NATIONAL ACCOUNTS INCOME AND EXPENDITURE

BY QUARTERS

1947-61

Published by Authority of
The Honourable George Hees, Minister of Trade and Commerce

FOREWORD

Quarterly estimates of Gross National Product and related aggregates were first published by the Dominion Bureau of Statistics in the fall of 1953 with the report, National Accounts, Income and Expenditure, by Quarters, 1947-1952. Since that time, they have been prepared regularly each quarter, with a time lag of slightly more than 2½ months. A consolidated report was published in 1959 covering the period 1947 to 1957 and presented figures on the same basis as the revised annual data published in National Accounts, Income and Expenditure, 1926-1956. The present report brings together, for the convience of users, the series for the years 1947 to 1961 comparable to those published in the 1947-1957 volume, as well as incorporating a number of tables covering government revenue and expenditure, national saving, and seasonally adjusted constant dollar estimates of Gross National Expenditure, which have been developed recently.

The preparation of National Accounts estimates on a quarterly basis is inherently a more complex task than the estimation of their annual counterpart. In particular, problems of timing and consistency become more acute when dealing with quarterly estimates, and for this reason, the quarterly data should be regarded as having a somewhat lower order of accuracy than the annual figures. Moreover, the procedures employed in seasonally adjusting economic time series are based on an averaging technique, and thus contain an element of approximation. In spite of this, the statistics are believed to reflect in broad outline the main contours of quarter-to-quarter movements in economic activity, and the shifting pattern of income and expenditure over the span of the business cycle.

The present report is divided into two parts. Part I presents the tabular information in both unadjusted and seasonally adjusted form. Part II reviews the sources and methods upon which the quarterly estimates rest, and is designed to give users of the data a general background for appraising the reliability of the material. This section also includes notes on the conceptual framework which underlies the quarterly estimates. No analysis of the statistics is given in this report.

The present volume was prepared by the National Accounts and Balance of Payments Division of the Bureau. In a broad sense, a number of Bureau Divisions have contributed to this report. The estimates of wages, salaries, and supplementary labour income are prepared in the Labour Division of the Bureau; most of the price series used in the deflation project are prepared in the Prices Division; net income of farm operators from farming operations in the Agriculture Division; and exports and imports of goods in the External Trade Division. The basic data for many of the estimates are collected and tabulated in the Industry and Merchandising Division, the Public Finance and Transportation Division, the Business Finance Division, and the Special Surveys Division. The housing data are provided by Central Mortgage and Housing Corporation. The assistance of cooperating firms and governments is gratefully acknowledged.

WALTER E. DUFFETT,

Dominion Statistician.

Includes capital expenditures by private and government business enterprises, private non-commercial institutions, and outlays on new residential construction by individuals and business investors.

4 The book value of inventories is deflated to remove the effect of price changes and the derived "physical" change is then valued at average prices of the current period to obtain the value of physical change. The difference between this value of physical change in book value is called the inventory valuation adjustment. (See line 8, Table 1).

2.4	operators	32, 976	33, 512	33, 804	34, 372	33, 666

¹ See footnote 1, Table 1.
² Includes an arbitrary smoothing of crop production and standard seasonal adjustments for withdrawals of grain from farm stocks and the change in livestock items. Because of the arbitrary element, too precise an interpretation should not be given the seasonally adjusted figures of accrued net income of farm operators.

See footnote 3, Table 2.
In the seasonally adjusted series, the value of grain crop production in each quarter is taken as one-fourth of the estimated value of crop production for the year as a whole (see footnote 2, Table 10). All other items in the farm inventories series are seasonally adjusted by standard technically adjuste niques.

In these tables many of the series have had to be seasonally adjusted at a finer level of detail, giving rise to totals which differ somewhat from those previously published. Since it is not feasible at this time to revise data prior to 1957, an adjusting entry is necessary to reconcile the detail to previously published totals.

The quarterly figures of real property taxes unadjusted and seasonally adjusted are obtained by dividing annual totals by four since real property taxes accrue uniformly throughout the taxation year. Because in recent years, changes in real property tax rates have been generally upward, this treatment gives rise to fictitious seasonal between the fourth and first quarters in the seasonally adjusted indirect taxes series.

3 See footnote 1, Table 5.

¹ These implicit indexes are currently weighted price indexes. They reflect not only pure price changes, but also changing expenditure patterns within and between major groups. Quarter to quarter comparisons based on the seasonally adjusted data are less subject to the problem of shifting weights than are similar comparisons based on data unadjusted for seasonality, and therefore may be used as indicators of price change.

PART II

CONCEPTS, SOURCES AND METHODS

SECTION 1

REVIEW OF SOURCES AND METHODS, AND SUMMARY OF CONCEPTUAL FRAMEWORK

This section provides a general review of the statistical sources upon which the quarterly National Accounts estimates are based, together with a description of the procedures used in making the required estimates. It is designed to give the users of the data a general view of the content of the

various aggregates and background for appraising the reliability of the statistical results. The section is introduced by a note on concepts and definitions, and a discussion of problems peculiar to estimates of Gross National Product and Expenditure and supporting sector accounts.

CONCEPTS AND DEFINITIONS

Except for the time interval involved, the objectives of both the quarterly and annual estimates of Gross National Product and Expenditure are identical - that is to measure the value of goods and services produced by Canadian residents in a given period (a quarter or year) and to portray the interrelated structure of transactions generated by productive activity. The objectives of both the quarterly and annual estimates of personal income and expenditure are to measure all current receipts of income, in cash or in kind, by persons (including individuals, private non-commercial institutions and pension funds), and to show the disposition of this income by major categories. Thus, the broad conceptual framework which underlies the quarterly estimates is the same as that upon which the annual estimates are based. This conceptual system is described in Part II of National Accounts, Income and Expenditure, 1926-1956, and is not further elaborated here. However, for convenience, a brief description of the main aggregates is given below.

Gross National Product

An overall measure of economic achievement is provided by the Gross National Product. This aggregate measures the value of goods and services produced by Canadian residents in a given period by adding together all costs arising in production. For the economy as a whole, these costs consist first of factor costs, that is to say, the earnings of the factors of production employed: wages and salaries, corporation profits before taxes, rent, interest and miscellaneous investment income, accrued net income of farm operators from farm production, and net income of non-farm unincorporated business. The sum of these factor costs plus the inventory valuation adjustment is termed national income. To arrive at the total which measures production at market prices it is necessary to add elements of market prices which do not represent

incomes of factors of production, that is, capital consumption allowances and miscellaneous valuation adjustments, and indirect taxes less subsidies. The total thus obtained is called the Gross National Product.

Gross National Expenditure

The market value of goods and services produced by Canadian residents in a given period can also be measured by adding together all final sales made during the period, adjusted for changes in inventories and imports; for what is produced must be disposed of, either by sales or by addition to inventories. The aggregate arrived at in this manner is called Gross National Expenditure. It is made up of four main components: sales to consumers (personal expenditure on consumer goods and services); sales to governments (government expenditure on goods and services); sales to business on capital account (business gross fixed capital formation in new construction, machinery and equipment, and the value of physical change in inventories); and sales to non-residents (exports of goods and services). Since the total of sales thus enumerated includes the value of imported goods and services and since it is desired to measure production of Canadian residents only, imports of goods and services are deducted from the grand total of sales.

Personal Income

Personal income is a measure of all current receipts of income, in cash or in kind, of persons (including individuals, private non-commercial institutions and private pension funds). It differs from National Income in that it excludes all earnings not paid out to persons, such as undistributed corporation profits and profits of government business enterprises, and includes receipts which have not been

earned in the course of current production, that is, transfer payments. The whole of net income of unincorporated business is included since it is not statistically possible to separate withdrawals for personal use from earnings retained in the business.

Personal Expenditure

The other side of the personal income and expenditure account shows the disposition of personal income by three main categories: personal direct taxes, (i.e. personal income taxes, succession duties, and miscellaneous licenses and fees), personal purchases of goods and services; and personal net saving. The latter category is estimated residually, and includes, in addition to cash savings, purchases of bonds, the savings portion of life insurance premiums, repayment of debt including residential mortgages, and net new investment in plant, equipment and inventories by individual enterprisers including farmers.

Government Revenue and Expenditure

The tables on government revenue and expenditure bring together, under uniform headings, the activities of all governments in Canada on a quarterly basis. They are designed to include only those transactions which have relevance for the National Accounts and consequently the surpluses or deficits shown here differ from those shown in the conventional budgetary accounting statements issued by the various public authorities. For example, government expenditures are defined to exclude certain transactions such as those relating to reserves, write-offs, amortizations, and other similar items as well as the purchase of land and existing capital assets. On the other hand, they include the transactions of extra-budgetary funds, such as unemployment insurance, old age security, workmen's compensation, and government pension funds. Government loans and investments, and debt retirement are excluded.

On the revenue side, corporation taxes have been adjusted to an accrual basis, and investment income earned on extra-budgetary accounts is included with total revenue. For a fuller description of the government sector as defined for National Accounts purposes, see pages 126 to 129 of the reference document, National Accounts, Income and Expenditure, 1926-1956.

