groups, Computation of Group Means and Dispersions, Display of Group Means and Dispersions, and Definition of Domains and Characterization of Domain Subfabrics.

3. The following four Sections describe each of these four stages in detail.

# FILE PREPARATION AND DEFINITION OF GROUPS

4. Stage 1 is illustrated by the flow diagram in Fig 1, and consists of four steps.

5. Stage la. The file containing data for the fabric element, shown as uncorrected data file in Fig 1, is processed by the program DTFX. This produces a new data file in which every observation is associated with a distance from the traverse origin and observations on each traverse appear in order of increasing distance. This makes it possible to split traverses in the definition of groups.

6. Stage lb. One of the requirements of the statistical tests for homogeneity of group means and dispersions is that groups contain not less than five observations. To satisfy this requirement, a map is produced that shows traverses and the number of observations on each traverse. This in turn requires that program TRVL2 uses the master traverse file and the data file produced by DTFX to produce a new corresponding traverse file.

7. Stage lc. Program INPT1 reads the new traverse file and stores the data for program MAP3, which produces the map.

8. Stage ld. The groups are outlined on the traverse map, and the group specifications tabu-

lated in terms of traverse and observation numbers on each traverse.

9. Note that in all subsequent stages, references to the data files are taken to mean the new or adjusted data file, and all references to the traverse file are taken to mean the new traverse file.

#### PROGRAM DTFX

10. The program makes adjustments to a data file so that it is in a suitable form for areal analysis. The fabric data are examined one traverse at a time. Observations without corresponding distances are assumed to be uniformly distributed along the traverse. All observations on the traverse are then ordered by increasing distance. A flow diagram is given in Fig 2(a) and 2(b).

#### <u>Solution</u>

11. The fabric data are examined one traverse at a time. Those observations that have no corresponding distances associated with them are distributed uniformly along the traverse. The algorithm for doing this is as follows:

Fig 1 - Stage 1 - File preparation and definitions of groups

Fig 2(a) - Flow diagram for program DTFX - Part 1

- 1 = length of traverse
- n = number of observations without recorded
   distance
- x(i) = distance assigned to the i-th observation without distance
- a = 1/n b = a/2
- x(i) = (i\*a)-b :i=1,2,...n

All observations on the traverse are then ordered by increasing distance, and all the data for that traverse are written on the output file. The next traverse is then read from the input file and the process repeated. The first observation with zero distance following at least one observation with-zero distance is taken as the first observation for which distance is not recorded. This observation and all those that follow it in the traverse are assumed to have no distance recorded.

Fig 2(b) - Flow diagram for program DTFX - Part 2

#### Capabilities

12. Maximum number of observations in one traverse is 100. Those observations without distance must follow those with distance in each traverse.

#### Input

13. Unit 1 - tape or disk - input data file. Record length is 112 bytes. The records must all have the same length and format. Twenty-eight variables are read in each record with the format (A4, I4, 3A4, 2I3, I4, A4, A1, I4, 2I6, I5, 14A4). This file is created by CONVRT.

Variable no. Columns Specifications

2	005-008	integer,	traverse number
6	021-023	integer,	trend of
		traverse	
7	024-026	integer,	plunge of
		traverse	
8	027-030	integer,	length of
		traverse	
11	036-039	integer,	distance along
		traverse	
12	040-045	integer,	easting
13	046-051	integer,	northing
14	052-056	integer,	elevation

#### Output

14. <u>Unit 6 - printer</u> - statistics. Record length is 37 bytes. Prints number of traverses processed and the number of observations that were without distance.

<u>Unit 2 - tape or disk</u> - output data file. Record length is 112 bytes. Same as input data file (TAPE 1).

#### <u>Variables</u>

#### Storage Requirements

15. Input and output file formats described elsewhere.

Code	bytes	words
DTFX	5724 10205(buffers)	302B 4229
	15929	7257

#### PROGRAM TRVL2

16. The program reads traverse data from a traverse file. By simultaneously reading the data file, the program obtains the range of line numbers in the data file that corresponds to observations on each traverse. A new traverse file is produced containing this information. A flow diagram is presented in Fig 3.

#### Input

 Unit 1 - tape or disk - traverse identification from data file. Record length 808 bytes

Fig 3 - Flow diagram for program TRVL2

unformatted. This is usually the output of INPT1 or INPK1.

Unit 4 - tape or disk - traverse list. Record length defined by format. Identical records, one for each traverse. Records are composed of:

- a. double-word variable containing one to eight character identification of the traverse followed by
- b. single word variables that may contain other information about the traverse

Unit 5 - card reader - formats for reading and writing the traverse data files. There are two records, one format on each (one for reading, one for writing). The formats are in columns 3-102. See Sample input.

#### Output

put. Record length defined by format. Title of the traverse. New traverse file. Same variables as read on input unit 4, preceded by 4 full word integer variables containing:

- a. sequence number of traverse in input file 4.
- b. data file line number of first observation of this traverse
- c. data file line number of last observation on this traverse
- d. number of observations of this traverse.

#### Run Time

18. The program required 1.3 seconds of CPU time to process a data file containing 297 observations on 43 traverses.

#### PROGRAM INPT1

19. The program reads specified variables from an input file and writes the data in a convenient form for use by other programs in the areal analysis package. A flow diagram is shown in Fig 4(a) and 4(b).

<u>Unit 6,8 - tape, disk or card punch - printed out-</u> Fig 4(a) - Flow diagram for program INPTI - Part 1

Fig 4(b) - Flow diagram for program INPT1 - Part 2

20. INPT1 accepts as parameters the number of variables to be read from each record of the input file and the format for reading those variables. The first field in the format specification must refer to a line-type character and must be specified as Al. The given number of variables must include the line-type character. Since the data array is declared as integer, and some FORTRAN input routines will not allow data to be read into an integer variable with an F format code, ie, as a real number, all input data must be in integer form and all fields must be specified with an I format code. If it is desired to convert integers to real numbers before they are placed in the output file, an additional set of parameters may be added to the parameter card containing the input format. These parameters specifiy which input variables are to be converted to real numbers and how many decimal places each should have.

21. At each data record in the input file, the program reads the specified number of one-word variables using the specified format. The data are written unformatted onto the output file as a header record followed by data records. Each output data record except the last always contains the data from 100 input records.