At the Federal level, the quarterly data are almost as reliable as the annual estimates published in the annual National Accounts reports, since the

figures are based primarily on official records of the Comptroller of the Treasury and on accounting statements of a number of other government agencies. At the provincial level, the main sources of data for current years are the quarterly returns submitted by nine of the provinces to DBS and are of a fairly high order of accuracy.

The quality of the municipal quarterly data is less satisfactory. The annual data are fairly accurate as they are obtained from published reports of the various provincial Departments of Municipal Affairs, and from a highly reliable survey of municipal governments for current years where provincial annual reports are not yet available. The major portion of municipal revenues is derived from real property taxes, and this figure is distributed in equal amounts to each quarter, Municipal expenditures on goods and services are allocated primarily on the quarterly distribution of provincial government expenditure on goods and services. Since the quarterly data at the municipal level are considerably weaker than for the other two levels of government, the municipal figures are not shown separately, but are combined in a total for both provincial and municipal governments.

National Saving - Source and Disposition

The total saving of Canadians is shown in this account. It is made up of personal net saving, government saving as reflected by the government surplus or deficit, and business gross saving in the form of undistributed corporation profits, capital consumption allowances and the accrued earnings of farmers arising out of the operation of the Canadian Wheat Board, An inventory valuation adjustment is made to eliminate unrealized gains or losses resulting from price changes from goods held in stocks. The national saving estimates contain an element of non-resident saving in the undistributed profits of corporations accruing to non-residents. Conceptually this should be removed but for statistical reasons no adjustments have been made.

The disposition of national saving is reflected in the outlays on residential and non-residential construction, machinery and equipment and inventories. The surplus or deficit on current account with non-residents reflects, in the case of a surplus, that a portion of saving by Canadians has been made available for use in other countries, whereas a deficit indicates that non-resident saving has made a net contribution to the resources available to Canadians.

PROBLEMS RELATING TO THE CONCEPT OF QUARTERLY ESTIMATES

Although the concepts and definitions which underlie the annual estimates are theoretically consistent with the requirements of the quarterly esti-

mates, a number of special problems of application arise when an attempt is made to convert this conceptual system to a quarterly basis. It will be appropriate at this point to comment briefly on some of these problems,

¹ Except for the allowance which is made for the adjustment on grain transactions (see p. 86).

(a) The Accrual Principle

Quarterly estimates of Gross National Product and Expenditure aim primarily at measuring the value of production in specific quarters. As indicated above, this can be achieved in two ways—by summing the costs involved in production, on the one hand (G.N.P.), and by tracing the disposition of production through sales adjusted for imports and changes in inventories, on the other hand (G.N.E.). To arrive at Gross National Product, it is theoretically desirable to include expenses on an accrual basis in order to relate factor and other costs to the quarter in which the economic activity occurred. For example, bond interest which is normally paid only once or twice a year, accrues continuously throughout the year, and is, therefore, chargeable to the production of all four quarters.

In practice, however, the factor and other costs included in Gross National Product are drawn from a variety of different sources which are, in many cases, independent of each other in an accounting sense. For example, quarterly corporation profits (and in some cases, net incomes of unincorporated businesses) reflect prevailing practices in industry with respect to the treatment of business expenses (mainly accrual), while the bulk of wages and salaries, and indirect taxes, are reported to the Bureau on a cash basis. It will therefore be seen that there is necessarily a mixture of both cash and accrual elements in the quarterly estimates of Gross National Product. In general, the principle of computing expenses on an accrual basis has been adhered to wherever the data permit it to be done, Even within these limits, however, consistency with other series has had to be an over-riding consideration.

From the foregoing it will be clear that failure to apply the accrual principle uniformly throughout the estimates of Gross National Product stems mainly from the manner in which data are reported to the Dominion Bureau of Statistics. However, comparibility in the estimates from quarter to quarter need not be affected, even though a degree of unbalance between the Gross National Product and Gross National Expenditure may exist within each quarter, because individual series are not mutually consistent in an accounting sense. This unbalance is reflected, together with other errors and omissions, in the item called "residual error of estimate". It will be noted that the latter is small relative to the magnitude of the aggregates included in the tables.

To some extent the problem of the "accrual" versus the "cash" basis of calculation applies to annual estimates as well. However, since the year rather than the quarter is regarded as the standard unit of time for production and accounting purposes, cash payments and accrued expenses coincide to a very large extent over the full year.

In contrast to the Gross National Product which is linked to the accrual principle through the "measurement of production" approach, personal income is defined in terms of "receipts" of income. Thus, in general, the quarterly components of personal income are shown on a "receipts" basis

except in the case of certain elements of interest and net rental income of persons where the statistical information permits only an accrual method of calculation. In the case of net income of unincorporated business, it is not possible to separate withdrawals for personal use from earnings retained in the business. This latter problem is not unique to the quarterly estimates, however, but also occurs in the annual calculations.

(b) Quarterly Farm Inventories²

The measurement of farm inventories (and thus of net income of farm operators from farm production) on a quarterly basis presents a difficult theoretical problem which is closely related to the accrual principle discussed above. Farm production has marked seasonal characteristics associated particularly with plant growth, and in such cases it is difficult to assess the production represented by growing inventories not yet in market form. Thus, the harvesting of a grain crop in the fall of the year represents the culmination of the productive activity of previous periods, and in a theoretical sense the value of this production might be "accrued" throughout the ploughing, seeding and growing periods. As a practical matter, however, it is impossible to assess the value of growing inventories in this way; such a procedure would entail a forecast of the farm price value of the harvested crop, thus implying a knowledge of future climatic conditions and prices which cannot be foreseen.

In the case of "goods in process" in manufacturing, we can obtain a reliable measure of production by evaluating "inputs"; thus in the broadest sense, non-farm inventories of "goods in process" appearing in Gross National Expenditure are evaluated at cost, being matched on the Gross National Product side of the accounts by factor shares and other costs. Theoretically, it would be desirable to carry over this procedure to the treatment of agricultural inventories. A considerable part of agricultural activity takes place in the first half of the year, and it should be the objective to measure the value of "inputs", or factor shares and other costs generated in these periods. This approach does not imply any attempt to place a value on crops growing in the field, but is simply a recognition of the fact that unless inventories are measured on an "input" basis, Gross National Product is understated in the first half of the year by the amount of factor and other costs chargeable to the production of this period, and overstated in the third (harvest) quarter by an equivalent amount. Thus, to take account of grain inventories only in the third (harvest) quarter could conceivably result in farm net income showing losses in the early part of the year, with net income in the third quarter greater than for the year as a whole. On the other hand, the "input" method would eliminate such losses in the early part of the year, and reduce the amount of net income in the third quarter by whatever expenses are incurred in the early part of the year.

² For method of estimation, see page 86.

At the present time, statistics are not available which will permit the quarterly allocation of farm expenses to grain inventories on an "input" basis, and as a consequence grain inventories have to be counted as production only when they reach marketable form, that is, after harvesting. Consequently, the level of Gross National Product in the first half of the year does not vary according to the intensity of crop-production activity; the value of production generated by such activity is offset by the expenses charged against gross farm income, there being no counter-balancing increase in grain inventories. In the third quarter, however, accrued net farm income (and thus Gross National Product)

is overstated to the extent that the expenses incurred earlier in the year are not charged against the harvested crop at this particular point of time. The method of estimating changes in grain and livestock inventories are described on page 87.

The concentration of crop production in the third quarter of the year presents a special problem of seasonal adjustment which cannot be adequately handled by standard techniques. The treatment accorded this item is the seasonally adjusted data is described on page 98, under section 2, "Seasonally Adjusted National Accounts Data".

SOURCES AND METHODS

GROSS NATIONAL PRODUCT

The following outline of sources and methods gives a brief summary of the content of each component and describes the procedures employed in making the required estimates. The section is designed to permit users of the data to appraise in a general way the reliability of the statistical results.

Wages, Salaries, and Supplementary Labour Income

The estimates of wages, salaries, and supplementary labour income are prepared by the Labour Division of the Dominion Bureau of Statistics. These estimates are designed to include all compensation to Canadian wage earners and salaried employees, including income in kind such as board and lodging.3 They do not include the earnings of selfemployed individuals or partners, the income of independent professionals, the net income of farmers, or payments to members of the armed services. Wages and salaries are estimated on a "gross" basis - that is, they are reckoned before tax deductions, contributions of employees to unemployment insurance, pension and other social security schemes. Retroactive wage increases are included in the quarter in which they are paid.

Supplementary labour income consists of other expenditures by employers on labour account that can be regarded as payment for employees' services. Included here are employers' contributions to pension and employee welfare funds, the unemployment insurance fund, and workmen's compensation funds.

Monthly estimates are prepared for each industry in each province. The general method is to distribute the estimated annual totals on the basis of related monthly indicators. In a recent year, for which no independent total is yet available, the preliminary estimates are obtained by using the monthly indicators to project from the monthly data of the last year for which such a total is available. Quarterly estimates are obtained by summing the three relevant monthly estimates.

The greater part of the monthly income estimates is based on projections using monthly payroll indexes. For industries in which there is no monthly payroll coverage, as in agriculture and some of the service groups, special indexes are constructed from directly related information. In a few cases estimates are based on indirect evidence, but these are quantitatively unimportant in the aggregate.

(a) Industries Covered by Payroll Indexes

Payroll indexes, calculated from reports of establishments normally employing fifteen or more persons, are used to estimate for the following industries: manufacturing; forestry; construction; mining; public utilities; transportation, communication and storage; trade; personal service, recreation service, and business service; finance, insurance, and real estate. Federal and provincial government payments are estimated on the basis of indexes which are constructed from the monthly returns of wages and salaries as received by the Public Finance and Transportation Division of the Dominion Bureau of Statistics.

(b) Industries Estimated on the Basis of Related Data

Wages and salaries in agriculture are estimated by means of an index obtained by multiplying numbers of paid workers (from the DBS Labour Force Survey) by a farm wage-rate index.⁵ Monthly wage and salary figures for community service and for municipal government are derived by employing

It may be noted that income in kind consumed by farm proprietors is included with accrued net income of farm operators from farm production, while food and clothing supplied to the armed forces is included with military pay and allowances.

That portion of employers' contributions to work-men's compensation funds which is estimated to be for medical aid and hospitalization is not regarded as a form of employee income and is therefore excluded.

⁵ This index is based on a survey made only three times each year. Inter-survey period indexes are derived by interpolation or extrapolation.

indexes obtained by multiplying numbers of paid workers in each industry by average weekly earnings in finance, insurance, and real estate. Similar techniques are employed to estimate the value of income in kind received by employees of hospitals and religious institutions.

(c) Estimates Based on Indirect Evidence

Total wages and salaries paid in the fishing industry are estimated using an index of the monthly value of fish caught and landed.

In hunting and trapping, the annual figure is arbitrarily divided into six equal parts covering the six coldest months of the year.

(d) Supplementary Labour Income

Employers' contributions to pension and welfare funds on behalf of employees are estimated on the basis of trends observed in the annual estimates of these items. It should be noted that pensions paid by employers who had no funds set aside for that purpose and to which employees do not contribute are also included as supplementary labour income.

Employers' contributions to unemployment insurance and to workmen's compensation funds are estimated on the basis of the trend of total wages and salaries, excluding agriculture and personal service.

Military Pay and Allowances

Payments to members of the armed forces in Canada and overseas are treated as compensation is services rendered. Under this heading are included military pay of rank and trades pay, marriage, separation, and subsistence allowances, clothing allowances, and the rehabilitation and civilian clothing grants payable to members of the Special Forces on discharge. War service gratuities and all post discharge re-establishment benefits are excluded as transfer payments. The estimated value of food and clothing issues "in kind" is included.

Cash pay and allowances to the armed forces are available on a monthly basis from the Department of National Defence.

Income in kind is calculated on the basis of quarterly statements of strengths of the three armed services, and estimated man-day costs for food and clothing.

Corporation Profits Before Taxes

Corporation profits are measured before the deduction of corporation income and other direct taxes. Since the estimate is required on a national hasis, it includes the earnings of Canadian factors

only, and dividends and profits remitted to nonresidents are deducted. Undistributed profits relating to assets owned by non-residents should also be deducted, but because of statistical difficulties this has not been done. Since the National Income includes only earnings from the production of new goods and services, capital gains and losses are excluded.

The general procedure followed in estimating quarterly corporation profits before taxes is similar to that employed for the annual National Accounts estimates.

The concept "profits before taxes" used in the National Accounts differs somewhat from the one employed by the Department of National Revenue for taxation purposes. Adjustments are made to the calendar year figures published by the Department of National Revenue in order to bring them into line with the definitions required for the National Accounts. Depletion charges, which are deductible for income tax purposes, are added back, since discoveries of natural resources are not counted as part of capital formation; the exhaustion of natural resources therefore is not regarded as a charge against the national income. Another adjustment is for provincial mining and logging taxes which are allowed as an expense for income tax purposes, but are added back to profits in the National Accounts. Similarly, banks calculate profits for taxation purposes after transfers to reserves. These transfers are added back to the national income since they are not a charge against production, and a deduction is then made for estimated bad debt losses. Charitable contributions made by corporations are added back on the grounds that they are not a cost of production, but a distribution of earnings. Corporate losses are also deducted in order to bring the figures to a profits less losses basis. It should be noted that under income tax regulations, taxable profits, calculated before payment of dividends, do not include dividends received from Canadian corporations. No special adjustment need therefore be made to eliminate Canadian intercorporate dividends. Non-taxable foreign dividends received by corporations are added to profits. The profits of co-operatives are included in the National Accounts in corporation profits.

From 1950 on, the basic annual data have been distributed according to movement of profits published in *Corporation Profits* (Business Finance Division, DBS) containing the results of a quarterly sample survey of corporations. Dividends and profits remitted to non-residents quarterly are supplied by the Balance of Payments Section of DBS.

Prior to 1950, the average quarterly pattern for the years 1950-1956 was employed to distribute annual profits by quarters.

Quarterly corporation profits from the above publication form the basis of current quarterly estimates.

Rent, Interest, and Miscellaneous Investment Income

This component of national income includes interest, net rental income and miscellaneous investment income of persons, government investment income, and withholding taxes on investment income such as interest, dividends, rents and royalties paid to non-residents. All these components are measured before deduction of direct taxes, and include the earnings of Canadian factors only. All interest on the public debt and a part of interest on the consumer debt are treated as transfer payments and are therefore excluded.

(a) Interest, Net Rents and Miscellaneous Investment Income of Persons

This component is made up of the following items:

- (i) Canadian bond, mortgage, and deposit interest received by or accruing to persons;
- (ii) Net rents received by or accruing to persons;
- (iii) Interest and dividends received by persons from non-residents;
- (iv) Miscellaneous investment income.

(i) Canadian bond, mortgage and deposit interest

The annual estimate of bond interest received by persons is distributed by quarters on the total of interest on government direct debt, CNR guaranteed and non-guaranteed debt, funded corporate debt. less the total interest paid to non-residents. The interest on the federal debt quarterly is obtained from the Comptroller of the Treasury, Quarterly data on provincial interest payments are available since 1951; for previous years, the pattern of interest payments prevailing in 1951 was employed. Quarterly estimates of corporate debt outstanding (to which a rate of interest is applied), Canadian National Railway guaranteed and non-guaranteed debt interest and corporate funded debt interest are all provided by the Bank of Canada. Quarterly interest paid to non-residents is estimated by the Balance of Payments Section of DBS.

The figure of mortgage interest accruing to persons (including interest on agreements of sale) is derived by straight line interpolations between the annual totals. Currently, the annual interest is forecast and the quarterly estimates are obtained by interpolation. Deposit interest received by persons from the chartered banks is obtained from the Bank of Canada, Imputed bank interest to individuals is estimated according to the number of cheques cashed as compiled by the Business Finance Division, DBS. Other deposit interest received is moved on a straight line.

(ii) Net rents received by persons

For convenience in making the estimates, the rental field is divided into three main parts:

- (a) Residential non-farm rents-
 - (i) Net rents paid by tenants.
 - (ii) Net rents imputed on owner-occupied dwellings.
- (b) Non-residential non-farm rents, and
- (c) Residential and non-residential farm rents.

Of these three major classes, the first is the most important in size and is also the one for which statistical coverage is most satisfactory.

Broadly speaking, the method used for each class is similar; total gross rents are first estimated and total expenses subtracted. Net rents paid to other than persons are then deducted leaving net rents received by individuals. The sum of net rents received by persons for the above three groups gives the required total.

Residential non-farm rents. - Gross residential non-farm contract rent paid by tenants is estimated by multiplying the number of tenant-occupied dwellings by the figure of average rent per dwelling. From this gross figure of contract rent, the cost of facilities provided by the landlord such as heat, water, electricity, amortization of stoves, refrigerators, etc., is deducted to arrive at gross space rent paid by tenants. Gross space rent imputed on owneroccupied dwellings is derived by multiplying the number of owner-occupied dwellings by an average imputed space rent per dwelling. Space expenses which include repair and maintenance, municipal residential property taxes, depreciation, fire insurance, mortgage interest and real estate commissions on transfers of existing dwellings, are then deducted from the total of gross paid and imputed space rent leaving paid and imputed net rent paid by individuals as a remainder. Net rent paid to other than persons is deducted and an estimated rental for garages is added. This leaves the portion of paid and imputed net rent which is received by individuals.

Quarterly figures of the number of non-farm tenant and owner occupied dwellings are interpolated between the annual benchmarks on the basis of dwellings completed. Currently the figures are brought forward on the basis of dwelling completions obtained from New Residential Construction published by the Special Surveys Division of the DBS. The average rent paid by tenants is obtained monthly from the Prices Division of DBS.

Landlords' heating costs are projected on the figures of residential fuel consumption. The other facility expenses are interpolated between the annual benchmarks. Currently, quarterly figures are estimated on the basis of the past trend.