#### Solution

22. The output data records are first written onto a scratch file. After all the input records have been read, the title record is written onto the output file, and the output data records are then copied from the scratch file to the output file.

23. After each set of input records, terminated by a delimiter record, has been processed, the program attempts to read another title record. If an end-of-file condition results, the program terminates normally. If another title record is read, the program continues as before. If the next record is not a title record, the program stops after writing an error message.

#### Capabilities

24. Maximum length of the given format is 60 characters. Maximum number of variables read from each input record is 10.

#### Input

<u>Unit 1 - tape or disk</u> - input data file. Record length defined by format. The file contains one or several sets of data records. Each set must be preceded by a title record and followed by a delimiter record. The title record must contain the letter T in column 1 (this is called the line type character).

<u>Unit 5 - card reader</u> - a single record up to 102 bytes long. Record length: 102 bytes formatted.

Col 1-2 contains the number of variables to be read, right-justified.

3-62 FORTRAN format for reading input data from

unit l.

- 63-102 up to 20 2-digit numbers. These numbers are interpreted in pairs: the first number of each pair is the number of a variable to be converted to a real number; the second number of the pair is the number of decimal places.
  - Example: '43' asks for the fourth variable (do not count the line-type character) to be divided by  $10^3$ . The result is placed in the output record as a real number.

<u>Unit 7 - scratch tape or disk</u> - scratch file. Record length: 8+400xNV bytes unformatted. Output data records are stored in this file until they are copied to the output file.

#### Output

<u>Unit 6 - printer messages</u> - record length: 35 bytes unformatted. The program writes the number of output records. Error messages are selfexplanatory.

<u>Unit 8 - tape or disk</u> - output file. Record length:  $8+400 \times NV$  unformatted. Output is written unformatted on this file as a header record followed by data records. Each header record contains four full word integers followed by the 120-byte title. The four integers are:

- a. the total number of words in this set of data
- b. the number, NV, of variables read from each input record
- c. the total number of input records read in this set of data
- d. the number of output data records following the header record.

Each data record contains 2 full word integers followed by the data from up to 100 input records. The integers contain:

- a. the number, N, of input records in this output record (100 max)
- b. the number of words of data in this output record = N x NV

The data are the variables from the input records in the order in which they were read.

#### Variables

NVAR	number of variables
FMT	format
IC	conversion factors
LINTYP	line-type character
NTOT	total number of data records read
NPHR	number of output data records (after title
	record)
N	number of data records in batch
DATA	array to contain the data
IV	number of variable to be converted to real
RDATA	array to contain real values - same loca-
	tion as DATA
ΙE	number of data words in data record
NN	number of data words in entire sample

#### Storage Requirements

25. The arrays DATA and RDATA occupy the same storage.

Code	bytes	words	
 INPTI	2400	1280	
	<u>12246(</u> buffers)	5286	
	14646	6566	

#### PROGRAM MAP3

26. The program draws a map with coordinate grid lines showing either (1) survey traverses, (2) strikes of discontinuities, or (3) threedimensional orientations of discontinuities. Three-dimensional orientations are represented by a line whose azimuth and length are those of a line drawn on an equal-area projection from the centre of the projection to the point representing the given orientation. A flow diagram is given in Fig 5.

#### Solution

27. MAP3 determines the maximum and minimum X and Y values from the data. It then determines the position of the first grid line above the maximum X value, and the position of the first grid line below the minimum X value, using the given interval between grid lines. This is repeated for the Y values. The four grid lines so

Fig 5 - Flow diagram for program MAP3

determined become the borders of the map. This border is drawn, as well as all intermediate grid lines, and a title is written below the lower border. The data points are then plotted. Optimization of plotting is achieved in the following way: Using the extreme X,Y values corresponding to the borders of the map, the program subdivides the whole rectangular region into a 60 by 60 grid, determines the number of observations within each grid square, and sets up pointers to locate all observations within each grid square. This enables the program to do a scan on the 60 by 60 matrix to optimize plotting.

28. The scale of the map is determined by a scale factor read from the parameter card. This scale factor specifies the number of data units that are to correspond to one inch on the map.

29. Beside each data point the program writes one number and one character string of up to four characters. If the number is zero, it is not plotted. From each data point a line is drawn with azimuth A and length, L. A and L are determined from the data items NUM1 and NUM2 associated with the data point, in a way determined by the parameter MODE.

#### Capabilities

30. Maximum number of data points in one map is 1500.

#### Program Options

31. If MODE= 1 (traverses) A=NUM1 and L=NUM2/ SCALE (same scale as coordinates). If MODE=2 (strikes) A=NUM1 and L=0.5. If MODE=3 (threedimensional directions) A=NUM1 and L=PROJARD(NUM2, DPI), where PROJARD(NUM2,DPI) is the distance on a Lambert equal-area projection with radius DPI from the centre of the projection to a point representing a plunge of NUM2 degrees. DPI is read from the parameter card.

32. Optional printout of the input and certain derived data are controlled by the LIST parameter.

#### Input

<u>Unit 1 - tape or disk</u> - data unformatted, as written by program INPT1, INPK1 or DSPD. Record length: 2408 bytes, unformatted.

<u>Unit 5 - card reader</u> - record length: 50 bytes formatted. One record containing:

formatted.	Parameter lis	t and messages. Input	XLIMIT	(X)
parameters.			Kesi	ets the derault limit of plotting in the

X-direction to X in.

NUMBER(X,Y,H,R,T,N)

Writes the real number, R, with N decimal places at the location X,Y with a character height of H, making an angle of T degrees with the positive x axis (counter-clockwise).

#### LINE(X,Y,N,I,J,K,)

Given N data points whose coordinates are in every i-th word of the vectors X and Y, either draws a line through the points (J=0), or draws the symbol number K at each point (J < 0) or both (J > 0).

#### SYMBOL(X,Y,H,IC,T,N)

Starting at the point X,Y and using a symbol height of H in., either draws N characters stored in EBCDIC in the array IC (N > 0) or draws symbol under IC (N=1) or draws symbol under IC with a line from the current pen position (N=-2). The symbols make an angle of T degrees with the positive x axis (counter-clockwise).

# COMPUTATION OF GROUP MEANS AND DISPERSIONS

33. Stage 2 of domain analysis, is illustrated by the flow diagram in Fig 8 and consists of three steps.

34. Stage 2a. Program INPT1 reads the data file and stores the data required by program WNST5 which computes statistics for the whole data file. The eigenvectors for the whole data file are stored for use in Stage 2c and in Stage 3a.