Imputed space rent on owner-occupied dwellings is calculated by multiplying the average space rent paid by tenants by a ratio of the number of rooms in owner-occupied to tenant-occupied dwellings. Average space rent paid by tenants was obtained by deducting the cost of facilities provided by the landlord from the contract rent paid by the tenant.

The estimates of repair and maintenance, depreciation, and mortgage interest are based on data obtained from C.M.H.C. Taxes are an equal quarterly allocation of the annual figure.

From 1947 to 1954 the estimates of fire insurance and real estate commissions on the transfer of existing dwellings are interpolations between annual benchmarks. Net rents paid by individuals to corporations, government, C.M.H.C. and abroad are related to the pattern of net rents paid. From 1955 on, annual ratios of net to gross rents received by persons are interpolated and applied to the gross space rent paid and imputed to estimate quarterly net rental income of persons. Garage rent, not implicitly included in house rent, is estimated by multiplying the number of garages by an estimated average garage rent.

Non-residential, non-farm rents received by persons are estimated quarterly by straight line interpolation.

Residential and non-residential farm rents are estimated for the quarter by a straight line projection between annual benchmarks.

(iii) Interest and dividends received by persons from non-residents

Quarterly estimates of interest and dividends received by persons from non-residents are supplied by the Balance of Payments Section of the Bureau.

(iv) Miscellaneous investment income

In addition to investment income received by life insurance on behalf of Canadian policy-holders, this component includes several categories of income. These are: investment income of fraternal and mutual benefit societies, which like life insurance companies, are treated as individuals; interest on federal government annuities and private industrial pension funds, royalties and the profits of mutual non-life insurance companies.

The investment income of life insurance companies, fraternal and mutual benefit societies, and industrial pension funds is divided into two parts—interest received from government bonds, and other. The government debt interest received is projected by quarters on the total payments of government direct debt interest paid.

Investment income arising from other sources is interpolated as a straight line.

Investment income on federal government annuities account is distributed according to the interest paid on the federal debt.

Other income is simply the annual estimate divided by four.

(b) Government Investment Income

This item includes profits of government business enterprises, and interest on government loans and advances, and on public funds.

Profits of government business enterprises consist of profits, net of losses, of those government agencies which conduct their activities on an essentially commercial basis, setting a price for their services which is calculated to cover costs. Included here are profits of the Canadian National Railways, provincial liquor control boards, and provincial and municipal public utilities such as hydroelectric systems, telephone systems, street railways, and so on. The federal Post Office Department is included here, its gross expenditures being offset against its gross revenues to arrive at an estimate of profits. Net imputed rent on government buildings is also included here.

At the federal level, current quarterly data on the profits (or losses) of the majority of the federal government business enterprises, such as the Post Office, Canadian National Railways, St. Lawrence Seaway Authority, Polymer Corporation Limited, Eldorado Mining and Refining, are now available. Where quarterly information could not be obtained the figures are based on the previous year's annual and allocated equally to the four quarters of the current year. These are adjusted retrospectively when firm annual figures became available from the published annual reports of the enterprises.

At the provincial level, quarterly profits of liquor commissions are available for some provinces, while for others annual data are distributed on the basis of quarterly provincial sales of liquor, wine and beer. Profits of hydro-electric commissions are allocated in accordance with average consumption of electric power. Profits of provincial telephone and railway companies and other miscellaneous enterprises are allocated equally among the four quarters of the year. Current period estimates are based on the distribution of a forecast annual figure, based on budget estimates and other data.

At the municipal level, all profits of public utilities are distributed by straight line interpolation between annual figures. For current quarters, this procedure involves a forecast of the current annual figure.

Interest on government loans, advances and investments includes interest on loans to government agencies such as The Canadian National Railways and various public utilities, and to foreign and domestic governments. At the federal level the interest on foreign loans is available quarterly; the remaining data are estimated annually from the latest federal public accounts and distributed evenly over the four quarters of the current year. Provincially, quarterly estimates of interest earned on

⁶ Only rents paid are included here. Imputed rents of owner-occupied premises used by business are implicitly included in the estimates of profits and net income.

⁷ This treatment is approximate only since no allowance has been made for depreciation on postal property.

loans to various government agencies and utilities are available from the financial returns supplied quarterly by the various provinces. At the municipal level, an annual estimate is made by applying an annual average interest rate supplied by the Bank of Canada, to a figure of public utility and guaranteed debt of the municipalities; the quarterly figures are derived by straight line interpolation between annual data, involving a forecast annual for the current period.

Interest on government—held public funds includes interest on government pension and superannuation funds, social insurance, sinking funds, the unemployment insurance fund, and provincial workmen's compensation funds. The Unemployment Insurance Commission supplies the quarterly figures of interest received on their investments, but the interest receipts of the other funds are distributed quarterly according to the movement of gross debt interest. Again, for current quarters, this procedure involves a forecast of the annual total for the current year.

(c) Adjustments

The estimates of corporation profits, bond interest and miscellaneous investment income described thus far include interest on the public debt and the "transfer" portion of interest on consumer debt. These transfers must be excluded from the National Income. Further, the estimates of dividends and interest paid to non-residents, which have been explicitly excluded from these totals, include a portion retained by the federal government in the form of "withholding taxes"; as these withholding taxes are retained in Canada it is therefore necessary to add them back.

Interest on the public debt. The federal content of this item, on a "due date" basis is obtained quarterly from the Comptroller of the Treasury. At the provincial level quarterly data of interest payments are also available since 1951, while for previous years, the pattern of interest payments prevailing in 1951 was employed. The municipal content is distributed on the basis of studies of bond and Treasury bills outstanding. Again for current quarters, a forecast of the annual is involved.

Interest on consumer debt is calculated by applying a rate of interest to the estimated volume of consumer credit outstanding at the end of each quarter. These data are obtained from the Statistical Summary published by the Bank of Canada.

Withholding tax collections on interest, dividends, etc., paid to non-residents are available quarterly from the Comptroller of the Treasury.

Accrued Net Income of Farm Operators from Farm Production

Accrued net income of farm operators from farm production and net income of non-farm unincorporated business are accounted for separately in national income, since they represent a mixture of labour and investment income which cannot be separated on anything but an arbitrary basis.

The quarterly estimates of accrued net income of farm operators from farm production are computed in the same way as the annual estimates, that is, by constructing a synthetic operating account for the agriculture industry. The procedure is summarized briefly below: farm cash income from the sale of farm products is available on a quarterly basis from the Agriculture Division of DBS. Quarterly estimates are made of the value, at farm prices, of land and forest products grown and consumed on farms, and these, together with imputed gross rents on owner-occupied farm dwellings constitute the value of income in kind received by farmers, The value of the physical change in inventories of grain and livestock held on farms is computed at prevailing quarterly prices. The sum of all these items constitutes gross farm income.

Farm operating expenses are deducted from this figure. These include taxes on real estate, gross rents on farm land, labour costs, interest on farm debt, feed and seed, binder twine, repairs and depreciation, operating costs of farm machinery, fertilizer, and so on. The resultant figure, after deduction of these expenses, corresponds closely to the annual concept of "net income of farm operators from farming operations" as published by the Agriculture Division of DBS.

For National Accounts purposes, certain adjustments are made to this figure. Imputed rents on owner-occupied farm dwellings and profits of agricultural enterprises organized as corporations are deducted, since these are included in investment income. An adjustment on grain transactions is then made in two parts. The first part is an estimate of the undistributed earnings of the Canadian Wheat Board, and the second allows for the fact that the earnings of the Canadian Wheat Board are calculated on the basis of change in the book values of inventories, whereas the value of physical change is required for the National Accounts. The resulting figure reflects the earnings of farm operators from current production, which is the appropriate aggregate for inclusion in the Gross National Product.

⁶ Data obtained from weekly reports on Canadian Grain Statistics.

To obtain the quarterly distribution of the above items, a number of special procedures have had to be adopted. Farm cash income is available quarterly from the Agriculture Division of DBS. Estimates are made for each of the items of income in kind consumed on farms, and these are then summed to obtain a total quarterly figure; when necessary, the four quarters are adjusted to bring them into line with the final annual estimate. Specifically, the value of dairy products consumed on farms in each quarter is calculated from monthly price and quantity data supplied by the Agriculture Division of DBS. Estimates of the quantity and value of poultry consumed on farms are also supplied by the Agriculture Division. Consumption of hens and chickens is allocated throughout the year, while other types of poultry consumed are assigned arbitrarily to the fourth quarter, The value of eggs consumed on farms is published monthly by the Agriculture Division. Estimates of the value of cattle, calves, sheep, lambs and hogs killed and eaten on farms are computed from number and price data. Numbers are available for each six-month period from the semi-annual livestock surveys of the Agriculture Division, and these are arbitrarily allocated to the periods in which farm slaughterings normally occur, that is, to the first and fourth quarters; for current periods a forecast is made until the livestock survey is available. Current prices per head of livestock are obtained by projecting the average price per head according to the 1941 Census, on an index of prices per hundredweight.