35. Stage 2b. Using the group specifications and the traverse file, program GRPK1 computes the group keys, ie, the line-numbers in the data file corresponding to each group of observations outlined on the map.

36. Stage 2c. Program INPK1 reads the data file under control of the group keys and stores the data required by program GRPS, which computes the mean and dispersions of each group.

#### PROGRAM WNST5

37. The program computes axis statistics and vector statistics for weighted points on the hemisphere. A flow diagram is presented in Fig 9.

38. WNST5 calls the subroutines DCPM1 to compute the data cross-product matrix, then subroutine ESTAT1 to estimate population parameters using Bingham's model. This subroutine also tests

Fig 8 - Stage 2 - Computation of group means and dispersions

Fig 9 - Flow diagram for program WNST5

the hypotheses of uniformity and axial symmetry using the eigenvalues of the data cross-product matrix. Depending on the results of these tests, the program performs a more sensitive test for axial symmetry, using Kuiper's statistic, by calling the subroutine CIRC1.

39. Fisher statistics are obtained by calling subroutine SCOM1 to compute sums of components, subroutine PSTAT1 to estimate population parameters using Fisher's model, and subroutine CIRC1 to test for axial symmetry about the Fisher mean.

# <u>Solution</u>

See subroutine documentation in source listing.

#### <u>Capabilities</u>

Maximum number of data points in one sample is 2000.

#### Input

<u>Unit 1 - tape or disk</u> - record length: 1600 bytes unformatted. Input data. Unformatted records containing direction cosines and weights for up to 100 points. The sequence direction cosines, weight (four full word real numbers) is repeated for each data point. This file is written by program INPT1 or INPK1.

#### <u>Output</u>

<u>Unit 6 - printer</u> - record length: 76 bytes formatted. Statistics. All computed statistics are written on this I/O unit, with printer carriage control.

<u>Unit 7 - disk or card punch</u> - record length: 30 bytes formatted. Eigenvectors. The eigenvectors of the data cross-product matrix are written on this unit for later use by other programs. Three formatted records are written, each containing the direction cosines of one eigenvector in the normal sequence (north, east, down). The sequence of eigenvectors is such that the associated eigenvalues are in ascending order.

#### Subroutines

FSTAT1 Given the sums of components of a set of vectors, computes the length, direction cosines and angular co-ordinates of the resultant vector. FSTAT1 also computes the concentration parameter and confidence radius of the mean assuming Fisher's distribution. FSTAT1 calls RTSP and XKF. RTST computes the angular co-ordinates of the resultant, and XKF estimates the concentration parameter of the population. Calling sequence: CALL FSTATI(TITLE,N,SW, U,E,S,T,XK,CR, IPRINT) TITLE = 120-byte title

- N = number of data points
- SW = sum of weights of the data points
- U = vector of sums of components
- E = vector of direction cosines returned
- S = vector of angular co-ordinates returned. It contains trend and plunge, followed by dip direction and dip, of the perpendicular plane.
- T = a rector returned containing l. length of the resultant vector, and 2. length of the resultant divided by SW.
- XK = estimated concentration parameter returned.
- CR = confidence radii of mean returned.
- IPRINT = print out parameter provided by calling routine IPRINT is less than zero if there is to be no print out. IPRINT is greater than or equal to zero for a printout, and the value of IPINT is the I/O unit.

KUIP2 See source

- XK1 Function, See source
- ROTMAT See CONVRT
- XK3 Function, See source
- BSTATC See source
- RSTP See DSPD
- ANDC Converts from spherical to rectangular coordinates for points on the unit sphere. Calling sequence: CALL ANDC(T,P,J1,A,B,C, J3,N)
  - T = vector of horizontal angles
  - P = vector of vertical angles
  - - Jl is greater than zero if the input units are in degrees. It is less than zero if the input units are radians.
  - J2 = second input code.
    - = 1 if input type is trend and plunge
       of line
    - = 2 if input type is dip direction and dip of plane.

= 3 if input type is strike and dip of plane.

In cases 2 and 3 the pole is the unit hemisphere and J2 is greater than zero if the domain of input is the unit sphere; J2 is less than zero if the domain of inputs is the unit hemisphere.

- A = vector of first direction cosines returned
- B = vector of second direction cosines
- C = vector of third direction cosines
- J3 = output code of spacing, in words, of vectors A, B, and C
- N = number of data points input.

#### PROGRAM GRPK1

40. Using a list of the traverses in each domain and a list of the observations in each traverse, this program generates keys containing the numbers of the observations in each domain. A flow diagram is shown in Fig 10.

#### Solution

41. The program reads from the traverse file the range of data-file line numbers for each traverse. It then reads group definitions, one at a time. Each group is defined by traverse numbers and observation numbers on each traverse. Travers es specified for a group are processed in order of increasing traverse number, so that line numbers in the key will be in sequence. This traverse number is not the field traverse number, but one assigned by TRVL2 to place traverses sequentially in the data file. If the entire traverse is not to be included, the range of line numbers to be included in the key is computed. The line numbers in this range are added to the key.

42. The number of the traverse just processed is replaced by 10000 and the group definition again searched for the smallest traverse number. When all the traverses included in the group have been processed, the key is written out and the next group definition is read.

#### <u>Capabilities</u>

43. Maximum number of traverses in the traverse file is 999. Maximum number of traverses in one group is 10. Maximum number of line numbers

Fig 10 - Flow diagram for program GRPK1

in key is 20.

# Input

<u>Unit 1 - tape or disk</u> - record length: 121 bytes, formatted. Traverse numbers and line number ranges. One record for each traverse containing:

Column	Contents
2-5	traverse number
13-16	starting line number for traverse
17-20	ending line number for traverse

#### These data created by TRVL2.

<u>Unit 2 - card reader</u> - record length: 120 bytes formatted. Group definitions. One record for each group. Each record contains 120 characters, or 30 in each %, 4 character fields.

A group may have up to 10 traverses. Each traverse has 3, 4 character fields:

- field l is the traverse number
- field 2 is the number of the first observation to be included. If this field is blank or zero, the first observation of the traverse is assumed.
- field 3 is the number of the last observation to be included. If this field is blank or zero, the last observation of the traverse is assumed.

Each field is right justified.

#### <u>Output</u>

<u>Unit 6 - printer</u> - record length: 121 bytes formatted. Error messages. If the number of observations indicated for inclusion in a traverse is greater than the number of observations taken for that traverse, an error message is produced. The program stops immediately.

<u>Unit 7 - disk or card punch</u> - record length: 80 bytes formatted. Key. Writes a single key for each group of traverses. These keys are used as input to the program INPK1.

#### Subroutines

WRITEK Writes a set of half-work integers in a special format: All records are 80 bytes long, sequenced in positions 78-80 Record 1: 1-72 = first 72 bytes of title Record 2: 1-48 = last 48 bytes of title 53-56 = LENFIL61-64 = LENKEYOther records: 1-72 keys; usually 18 Calling sequence: CALL WRITEK(IOU, TITLE, LENFIL, LENKEY, KEY) 100 = I/O Unit to be written on TITLE = 120 bytes title LENFIL = size of universe to which the set of data belongs. LENKEY = size of set of the data KEY = set of key data

#### <u>Variables</u>

FMT	format for reading traverse file
TITLE	title
М	number of first observation on traverse
N	number of last observation on traverse
LENFIL	number of observations in survey
I GROUP	counter for domains
LENKEY	number of observations in domain
L	array of traverse numbers in domain
NT	number of traverses in domain
MIN	smallest traverse number in domain
KEY	array of observation numbers in domain

#### Storage Requirements

TOTAL	6920	15380	6914	

#### PROGRAM INPK1

44. The program reads specified variables from an input file using a key and writes the data in a convenient form for use by other programs in the areal-analysis package. A flow diagram given in Fig ll(a) to (c).

45. INPKI accepts as parameters the number of variables to be read from each record of the input file and the format for reading those variables. The first field in the format specification must refer to a line-type character and must be speci-The specified number of variables fied as Al. must include this field. Because the data array is declared as integer, and some FORTRAN input routines will not allow data to be read into an integer variable with an F format code, ie, as a real number, all input data must be in integer form and all fields must be specified with an I format code. If it is desired to convert integers to real numbers before they are placed in the output file, an additional set of parameters may be added to the parameter card containing the input format. These parameters specify which input variables are to be converted to real

Fig ]](a) - Flow diagram for program INPK - Part ]

numbers and how many decimal places each should have.

46. Which records of the input file are read is determined by a key of record numbers. At each record of the input file whose number appears in the key, the program reads the specified number of full word variables using the specified format. The data are written unformatted into the output file as a header record followed by data records. Each output data record except the last always contains the data from 100 input records.

#### <u>Solution</u>

47. The output data records the first written onto a scratch file. After all the input records have been read, the header record is written onto the output file, and the output data records are then copied from the scratch file to the output file.

48. If the first byte of the first input record contains the letter T, this record is assumed to be a title record and counting of input records begins with record 2; otherwise counting

Fig 11(b) - Flow diagram for program INPK - Part 2

Fig 11(c) - Flow diagram for program INPK - Part 3

of the input records begins with record 1. Since only those input records are read whose numbers appear in the key, an end-of-file condition resulting from an attempt to read the input file always indicates an error, and the program stops after printing a message. After processing the input records as directed by a key, the program attempts to read another key. If an end-of-file conditions results, the program stops normally. If another key is read, the input file is rewound and the process repeated using the new key. In this way, any number of sets of data may be extracted from the input file and written sequentially on the output file.

#### **Capabilities**

49. Maximum length of the given format is 60 characters. Maximum number of variables read from each input record is 10. Maximum number of variables read from each input record is 10. Maximum number of input record numbers in one key is 5000.

#### Input

<u>Unit 1 - tape or disk</u> - record length: determined by format from unit 5. Output from DTFX. Input data file. All records have the same format unless the first record is a title record, in which case the first record contains the letter T in column 1 (This is the line type character) and a title in column 2-121.

<u>Unit 2 - card reader</u> - record length: 80 bytes formatted. Keys. This is the output file from GRPK1, unit 7.

<u>Unit 5 - card reader</u> - record length: 102 bytes, formatted. Parameters. One record containing:

Contents

1-2	number of variables to be read,
	right justified.
3-62	a FORTRAN format describing how to
	read data from unit 1.
63-102	up to 20, 2-digit numbers (right-
	justified). These numbers are in-
	terpreted in pairs: The first is
	the number of the variable to be
	converted to a real number; the
	second is the number of decimal
	places.
	Example:
	'43' asks that the fourth variable
	(not counting the first character,
	which is the line type character)
	divided by $10^3$ and the result
	placed in the output record as a
	real number.

#### Output

<u>Unit 6 - line printer</u> - record length: 35 bytes, formatted. Messages. The program writes the number of output data records. Error messages are self-explanatory.

<u>Unit 7 - tape or disk</u> - record length:  $8 + 400 \times$  NV unformatted. Scratch file. Output data records are stored in this file until they are copied to the output file.

<u>Unit 8 - tape or disk</u> - record length 8 + 400 x NV, unformatted. NV = number of variables. Output file. Output is written unformatted on this file as a header record followed by data records. Each header record contains four full word integers followed by the 120 byte title. The four integers contain:

- (1) total number of words in this set of data
- (2) number, NV, of variables read from each input record
- (3) total number of input records read in this set of data
- (4) number of output data records following the header record.

Each data record contains two full word integers followed by the data from up to 100 input records.

#### Subroutines

READK	reads a set of integers formatted by the										
	subroutine WRITEK.										
	Calling sequence: CALL READK (IOU,TITLE,										
	LENFIL,LENKEY,KEY)										
	IOU = I/O unit to be read										
	TITLE = title of the set of data to be										
	read										
	LENFIL = size of the universe to which the										
	set belongs										
	LENKEY = size of set										
	KEY = the set of data										
	double return from this routine										
	return 1 return taken if end-of-file is										
	encountered at the first record										
	return 2 return is taken if end-of-file is										
	encountered after the first rec-										
	ord (set is not complete) of										
	records is out of sequence.										

#### <u>Variables</u>

NVAR	number of variables
FMT	format
IC	conversion factors
LINTYP	line-type character
TITLE	array to contain title
TITL	flag to indicate title present
NFILE	number of records in data file
LENK	number of records to be read
KEY	array of record numbers
NTOT	total number of data records read
NPHR	number of output data records (after title
	record)
Ν	number of data records in batch
DATA	array to contain the data
IV	number of variable to be converted to real
RDATA	array to contain real values - same loca-
	tions as DATA
IE	number of data words in data record
NN	number of data words in entire sample

#### Storage Requirements

The arrays DATA and RDATA occupy the same storage.