The annual estimate of fruits and vegetables consumed in kind is distributed quarterly according to production patterns for each area worked out by the Agriculture Division. For current periods, this method involves a forecast of the annual figure. The value of forest products consumed on the farm is assigned to the months of October to April, inclusive.

Quarterly changes in farm inventories are calculated as follows: the Agriculture Division of DBS prepares estimates of stocks of grain held on farms at the end of each quarterly period, The quarterly quantum change is then valued at the average farm price prevailing during the quarter. Similarly, estimates of the number of head of livestock on farms, by type and age group, are prepared quarterly by the Agriculture Division. The quarterly quantum changes in the case of livestock are valued at farm prices prevailing at the end of each quarter.

Quarterly farm operating expenses are obtained by allocation of the annual estimate. The method of allocation differs for most of the expense items. Taxes on real estate and gross rents on farm lands are distributed equally to the four quarters of the year. Farm labour costs are estimated monthly by the Labour Division of the Bureau. Interest on farm debt is computed by straight line interpolation between annual benchmarks. The bulk of feed and

seed expense is allocated to the first and fourth quarters of the year, since grain fed to livestock is heaviest during the winter period.

Machinery repair is allocated equally to the first three quarters of the year, while building repair is determined by straight line interpolation between annual estimates. Depreciation is also determined by straight line interpolation. The bulk of tractor fuel expense is allocated to the second and third quarters. Expenses on truck tires, tubes, licence fees, petrol, oil, lubricants, repairs and insurance are allocated on a pattern of expenditures obtained from the Agriculture Division, DBS. Estimates of fertilizer are allocated evenly between the second and third quarters of the year.

Net Income of Non-Farm Unincorporated Business

Net income of non-farm unincorporated business consists of the earnings of working proprietors from their own business.

(a) Net Professional Income

This group includes independent professional practitioners such as doctors, dentists, accountants, lawyers and engineers. In general, there is little quarterly data available on professional incomes. Quarterly net incomes are therefore apportioned on the basis of a straight line trend between annual benchmarks; current quarterly figures are derived on the basis of a forecast of the annual.

(b) Other Unincorporated Non-Farm Income

The non-farm group of other unincorporated business covers a heterogeneous range of industries. Again, little systematic information on quarterly net income is available for this group. Various methods of estimation are employed to construct the net income series for these industries, including the synthetic operating account, the ratio of net to gross income, and allocation or projection on the base of indexes. In the latter case, the relationship of the index in the net income series for which it is employed as an indicator is sometimes quite tenuous, resting on assumptions of an uncertain nature.

In forestry, quarterly estimates of net income are derived by distributing annual figures on the basis of the change in the number of working proprietors; current quarterly figures are obtained by projections of these estimates.

In fishing, estimates are obtained by the synthetic operating account method. Gross revenue is taken as the value of fish caught and landed as compiled monthly by the Fisheries Section of DBS. From this figure are deducted the various expense items. Quarterly estimates of depreciation are derived by straight line interpolation between annual benchmarks. For the current period, this involves forecasting the annual figure. Other expenses such

as wages and salaries, fuel and repair costs are moved according to the pattern of the value of fish caught and landed.

In hunting and trapping, the annual estimate is distributed evenly over the fall and winter months. For the current period this involves a forecast of the annual.

In manufacturing, the annual estimates are distributed or projected on an index which reflects changes in wholesale prices of selected manufacturing commodities and changes in the number of working proprietors. In construction, net income of working proprietors is allocated and projected on the change in the volume of new residential construction.

Net income of unincorporated retail stores is estimated by applying profit-sales ratios to quarterly sales of unincorporated retail stores. Since 1950, the ratios are based on the quarterly corporation profits survey. For prior years, the annual net income figures are allocated according to the quarterly pattern established for 1950-1952. Quarterly net income in wholesale trade is obtained by distributing the annual estimate evenly over the four quarters; currently this involves a forecast of the annual.

In finance, insurance and real estate, annual net income of stock and bond dealers is moved according to the value of shares traded on the Toronto stock exchange. Net income in insurance is derived by straight-line interpolation between annual estimates. Net income in other financial groups is distributed according to the movement of net income in the above two groups.

The various service industries constitute an important segment of the unincorporated business field, but information respecting quarterly movements of net income for this group is fragmentary. The methods of estimation are therefore based on assumptions of uncertain validity.

In laundry and dry-cleaning, barbering, etc., the estimates are linked to the movement of consumer expenditures on similar services.

Net income in undertaking is based on a composite index combining the number of deaths with the consumer price index.

Net income in hotels and tourist camps is based on an index of employment in hotels. In restaurant service, an index of total restaurant sales is used. Net income from boarding and lodging is derived by straight-line interpolation between annual estimates. Miscellaneous business and personal service is adjusted according to the movement of total business and personal service above.

Indirect Taxes Less Subsidies

Indirect taxes represent a part of the market price of goods and services which is not received by factors of production. They are, therefore, not included in National Income, but must be added to factor costs to arrive at total costs entering into market prices.

Subsidies represent amounts contributed by government toward current cost of production. For this reason they must be deducted from factor costs to arrive at Gross National Product at market prices.

(a) Indirect Taxes

Federal indirect taxes consist of: (1) customs import duties; (2) excise duties and taxes; (3) the business share of privileges, licences and permits where no direct service by the government is involved; (4) the levy against farmers under the Prairie Farm Assistance Act. With the exception of the latter item, all these data are available monthly on a collections basis from statements prepared in the office of the Comptroller of the Treasury. The quarterly figure is the sum of the three relevant monthly figures. The Prairie Farm Assistance Act levy is obtained quarterly from the Board of Grain Commissioners.

Provincial indirect taxes on a quarterly basis are obtained since 1951 from almost all the provinces. For the non-reporting provinces, an annual forecast is made and distributed on related indicators as described below or on the quarterly pattern of indirect taxes in a contiguous province,

For the years 1947 to 1950, the provincial quarterly estimates, for the most part, are derived by allocating the annual figure according to the movement of related indicators. Gasoline taxes are distributed in accordance with quarterly sales of taxable gasoline in the years 1947-50, as reported to the Public Finance and Transportation Division (DBS). Retail sales taxes are distributed according to the quarterly value of taxable retail sales (after adjustment for tax exempt sales) in the province in which the tax is levied (data from Retail Trade -DRS). Tobacco taxes are divided according to quarterly releases of tobacco, as reported to the Industry and Merchandising Division, DBS, Real and personal property taxes are allocated equally to the four quarters of the year since they are considered to accrue on a day-to-day basis. All other taxes, including the business share of motor vehicle licences and permits, the amusement tax, taxes on corporations other than on profits, and miscellaneous taxes, licences, permits and public domain revenues. are allocated according to the 1951 pattern of tax collections.

Municipal indirect taxes consist mainly of real property taxes on owner-occupied and rented property. Again, these taxes are allocated evenly throughout the year. Municipal retail sales taxes are allocated according to the quarterly value of taxable retail sales in the provinces where they are levied. All other municipal taxes are allocated since 1951 according to the pattern of the corresponding provincial taxes. For current quarterly periods, these procedures involve a forecast of the annual.

(b) Subsidies

Direct subsidy payments by the federal government are obtained on monthly basis from expenditure statements prepared in the office of the Comptroller of the Treasury; the quarterly figure is derived as the sum of the three relevant months.

Trading losses on operations of government commodity agencies, also classified as subsidies in the National Accounts, are available only on an annual basis, and the quarterly estimates are derived by allocating the annual figures equally to the four quarters of the year. For the current quarterly period this procedure involves a forecast of the annual.

Provincial subsidies are obtained from the reporting provinces since 1951. Prior to 1951, provincial subsidies were allocated on the basis of the pattern prevailing in 1951.

There are no subsidies paid at the municipal level.

Capital Consumption Allowances and Miscellaneous Valuation Adjustments

To arrive at Gross National Product at market prices, allowances for current consumption of capital and similar non-cash charges deducted to arrive at the profit, net rent, and net income components of the national income must be added back. Current accounting allowances are used as a basis for the estimates, although these may vary widely from true economic capital consumption. It is convenient, however, to regard "capital consumption allowances and miscellaneous valuation adjustments" as the sum of true capital consumption and various "valuation adjustments", even though the former are not at present completely separable.

Valuation adjustments arise from differences in the concepts of income as reflected in business accounting records and the corresponding concepts relevant for the National Accounts. In some cases, outlays essentially capital in nature are charged by business to current expenses. Capital outlays of this nature are included in the estimates of business gross fixed capital formation in Gross National Expenditure; they must therefore be included as a component of Gross National Product to preserve the balance of the accounts. Conversely, certain non-tangible outlays capitalized by business are deducted under this general heading.

The claim portion of insurance against fire and other damage to business property (including all residential property), is regarded as analogous to depreciation in that it is included in market prices but does not represent income of any factor of production. It is a cost in the maintenance of the national capital and is therefore included under this heading. An estimate is also included for the claim portion of business insurance against financial loss, e.g. fidelity insurance.

Bad debt allowances (less recoveries) are included here since they are deducted in computing net income and profits but do not represent income of any factor of production.

Other items included under this general heading are business scrap and salvage allowances and net business sales of used motor vehicles.

In general, methods by which quarterly estimates of depreciation are derived may be grouped into four main classes. The most important of these relies on the Corporation Profits publication, issued by the Business Finance Division of DBS, and beginning with the year 1950 this is used for distribution or projection of the main components of depreciation for incorporated private companies, government business enterprises (based on the utilities group of private corporations) and unincorporated retail trade. For the years 1947 to 1949, the average pattern of depreciation obtained from Corporation Profits was used to distribute the annual data quarterly.

The second group of estimates are obtained by using synthetic operating accounts. The estimates of depreciation in agriculture and in fisheries are derived in this manner from the preparation of net income of unincorporated business. Depreciation estimated in the calculation of residential rents is used for the housing depreciation.

A third class of estimates is based on the allocation or projection of the depreciation figures according to the movement of related indicators. Thus capital outlays charged to current expenses, and scrap and salvage allowances, are distributed on the movement of quarterly capital formation in new machinery and equipment, Net bad debt write-offs and the claim portion of business and residential insurance are moved on the trend of corporate depreciation. Mining development expenditure write-offs are moved according to depreciation in mining. Trade-in allowances on the sale of used cars are based on the sale of new and used cars.

The fourth estimate is one for which no quarterly information is available. The method employed here is one of interpolation through annual averages and the current figure is obtained by extension. This includes estimates of depreciation in unincorporated business (other than industries explicity mentioned), real estate commissions on the transfer of non-residential buildings, amortization of landlord facilities, commissions on the purchase and sale of stocks and bonds, and other adjustments.

GROSS NATIONAL EXPENDITURE AT MARKET PRICES

Personal Expenditure on Consumer Goods and Services

This component comprises personal expenditure of Canadian residents, including implied expenditure out of income in kind, on consumer goods and services. All types of consumer durable goods are included, with the exception of house purchases, which are regarded as capital goods, and are shown with the estimate of business gross fixed capital formation. The rental value of owner-occupied houses is included, as are the operating costs of private non-commercial institutions and life insurance companies (see page 123, National Accounts, Income and Expenditure, 1926-1956). The estimate includes expenditures of Canadian residents temporarily abroad, (e.g. tourists, members of the armed forces), but excludes expenditures of foreign residents temporarily in Canada, All expenditures that are regarded as business costs are excluded.

The estimates are calculated under three broad categories: commodities, services, and net expenditures abroad.

(a) Personal Expenditure on Commodities

This estimate consists of purchases of commodities by persons, and implied expenditure out of income in kind. The general method of estimating quarterly purchases of commodities is to adjust the quarterly figure of total retail sales to exclude the value of non-personal purchases of commodities at retail, and to eliminate sales of second hand merchandise not assignable to the production of the current quarter. Receipts from repairs and services are also subtracted from the total, since they are included with personal expenditure on services. Commodities purchased by individuals through nonretail outlets are added, as well as certain provincial and local taxes which are not included in the total retail sales figure. The method of estimating each of the above component series on a quarterly basis is described in the following sections. In general, the procedure followed is to allocate annual figures on the basis of monthly retail sales or other data obtained from the various Divisions of DBS; these data are also used to carry forward the quarterly series into current years for which annual information has not yet become available.

(i) Total retail sales

Quarterly estimates of total retail sales are based on the monthly retail sales figures from the Industry and Merchandising Division.

(ii) Non-personal purchases at retail

Non-personal purchases at retail, which are deducted from the estimate of total retail sales, are estimated quarterly by groups. The retail sales

figures relevant to the group are used as the interpolating or extrapolating series for estimates of wholesale sales of automotive dealers, building material, hardware, plumbing and heating equipment; business purchases of new and used motor vehicles, gasoline, oil and grease, automobile parts and accessories, alcoholic beverages, work clothing; wholesale sales by retail establishments; tractors and farm implements and parts; and hay, straw and feed. The value of meals and beverages charged to business and government expense accounts is projected according to the movement of labour income in manufacturing, wholesale and retail trade and government.

(iii) Sales of second-hand merchandise

Since Gross National Expenditure measures only sales of currently produced goods and services, it is necessary, in computing personal expenditure on consumer goods and services, to exclude the transfer value of sales of second-hand merchandise from total retail sales; only the mark-up value of such merchandise is properly included in the figures.

Sales of used automobiles by motor vehicle dealers and used car dealers are estimated on the basis of monthly data from the Industry and Merchandising Division. From this figure it is necessary to subtract the value of trade-in allowances on new and used automobiles and/or the cost of dealer purchases. Estimates of trade-in allowances by motor vehicle dealers are based on monthly data from the Industry and Merchandising Division and a constant mark-up is assumed in the case of sales by used car dealers.

The estimates of trade-in allowances on other used merchandise are projected on the trend of furniture store sales.

(iv) Receipts from repairs and services

Since the estimates in this section refer wholly to commodities, repair and service receipts are deducted from the total of retail sales and included in personal expenditure on services below. The repair and service receipts by garages are projected on the trend of garage and filling station sales. All other repair and service receipts are projected on the trend of total retail sales less restaurants.

(v) Commodities purchased through non-retail

A significant volume of retail sales to individuals occurs through outlets not ordinarily classified as retail stores, and these must be added to the retail sales figures. Included here are retail sales by manufacturing bakeries and dairies (house to house deliveries). The former is projected on a combined index of employment, average hours worked and the price of bread and other bakery products;

and the latter on a combined index of fluid milk sales and milk prices. Sale of beer through factory outlets is projected on the trend of retail beer sales.

Direct consumer sales by farmers are also added insofar as estimates can be made. Direct sales of fuel wood to consumers by farmers is moved according to farm cash income from the sale of forest products. Sale of farm produce by means of house-to-house delivery and markets is projected by a combined index of consumer prices and urban population.

Consumer purchases of fuel oil and kerosene from bulk tank stations are projected on the basis of manufacturers' sales (from the Industry and Merchandising Division) and the price of fuel oil. Expenditure on electric power is estimated in accordance with a composite index of net generation by utilities and the price of electric power; and expenditure for household gas in accordance with domestic sales to households.

Consumer purchases in railway dining and buffet cars are projected according to the movement of total passenger operating revenues of all Canadian railways obtained from the Public Finance and Transportation Division. Purchases of alcoholic beverages are related to monthly sales of alcoholic beverages (collected by the Industry and Merchandising Division). Purchases of meals and merchandise through hotels and cafeterias and canteens on business premises are distributed in accordance with the movement of retail sales of restaurants, obtained from the Industry and Merchandising Division. Retail sales by manufacturers, wholesalers, service establishments and miscellaneous outlets are projected on the basis of related retail sales data furnished by the Industry and Merchandising Division.

The service portion of meals and alcoholic beverages served for on-premise consumption must be deducted from retail sales and added to services since the estimates in this section refer wholly to commodities. The service portion on meals is assumed to be 25% of the retail price, while for alcoholic beverages available data are extrapolated on the basis of sales of spirits, beer and wines to licensees obtained from the Industry and Merchandising Division.

(vi) Provincial and local taxes

In general, retail sales estimates include federal sales and excise taxes, but do not include certain types of local and provincial sales taxes. These must, therefore, be added to bring the estimates of retail sales to persons to a market price valuation. Data are obtained in connection with the quarterly estimates of indirect taxes.

(vii) Income in kind, goods

An imputation is made to personal expenditure for the value of goods consumed out of income in kind. In each case the figures included in expendi-

ture are based on the quarterly estimates used for the income side. The estimate of food and fuel consumed on farms is a part of the calculation of net farm income prepared by the Agriculture Division. Food received and consumed by non-agricultural workers is computed in connection with the estimates of wages, salaries and supplementary labour income. The value of lodging supplied to both farm and non-farm workers is not included here, being classified to the services estimate. Estimates of food and clothing issued to the armed forces are prepared in connection with the figures of military pay and allowances.

(b) Personal Expenditure on Services

This includes the value of services rendered directly to individuals as distinct from those rendered to business or to government. The general method of estimating the quarterly figure is to allocate the annual benchmark on the basis of an interpolating series, and to carry the resulting quarterly estimate forward to the current period by projection.

(i) Estimates based on actual or directly related information

For certain classes of services fairly reliable data are available to serve as the interpolating or extrapolating series. Bridge, tunnel and ferry tolls are distributed in accordance with Canadian reentries at border points; expenditure for transportation on steam railways, electric railways and buses, and air carriers, in accordance with monthly passenger operating revenues; expenditure for postal service in accordance with monthly post office revenues; expenditure on express service in accordance with express operating revenues of railways.

(ii) Estimates explicitly articulated with the income side

Other service groups included in the estimates of personal expenditure on services are explicitly articulated with the income side of the accounts, the estimates being computed in connection with the calculations of components of the Gross National Product. Farm and non-farm residential space rents, paid and imputed, are calculated in connection with the rent component of investment income. Wages and salaries (including income in kind in the form of food received) of domestic servants are calculated in connection with the estimate of wages, salaries and supplementary labour income,

Personal expenditure for board and lodging is taken as being equal to net income from boarding and lodging, which is included in net income of unincorporated business. The figure is included on a net basis in this case since expenses relating to boarding and lodging are already included in personal expenditure for food, rent, fuel and so forth.