#### PROGRAM GRPS

50. This program computes statistics for each domain for areal analysis. A flow diagram is given in Fig 12.

51. GRPS accepts as parameters the format of the output and the pole of the hemisphere to be used for computing statistics. The data are read from a file written by program INPK. As the data for each group are read, statistics are computed by calling subroutines SCOM1 and FSTAT1. Since these are vector statistics, the pole read from the parameter card is used for assigning sense to the axes.

Fig 12 - Flow diagram for program GRPS

#### Solution

52. See subroutine documentation in source listing.

#### <u>Capabilities</u>

53. Maximum number of observations in any group is 100.

#### Input

<u>Unit 1 - tape or disk</u> - record length: 2408 bytes, unformatted. Input data file as written by INPK1. <u>Unit 3 - card reader</u> - record length: 30 bytes, formatted. Pole of hemisphere. Three records containing in the usual sequence, direction cosines of pole, one direction cosine per record in columns 21-30 with decimal point.

<u>Unit 5 - card reader</u> - output format. Columns 3-102. See below.

#### <u>Output</u>

<u>Unit 8 - tape or disk</u> - record length: determined by format. Output data file. Format determined by given format specification on unit 5. Variables written are:

- (1) number of group
- (2) mean coordinate of group
- (3) mean Y coordinate of group
- (4) number of observations in group
- (5) sum of weights times 10
- (6) three sums of components in the usual sequence times 10
- (7) three direction cosines of mean direction, in the usual sequence, times 10<sup>6</sup>
- (8) length of resultant divided by sum of weights times 10<sup>6</sup>
- (9) trend and plunge of mean direction as integers
- (10) concentration parameter as integer.

#### Subroutines for GRPS

#### SCOM1:

Computes the sums of the components of a set of vectors. This subroutine calls ANDC.

Calling sequence:

CALL SCOMT(DC,W,N,V,JM,U)

- DC = 3\*N matrix of direction cosines
- W = vector of weights
- N = number of data points
- V = vector of length 2 or 3 see JM
- JM = 0 if directions used are given
  - = 1 if directions are to be adjusted and V contains trend and plunge of center of hemisphere in degrees.

- = 2 if directions are to be adjusted and V contains trend and plunge of centre of hemisphere in radians.
- = 3 if directions are to be adjusted and V contains direction cosines of centre of hemisphere.
- U = vector of length 3 that returns the sums of the components.

#### SRF:

Converts real numbers to integers, multiplying by a given power of 10 and rounding: Each real number is multiplied by 10\*\*IF and then rounded. If the resulting integer is greater than MAX, it is set to MAX, if it is less than -MAX, it is set to MAX.

- Calling sequence:
  - CALL SRF(RL,IN,N,IF,MAX)
  - RL = vector of real numbers. They may be in same location as IN, and may be positive or negative.
  - IN = vector of returned integers.
  - N = number of numbers to be processed.
  - IF = power of 10 by which the numbers are to be multiplied.
- MAX = the maximum value to which resulting integers are truncated.

#### Function:

TAB1

Looks up and interpolates a one-dimensional table. If X is beyond the range of the table, the returned value is the extreme value of B in the table.

Calling sequence:

- Y = TAB1(X,A,B,N)
- X = given value with which to enter table
- A = vector containing the column of the table in which X is to be found
- B = vector containing the column of the table from which the returned value (TAB1) is to be obtained.
- N = number of rows or entries in the table.
- TAB1 = the value of the function is the value obtained from the table.

# DISPLAY OF GROUP MEANS AND DISPERSIONS

54. Generation of displays in the observations and/or the group means and dispersions, both on maps and as point diagrams and density diagrams, constitutes Stage 3 of the procedures as shown in Fig 14, Display of the group data is illustrated; if the group data file is replaced by the data file and the format on the parameter card changed appropriately, the flow diagram will illustrate display of the individual observations.

55. Stage 3a. Program INPT1 reads the group data file and stores the information required by program DSPD. This program prepares data for the display programs, including rotation of the data so that the overall mean is vertical using the eigenvectors for the whole data file produced in Stage 2a.

56. Stage 3b. Program NPPL1 produces point diagrams on the plotter, program WNDPLT3 produces density diagrams on the printer, and program MAP3 produces a plotted map. Each data point on this map is shown as a line that begins at the point of observation, ie, the centre of the group in the case of group means, whose azimuth is the trend of the pole of discontinuity, and whose length is the distance from the centre of an equal-area projection to the projected pole.

#### PROGRAM DSPD

57. To read a data file written by program INPTI or INPKI and output four data files suitable for input to programs WNDP3, NPPLI and MAP3. A flow diagram is presented in Fig 15.

58. DSPD reads a rotation matrix and two parameters. Each block of data read from the input file is written onto output files 10D and IMA. The data is then rotated using the rotation matrix, and the rotated data written onto output files 10DR and IMAR. Files 10D and 10DR are suitable for input to programs WNDP3 and NPPL1; files IMA and IMAR are suitable for input to program MAP3.

#### Solution

See options.

#### Capabilities

No restrictions.

#### **Options**

59. If the input parameter has a value of 1, the input data are assumed to contain the direction cosines of lines and the trends and plunges of the lines. The data are output as read. If

Fig 14 - Stage 3 - Display of group means and dispersions

the input parameter has a value of 2, the input data are assumed to contain the direction cosines of the poles to planes and the dip directions and dips of the planes. The dip directions and dips are replaced by the trends and plunges of the poles to the planes before the data are written. After rotation, new trends and plunges are computed from the direction cosines. If the output parameter is not zero, all the numbers for display on the map are replaced by zeros. If the output parameter is neither zero nor 1, all the labels to be plotted on the map are replaced by blanks.