Estimates of personal expenditure for services of physicians and surgeons, dentists, nurses, lawyers, and miscellaneous health services, are all related to the estimates of net income of the professional service groups.

The value of free lodging supplied to non-agricultural workers occupying non-residential property such as bunk-houses, hotels and steamships, is added as an imputed expenditure. The calculation is made in connection with wages, salaries and supplementary labour income.

Estimates of banking services imputed to individuals and estimates of the net personal expenditure on consumer debt service are based upon calculations made in investment income.

(iii) Estimates based on indirect evidence

A substantial part of the services estimate is allocated according to the movement of series which are not directly related to the data to be distributed. For the most part, the methods used for this group of estimates have had to be based on certain assumptions concerning relationships. The fact that these assumptions are quite often tenuous must be taken into account in assessing the quality of this group of estimates.

In general, the methods of interpolating or projecting are based on indexes of price and population, retail sales of related commodities and straight line projection of trend.

Among the major components to be found in this group are: personal expenditures on repairs and maintenance, hospital services, telephone charges, taxi service, cables and telegram charges, prepaid medical care and expenses of insurance companies.

(c) Net Personal Expenditure Abroad

This net adjustment is necessary to include, in personal expenditure, the expenditure of Canadian residents in foreign countries, and to exclude the expenditures of non-residents in Canada. The adjustment covers net expenditures of members of the armed forces, as well as net tourist expenditures. In addition, net private remittances to non-residents are included to correspond to the contra-entry in the balance of payments component. To the extent that gifts in kind sent abroad do not appear in retail sales (e.g. Red Cross parcels) an estimate of their value is also added. (Data are obtained from the Balance of Payments Section of DBS). An arbitrary adjustment is made to Canadian tourist expenditures abroad to exclude expenditures chargeable to business expense accounts.

Government Expenditure on Goods and Services

This component consists of the outlays for goods and services of the federal, provincial and municipal governments (including municipal school corporations). The figure is essentially a residual derived by eliminating from government budgetary expenditures all outlays which are not made directly to purchase new goods and services, such as subsidies, transfer payments to individuals and private non-commercial institutions, transfers to

other governments, losses of government-owned enterprises, provisions for debt retirement, reserves, write-downs and other bookkeeping adjustments, and purchases of land and used capital assets. The expenditure of the Post Office Department is also eliminated, since this agency is treated in the National Accounts as a government business enterprise. Finally, government expenditures on goods and services which take place outside the framework of the budgetary accounts are added.

The figure of government expenditure on goods and services includes an estimate of gross imputed rent on government-owned buildings. The imputed rent is based on a projection of a 1954 annual benchmark for space owned by government and an especially constructed commercial rent index; it is assumed to accrue equally throughout the year.

Since 1952, a timing adjustment to current government expenditure data is made to convert government capital expenditures from a cash to an accrual basis. The adjustment represents the difference between the estimate of cash outlays on capital items derived from government returns and the estimate of the value of work put in place, based on employment and related data, as described under the section on Business Gross Fixed Capital Formation.

At the federal level, all of the budgetary data necessary to carry out the above procedures are available from monthly expenditure statements of the Comptroller of the Treasury. It should be noted that expenditures on goods and services charged in the supplementary period of the fiscal year by the Comptroller of the Treasury are divided equally between the first and second quarters in the National Accounts presentation, Although the bulk of the supplementary payments on goods and services probably relate to first quarter transactions, the mechanics by which a number of related series are recorded in the National Accounts (e.g. imports, change in inventories) requires that, for consistency, an adjustment be made to include a part of supplementary period outlays in the government expenditure component in the second quarter. The reason for this is that the Treasury books are held open until April 30th, to permit payment with respect to transactions completed prior to March 31st. The exact amount of the required adjustment is not known, but it is estimated to be approximately one-half of the total supplementary period payment. Other outlays made in the supplementary period such as transfers to persons, subsidies, etc., are included in the second quarter.

Adjustments are made to goods and services to eliminate amounts charged to the defence appropriation which are not related to current production. For example, prior to 1959, shipments from stocks

Pexpenditures on goods and services financed by inter-governmental transfers are included at the level of the government which spends the funds for goods and services.

of previously produced military equipment to NATO countries are reflected in the government accounts as budgetary expenditure, and it is necessary to delete these amounts and to add back the outlay for new goods and services made from the Defence Equipment Replacement Accounts. An adjustment is also made to allocate government housing expenditure for the armed services to the quarter in which the actual construction was carried out.

Federal extra-budgetary expenditures on goods and services are added to these figures. Included here are net purchases by various government commodity agencies such as the Agricultural Prices Support Board, and from the Defence Production Revolving Fund. Information is obtained quarterly from the Departments of Agriculture and Defence Production. Expenditures of agencies such as the Canadian Broadcasting Corporation, which are not treated as government business enterprises, are also added. These figures are derived quarterly by allocating the annual data evenly throughout the year; for current periods, this involves a forecast of the annual figure.

Since 1951, at the **provincial** level, a similar process yields quarterly government expenditure on goods and services from returns of the provinces. For the years 1947 to 1951 the quarterly pattern prevailing in 1951 was employed to distribute the annual data.

No data were available on the quarterly movements of municipal government expenditures. These have therefore been distributed according to the provincial patterns, it being assumed that the movement in the municipal data follows closely the pattern of provincial expenditure on goods and services.

Business Gross Fixed Capital Formation

Business gross fixed capital formation, as defined in the National Accounts, includes expenditures for new construction and new machinery and equipment. Expenditures of persons for new housing (including major alterations and improvements and supplementary costs) are also included, since individuals, in their capacity as home-owners, are treated as business enterprises. Thus, this component covers gross capital formation of the private sector of the economy and government business enterprises. Expenditure on new construction and equipment for general government purposes is excluded since it is included in the component government expenditure on goods and services.

In general, the quarterly figures of total private and public gross fixed capital formation are obtained by allocating annual data on the basis of specially constructed indicators and the government portion is then excluded. For current quarters for which no annual data are available, the series are carried forward according to the movement of these indicators. The interpolating (or extrapolating)

series are prepared for each of the main components of the annual figures: new residential construction, new non-residential highway and railway construction, new non-residential building and other engineering construction, and new machinery and equipment.

In the case of new residential construction annual value estimates of new residential construction are prepared by the Economic Research Department of Central Mortgage and Housing Corporation, using a formula which takes into account physical units (starts and completions), appraised unit cost of construction, and combined cost indexes of wage rates of construction workers and residential building material prices. Annual estimates are allocated into quarterly estimates on the basis of starts and completions, units under construction and a combined cost index; and projections to current quarters are similarly based. Annual and quarterly data on housing outlays made by federal government departments (the value of which is included with government expenditure on goods and services) are also provided by the Corporation. The new residential construction component of business gross fixed capital formation is derived by taking the difference between the total and the government series, as estimated above.

Quarterly estimates of new road and highway construction, including water and gas mains and sewage systems, are obtained by interpolation of the annual data on the basis of a composite index which incorporates data on employment and average hours worked in highway construction (volume component) and prices of construction materials and average hourly earnings (price component). A major part of this item is included in government expenditure on goods and services and is therefore excluded from business fixed capital formation. Estimates of outlays for new railway construction are distributed on the basis of employment, average weekly earnings and construction material prices, For current years, prior to preparation of annual estimates, the index is used to project the latest available annual estimate.

Quarterly estimates of new non-residential building and other engineering construction are obtained by interpolation (or projection) on the basis of composite indexes which take account of employment, average hours worked, building material prices, and average hourly earnings of construction workers. An adjustment is made to the value series to eliminate government construction, which is included with government expenditure on goods and services.

Quarterly estimates of **new machinery and equipment** are derived by allocating the annual estimates on the basis of data reflecting domestic supply, i.e. total Canadian shipments of various types of machinery and equipment, adjusted to include imports and to exclude exports. The composite series, which is also used to project current quarterly estimates, covers such components as agri-

cultural implements, non-agricultural machinery and equipment, trucks, passenger vehicles, and other transportation equipment. Expenditures by government for machinery and equipment are deducted, to yield private investment in machinery and equipment.

Change in Inventories

The net change during the quarter of holdings of inventories must be recorded in the Gross National Expenditure in order to allow for that portion of current production which remains unsold at the end of the quarter (positive change in inventories), or to eliminate that portion of previous quarters' production which is included in sales of the current quarter (negative change in inventories).

The inventory estimates are presented in two parts; 1) non-farm business inventories which include changes occurring in private business and government business enterprises, and 2) farm inventories and grain in commercial channels which include changes occurring in livestock on farms and grain inventories held on farms and in commercial channels. In the former, net purchases by various government commodity agencies not organized as business enterprises are excluded as they are included with government expenditure on goods and services. Government pre-financing of private inventories is included with government expenditure on goods and services and is therefore excluded.