Fig 15 - Flow diagram for program DSPD

# Input

<u>Unit 2 - card reader</u> - record length: 30 bytes, formatted. Rotation matrix. Three records, each containing the corresponding column (1, 2, or 3) of the matrix as three real numbers:

lara column	contents
1-10 ro	w 1, column (1, 2 or 3)
11-20 ro	w 2, column (1, 2 or 3)
21-30 ro	w 3, column (1, 2 or 3)

Column	Contents
1	input parameter
	1-input is direction cosines of
	lines and the trends and plunges
	of the lines.
	2-input is direction cosines of
	the poles to planes and the dip
	directions and dips of the planes.
	for more information see program
	options.
3	output parameters.
	$\neq$ 0 all numbers on the map are re-
	placed by zeroes.
	≠ O and ≠ all the labels to be
	plotted are replaced by
	blanks.
	See program options.
<u>Unit 7 - ta</u>	ape or disk - record length: 4008, un-
formatted.	Input data file. This file is created
by INPT1 a	and INPK1. Variables for each observa-
tion are:	

- (1) three direction cosines
- (2) weight
- (3) easting
- (4) northing
- (5) number to appear on map
- (6) label to appear on map
- (7) trend or dip direction (depending on input parameter)
- (8) plunge or dip (depending on input parameter)

#### Output

<u>Unit 6 - line printer</u> - record length: 62 bytes, formatted. Messages. If the number of variables in the input data file is not 10, an error message is written and the program stops immediately.

<u>Unit 3 - tape or disk</u> - record length: 1608 bytes, unformatted. Data file for orientation diagrams. Variables for each observation are: three direction cosines, weight. <u>Unit 4 - tape or disk</u> - data file for orientation diagrams rotated. Same as unit 3 output except rotated direction cosines are used.

<u>Unit 8 - tape or disk</u> - record length: 2408, unformatted. Data file for map. Variables for each observation are: easting, northing, number to appear on map, label to appear on map, trend, plunge.

<u>Unit 9 - tape or disk</u> - data for map, rotated. Same as unit 8 output, except rotated trend and plunge are used.

#### Subroutines

#### RTSP

Converts from rectangular to spherical co-ordinates.

Calling sequence:

- CALL TRSP(A,B,G,J1,T,P,R,J2,J3,N)
- A = vector of X components.
- B = vector of Y components.
- G = vector of Z components.
- J1 = input description parameter of the spacing in words of components. in vectors A, B and G.
- T = vector of horizontal angles.
- P = vector of vertical angles.
- R = vector of distances from origin.
- J2 = first output description parameter of spacing of output words in vectors T and P. J2 is greater than zero if the output units are to be in degrees. J2 is less than zero if the output units are to be in radians.
- J3 = second output description parameter.
  - = 1 if output type is to be trend and
    plunge.
  - = 2 if output type is to be dip direction and dip.
  - = 3 if output type is to be strike and dip.

J3 will be greater than zero if the domain is the sphere, and less than zero if the domain is the hemisphere.

N = number of data points.

SRF See GRPS.

GMPRD See CONVRT.

Variable	25
RM	rotation matrix
КК	first input parameter
KL	second input parameter
NN	number of numbers in input record
NV	number of variables in input

#### PROGRAM NPPL1

60. The program generates commands for a digital incremental plotter to produce a point diagram on non-polar orientations on Lambert's equal-area projection. A flow diagram is shown in Fig 16(a) and (b).

#### Solution

6]. The orientations must be given as direction cosines. These are converted into X,Y coordinates on the projection by the subroutine RTXYEQ. The projection is horizontal unless defined otherwise by a parameter card. If a non-horizontal projection is requested, the data are rotated before the subroutine RTXYEQ is called.

#### Capabilities

62. Maximum number of points in any plot is 1000.

#### Input

<u>Unit 1 - tape or disk</u> - record length: 1608 bytes, unformatted. Data. As written by programs INPT1, INPK or DSPD. As many samples as desired may follow sequentially. One plot will be produced for each sample.

<u>Unit 4 - card reader</u> - record length: determined by format from unit 5. Normal to projection plane. Used only if a P or Q parameter card is supplied with a non-position number in the fourth numeric field of parameter unit 5.

Format given on parameter card.

formatted. Parameters. One or more cards of format:

Column	Contents
]*	nbn
2-11	trend or first direction cosine
12-21	plunge or second direction cosine
22-31	blank of third direction cosine
32-40	Code:
	$_{\pm}$ l.O if trend and plunge given
	in degrees.
	± 2.0 if trend and plunge given
	in radians.
	± 3.0 if direction cosines given
	code 0 if information is on par-
	ameter card.
	code O if information to be read
	on unit 4.
41-80	format for reading unit 4, if re-
	quired.

\* If this parameter card is supplied with a Q in

Fig 16(a) - Flow diagram for program NPPL1 - Part 1

column 1, two plots will be produced, one using the horizontal projection plane and one the specified projection plane.

#### Output

<u>Unit 6 - printer</u> - record length: 81 bytes, formatted. Error messages. <u>other - plotter or plot</u> tapes - output from plot-

Fig 16(b) - Flow diagram for program NPPL1 - Part 2

ting subroutines. Unit number and device requirements depending on the plotting subroutines.

#### Variables

A	parameter code
х	parameters
ALPHA	alphanumeric parameter
вотн	flag to indicate two plots required
ROTAT	flag to indicate rotation required

RM rotation matrix

- IPLOT counter of plots
- NN number of data words in sample
- NV number of variables in output
- NO number of observations in sample
- TITLE array to contain title
- DC direction cosines of data points
- W weights of data points
- N number of observations in sample
- XP,YP coordinates of center of projection
- DCR rotated direction cosines
- External References: The following subroutines from the plot library:
- PLOT(X,Y,J).
  - Moves the pen from its current position to the point (X,Y) with pen up (J=3) or down (J=2). Plot origin is reset to (X,Y) if J < 0.
- NUMBER(X, Y, H, R, T, N).
  - Writes the real number R with N decimal places at the location X,Y with a character height H making an angle of T degrees with the positive x axis (counter-clockwise).
- SYMBOL(X,Y,H,IC,T,N).
  - Starting at the point X,Y and using a symbol height, H in., either draws N characters stored in EBDIC in the array IC (N > 0) or draws symbol number IC (N=-1) or draws symbol number IC with a line from the current pen position (N=-2). The symbols make an angle of T degrees with the positive x axis (counter-clockwise).

#### CIRCLE(X,Y,A,B,C,D,E).

Draws a circular or spiral arc (solid if E = 0.0, dashed if E = 0.5) starting at the point (X,Y). A and B are the angles measured counter-clockwise from the positive x axis to the radius at the start of the arc and the radius at the end of the arc respectively. C and D are the corresponding radii in inches.

#### Subroutines

#### ROTMAT

See CONVRT.

#### RTXYEQ

See source listing.

#### VRM1

Returns the rotation matrix that will rotate a

given direction to the vertical. The trend and plunge of the axis of rotation and the angle of rotation are computed, and the subroutines ROTMAT and RTSP are called.

Calling sequence: CALL VRM1(V,M,J)

- V = vector of length 2 or 3. See J.
- M = returns rotation matrix
- - = 2 if V(1),V(2) contain trend and plunge in radians
  - = 3 if V(1),V(2),V(3) contain direction
    cosines

#### PROGRAM WNDPLT3

63. For weighted, non-directed orientations, the program produces on the line printer equalarea projections of point density having a high density of counting locations. A flow diagram is presented in Fig 17(a) to (c).

64. The plane of the projection is horizontal, unless a parameter card is given redefining the projection plane. In this case the directions are rotated before being plotted. The program uses by default a 1 per cent counting circle, a contour

Fig 17(a) - Flow diagram for program WNDPLT3 - Part 1

interval of 1 per cent, and the following characters to represent successive contour intervals 0-1 per cent, 1-2 per cent, and so on: "1234567890abc defghijklmnopqrstuvwxyz\*\*\*\*". Any of these defaults may be overridden by appropriate parameter cards.

65. The input data must include weights. Unless otherwise directed, the program uses these weights in the computations. A parameter card may be used to indicate that the weights are to be truncated at some specified upper limit, or that the weights are to be set equal to 1.

Fig 17(b) - Flow diagram for program WNDPLT3 -Part 2

#### Solution

66. To map the density of points on the sphere, a density estimate is computed at each of a number of pre-determined counting locations. For unweighted points, the density estimate at a particular location would be obtained by counting the points falling inside a pre-determined area, the counting circle, surrounding the location. The density estimate is usually obtained by expressing this count as a percentage of the total number of points. This program obtains a density estimate for weighted points by summing the

Fig 17(c) - Flow diagram for program WNDPLT3 -Part 3

weights of the points falling inside the area and expressing this sum as a percentage of the total of the weights of all the data points. The density estimates are printed in the form of an equal-area projection.

67. This program employs a print matrix consisting of 3713 print positions: 47 lines with 79 print positions on each. Printed six lines to the inch, the matrix is approximately eight inches square. The equal-area projection is a circle with a 10 cm radius centred on the print matrix. Every print position whose centre lies within the circle represents a counting location of which there are 2933. The counting locations are defined by direction cosines, which are read in by the program at the start of each run.

68. With such a large number of counting locations it is inefficient to compare every counting location with every data point in the counting The number of comparisons is thus reprocess. duced. For a particular data point, those counting locations that are to be incremented lie within a circle on the sphere whose projection approximates an ellipse that has its greatest size when the data point lies in the plane of projection. Before beginning the counting procedure, the program computes the maximum dimension, m, for the ellipse in this case. For each data point, the program computes XP, YP, the x and y coordinates on the print matrix of the projection of the data point, then determines the submatrix of the print matrix that lies inside the square bounded by X=XP-M, Y=YP+M, Y=YP-M. X=XP+M. This square wholly contains the projection of the counting circle centred on the data point. Each counting location represented in this submatrix is then tested by computing its angular distance from the data point and comparing this with the radius of the counting circle. This process is repeated in a slightly different form if the data point is close enough to the horizontal to affect counting locations on the diametrically opposite part of the projection.

69. After the counting procedure is completed, the program constructs the plot, line by line, by expressing each count as a percentage of the total weight and then placing the appropriate character in the corresponding print position. A contour interval and a string of characters are supplied to the program on parameter cards. As an enhancement to the visual impact of the plot, characters representing higher densities are overprinted, the number of overprintings increasing with the density value.

#### <u>Capabilities</u>

70. No restrictions.

# Input

<u>Unit 1 - tape or disk</u> - record length: 1608 bytes, unformatted. Data. As written by program INPT1, INPK1, or DSPD, as many samples as desired. One plot will be produced for each sample.

<u>Unit 3 - tape or disk</u> - record length: 80 bytes, formatted. Direction cosines of counting locations. A file of direction cosines is supplied with this set of programs, filename: DIRECTIONCOSINE.

<u>Unit 4 - card reader</u> - record length: determined by format. Normal to projection plane. The contents and format of the single record are described under "P" option under program options.

<u>Unit 5 - card reader</u> - record length: 80 formatted. Parameters. All parameter cards are optional because all parameters have default values. The reading of parameter cards is determined by a

blank card or an end-of-file (7/8/9). One parameter record must be supplied for each parameter for which a value is to be specified. See Program Options.

#### <u>Output</u>

<u>Unit 6 - printer</u> - record length: 42 bytes, formatted. Messages. Error messages are selfexplanatory.

<u>Unit B - printer</u> - record length: B4 bytes, formatted. Plot. Preceding the plot, there are five records.

- (1) first 80 characters of the title
- (2) remainder of the title
- (3) number of data points and total weight
- (4) size of counting circle
- (5) contour interval and characters.

The plot consists of 49 lines, each having 82 characters of which the first is carriage control. <u>Unit 9 - line printer</u> - record length: 127 bytes, formatted. Title of each sample. On this unit the program writes the number of data points and the title for each sample as it is read.

# Variables

ICODEl	overprinting flag

# DEFINITION OF DOMAINS AND CHARACTERIZATION

OF DOMAIN SUBFABRICS

72. In the final stage, the geologist uses the map displays produced in Stage 3 to combine groups into tentative domains (Fig 29).

73. Stage 4a. The information in the group data file is read by program INPT1 and stored for input to program HOMO. This program may be instructed to perform tests for homogeneity of means and dispersions on any given set of adjacent groups. If the hypothesis of homogeneity is not rejected, the area is increased in size by including neighbouring groups and the tests repeated. The area is thus expanded to the point at which the inclusion of any more groups result in the rejection of homogeneity in either dispersions or means. The program is then instructed to output the numbers of the groups within the area, which is at this point a subfabric domain. The procedure is then repeated to define other domains.

74. Stage 4b. Program DDKY1 merges the datafile keys for the groups within each domain into a single key for the domain. This key is in turn used by program INPK1 to retrieve from the data file the observations in the domain. Program WNST5 characterizes the domain subfabric for the fabric element being analyzed.

75. If displays of the data within each domain are required, they can be produced by repeating

Fig 29 - Stage 4 - Definiton of domains and characterization of domain subfabrics

Stage 3 with the following changes. In Stage 3a (Fig 29) program INPT1 is replaced by program INPK1 and the eigenvectors for the whole data file are replaced by the eigenvectors for the domain produced by program WNST5 in Stage 4b. Then using the group data file with the group numbers in the domain as written by program HOMO, it will produce displays of the group means within the domain. Alternatively, using the data file and domain key created by program DDKY will produce displays of the individual observations within the domain.

#### PROGRAM HOMO

76. This is an interactive program for testing grouped orientation data for homogeneity of concentration parameters and group means. The program first reads the group data, then accepts commands from the input device attached to I/O unit 5, normally an interactive terminal but possibly a card reader. In response to these commands, the program will add groups to or delete groups from the set of currently included groups and test for homogeneity of concentration parameters or for homogeneity of mean directions among the currently included groups. A flow diagram is shown in Fig 30(a) to (e).

#### Solution

77. The tests for homogeneity of concentration parameters and homogeneity of group mean directions are taken from Mardia, K.V., 1972, Statistics of Directional Data, London & New York, Academic Press, pp 267-271, with the following change: The number of degrees of freedom for the Chi-square statistics used for testing the concentration parameters has been taken as n-1, where n is the number of groups tested, instead of 2n-2 as given by Mardia. Checks performed using data generated artificially from a Fisher distribution with k=50 indicate that the correct number of degrees of freedom is approximately n-1.

#### Capabilities

78. Maximum number of groups is 100.

#### <u>Options</u>

79. Details of the commands and their effects

follow. These commands are entered on cards as unit 5 input.

- Name: Delete.
- Form: "D" followed by optional list of group numbers.
- Effect: If group numbers are given, those group numbers are deleted from the list of currently included groups. If no group numbers are given, all groups are deleted from the list.

Name: Restore.

- Form: "R" followed by optional list of group numbers.
- Effect: If group numbers are given, those group numbers are added to the list of currently

Fig 30(b) - Flow diagram for program HOMO - Part 2

Fig 30(c) - Flow diagram for program HOMO - Part 3

Fig 30(d) - Flow diagram for program HOMO - Part 4

included groups. If no group numbers are given, all groups are added to the list. List.

Name: Lis

Form: "L".

- Effect: Those group numbers in the list of currently included groups are printed. Those group numbers not in the list are printed separately.
- Name: Concentration Parameter Test.
- Form: "K".

Fig 30(e) - Flow diagram for program HOMO - Part 5

Effect: Concentration parameters of currently included groups are tested for homogeneity by the subroutine TCPF and the results of the test are printed.

Name: Mean Direction Test.

Form: "M".

Effect: Mean direction of currently included groups are tested for homogeneity by the subroutine TMDF and the results of the test are printed. Name: Automatic Deletion of Groups until Means are Homogeneous.

```
Form: "A"
```

Effect: The group whose mean direction is farthest away from the overall mean direction is deleted from the list of currently included groups. The mean directions of the groups then remaining in the list are tested for homogeneity. If the test indicates that the means are homogeneous, a message to that effect is printed and the command list is executed before returning to command mode. If the test indicates that the means are not homogeneous, the procedure is repeated, a new overall mean direction being computed first. This iteration is continued until either the become homogeneous or only two means groups remain.

Name: Stop.

Form: "S".

Effect: The program requests and reads a name for the set of currently included groups. This set of group numbers is then written on I/O unit 7 and the group stops.

#### Input

<u>Unit 1 - tape or disk</u> - record length: 3608 bytes, unformatted. Group data. As written by program INPT1 or INPK1.

<u>Unit 2 - card reader</u> - record length: 80 bytes, formatted. Predefined set of group numbers (optional). If this input is supplied, the format must be written by GRPS. The group number is the first variable of the GRPS output. See GRPS. If this is not supplied, an end-of-file (7/8/9) should be placed in the file.

<u>Unit 5 - card reader</u> - record length: 61 bytes, formatted. Commands. The commands are described under program options. The general format of the commands is:

Columns	Contents	
1	code letter	
2-5	first group number	
6-9	second group number	

78-81

.

.

twentieth group number

# <u>Output</u>

<u>Unit 6 - printer</u> - record length: 121 bytes, formatted. Messages and test results. These should be self-explanatory.

<u>Unit 7 - card punch or disk</u> - record length, 80 bytes, formatted. Final set of group numbers. Used as input by DDKY. These are in the same format as those produced by GRPS.

#### Subroutines

#### XKF

- estimates the concentration parameter for Fisher's distribution, given as R = Q/S, where Q = length of the resultant of a set of vectors, and S = the sume of the lengths of the vectors. The table given by MARDIA (1972, p322) is used to obtain AK if R is less than 0.9. Otherwise the estimate (1-2/N) (1-R) is used. The function TAB1 is used. Calling sequence: CALL XRF(R,N,AK,IE)
- R = proportional length resultant = Q/S
- N = number of vectors in the data
- AK ≈ estimated concentration parameter returned by this routine
- IE = error code returned.
  - = 0 if there is no error
  - = 1 if R is the outside range of 0 to 1. AK
    is set to 0.0.

#### PROGRAM DDKY

80. The program reads sets of integers and constructs a new one containing all the integers in all sets read. Not all the sets in the input file are used. Which are used is determined by sequence numbers read from another I/O unit. A flow diagram is given in Fig 31.

#### Solution

81. The integers in the input sets are copied sequentially into the output set as they are read. After all the input sets have been copied, the integers in the output set are ordered by calling the subroutine ORDERH. The program does not check for duplicates. An integer will appear in the output set as many times as it appears in all of the input sets.

#### Capabilities

82. Maximum number of input sets to be included is 100. Maximum size of each input set is 20 integers. Maximum size of the output set is 1000 integers.

# Input

<u>Unit 1 - tape or disk or Card reader</u> - record length: 80 bytes, formatted. Input sets. This is the output from HOMO.

<u>Unit 2 - card reader</u> - record length: 80 bytes, formatted. Numbers of those input sets to be used. Same format as for unit 1, see format for

HOMO and GRPS.

#### Output

Unit 7 - tape, disk or card punch - record length:

<u>Input Files</u> Group data file. Unit l input to INPT1.