The method of recording all estimated quarterto-quarter changes in inventories is based on the physical change during the period, valued at average prices of that period, rather than on the change in their book valuation. In recording inventories in this manner, inventory "gains" and "losses" which arise through differences in the replacement cost of stocks consumed and their book valuation at the time of consumption are eliminated. However, in using a value of physical change concept for non-farm business inventories, an adjustment has to be made to corporate profits and net income of unincorporated businesses, both of which reflect the method used in arriving at book valuation of inventories; this adjustment is shown in the accounts as the inventory valuation adjustment. For farm inventories and grain in commercial channels, this adjustment is largely unnecessary due to the direct calculation of inventories in value of physical change terms. A comprehensive description of methods used to compute value of physical change and inventory valuation adjustment series from conventional business book valuations, may be found in National Accounts, Income and Expenditure, 1926-1956, paragraphs 473-515.

Following are the sources and methods used to estimate non-farm business inventories by industrial groups:—

In forestry, quarterly book values are derived by projecting an annual base figure on the trend of the value of stocks of pulpwood cut and in streams but excluding that held at mills. The information on physical stocks is collected in monthly surveys carried out by the Industry and Merchandising Division of DBS. The prices with which to value these physical stocks were obtained annually from the same source, and have been advanced on the basis of two related indicators, average weekly earnings in the logging industry and average unit value of pulpwood exported.

In computing the quarterly book values of mining inventories, calculations are made separately for finished goods and raw materials. For finished goods, quarter-end holdings of physical inventories of iron ore, asbestos and coal mines are obtained from the Industry and Merchandising Division. Price series to value the physical stocks are obtained from the Prices Division of DBS. The resulting quarter-end book values are used as an indicator of the movement of total finished goods in the mining industry. Quarterly inventory holdings of raw materials are assumed to move in accordance with an index of payrolls in the mining industry. The sum of the two series so computed constitutes the book values of total inventories held in the mining industry.

Book values of inventories held by manufacturing industries are based on a monthly sample survey conducted by the Industry and Merchandising Division. The survey covers raw materials and supplies, goods-in-process and finished goods for all seventeen manufacturing industrial groups. The information obtained monthly from the sample survey is adjusted to the annual benchmark data which are derived from the annual Census of Production, Adjustments based on information contained in the sample are also made to exclude trading inventories held at selling outlets which are considered part of wholesalers' inventories, inventories financed by government progress payments, as they are included in government expenditure on goods; and to include the value of goods owned by manufacturers but purchased for re-sale only.

Quarterly estimates of inventories of building materials held by construction contractors are based on the movements of construction employment and a 3-month average of building material prices. Information is obtained from the Employment Section and from the Prices Division of DBS. The resulting series is used to interpolate between annual estimates and for projection.

In transportation, storage and communication, quarterly inventory holdings are derived by moving between annual book value estimates and projecting current estimates on the basis of information supplied by Canadian Pacific Railways and Canadian National Railways as well as supplementary information obtained about inventories of materials and equipment held by telephone companies.

The method of estimating quarterly inventories held by public utilities is to interpolate between annual benchmarks using a 3-month moving average of employment in public utilities; for current quarters, the estimates are carried forward using a similar method. The data on employment are obtained from the Employment Section.

Quarterly data on the trend of holdings of wholesale inventories by twenty trade groups are obtained from the Industry and Merchandising Division of DBS and are based on a monthly sample survey. Physical volume data on petroleum are obtained from the same source and on coal from the Dominion Coal board. Both are valued at prices obtained from the Prices Division of DBS. This information is used to interpolate between annual book value estimates and to project current estimates. Manufacturers' sales outlets stocks, which are classified under wholesale, and agents' and brokers' stocks are advanced between annual book value estimates and projected on the trend of manufacturers' inventories.

Most of the quarterly information concerning stock holdings of retail trade is based on monthly sample surveys, stratified by store type, carried out by the Industry and Merchandising Division. In the case of chain and department stores, the monthly survey coverage is very close to being complete and actual inventory holdings are reported. The trends of independent store inventories which are based on a much smaller sample, are calculated mainly from monthly sales and purchases data applied to beginning-of-the-year inventories (collected annually). The trend of inventory movements derived in these surveys is used to interpolate between annual book value estimates and to project current estimates. Additional information on coal stocks is obtained from the Dominion Coal Board. New car inventories based on shipments from factories adjusted for imports, exports and retail sales are also used in deriving retail trade inventories.

No quarterly information is available on inventory holdings of the finance, insurance, real estate and service groups. They are assumed to move in accordance with the quarterly trend of the manufacturing, wholesale and retail trade inventories.

The change in farm inventories is calculated as indicated in the section, "Accrued Net Income of Farm Operators from Farm Production".

The value of physical change in **grain in com**mercial channels is obtained quarterly by applying to the quantity changes supplied by the Agriculture Division of DBS, the average initial price paid to producers during the quarter by the Canadian Wheat Board, in the case of wheat, and the average market prices in the case of coarse grains.

As has been indicated in the two preceding paragraphs, farm inventories and grain in commercial channels are calculated directly in value of physical change terms. However, two minor adjustments to the income side are necessary, to allow for the fact that earnings arising out of the operations of the Canadian Wheat Board are based on inventories valued in the conventional business manner and similarly to allow for private grain dealers. In the former case the adjustment is made directly to accrued net income of farm operators from farm production, and in the latter, it is included in the published inventory valuation adjustment.

Inventory Valuation Adjustment

As indicated above, for national accounting purposes, the change in the value of inventories should be measured in current prices of the period under consideration. Because this method of valuation differs from that employed in conventional business accounting practices, an adjustment to corporate profits and net income of unincorporated businesses is necessary; for both these income aggregates reflect inventory valuation according to business practices. The adjustment is shown explicitly on the income side of the accounts.

A detailed description of the problems faced and the methods used to derive the adjustment, may be found in *National Accounts*, *Income and Expenditure*, 1926-1956, paragraphs 493-515 inclusive.

A brief outline of the steps taken to arrive at a value of physical change and the inventory valuation adjustment is outlined below:

- i) Estimate book value of inventory from reported data;
- ii) Establish the deflator price index relevant to the period of acquisition of stocks, (taking into account turnover period and predominant business accounting practices);
- iii) Calculate the constant dollar book value
 ((i) + (ii));
- iv) Calculate the quarter-to-quarter change in constant dollar book value (from (iii));
- v) Establish the revaluer price index (based on average prices during the current period);
- vi) Calculate the value of physical change in current dollars ((iv) x (v));
- vii) Enter the quarter-to-quarter change in reported book values from (i);
- viii) Calculate the inventory valuation adjustment ((vi) - (vii)).

These steps are done in considerable detail for manufacturing, where inventories are identified within industries as raw materials, goods in process and finished goods, and for wholesale and retail. In all, about one hundred items or industry groups are dealt with separately. Price data are supplied by the Prices Division of DBS.

Exports Minus Imports

Because a part of Canada's current production of goods and services is sold to non-residents, it is necessary to add the value of exports to arrive at a final accounting of current production through sales. Conversely, because sales to persons, governments, business on capital account and non-residents, include goods and services produced by non-residents, i.e. imports, it is necessary to subtract these in order to arrive at a correct valuation of Canadian output,

It should be noted that the terms exports and imports are used here in a broad sense to include both goods and services; interest and dividends received from non-residents are regarded as receipts for the service of capital and are included with the export series, while interest and dividends paid to non-residents are regarded as payments for the service of capital and are included with the import series. It will be recalled that adjustments corresponding to these dividend and interest transactions are made to investment income on the income side of the National Accounts. In addition, gold production available for export, tourist and travel expenditures of non-residents in Canada, freight and shipping credits earned on Canadian account and various receipts for business services are included in the export figures; tourist and travel expenditures of Canadians abroad, and freight and shipping charges and business service costs incurred by Canada on foreign account are included with the import series.

The quarterly figures appearing in the National Accounts are the gross receipts and payments on current account prepared by the Balance of Payments Section of DBS. These figures are published regularly in the reports Quarterly Estimates of the Canadian Balance of International Payments. For current quarters, only one adjustment is necessary

to bring these figures into line with National Accounts definitions; emigrants' funds and inheritances are deducted from gross current debits (imports), and immigrants' funds and inheritances are deducted from gross current credits (exports). These unilateral items do not represent payments for goods and services, nor are they related to the current earnings of Canadian or foreign factors of production; they are treated as transfers of capital which are not included in the National Income, (although they occur with sufficient regularity to be considered as "current" transactions for Balance of Payments purposes).

For a detailed description of the sources and methods used by the Balance of Payments Section of DBS, reference should be made to *The Canadian Balance of International Payments*, 1926 to 1948, Dominion Bureau of Statistics, 1949, and also to *The Canadian Balance of International Payments in the Post-War Years*, 1946-1952, Dominion Bureau of Statistics, 1953.

Residual Error of Estimate

As has been indicated, substantially independent estimates are made for the Gross National Product and the Gross National Expenditure. Since both of these aggregates measure the value of goods and services produced by Canadians in a given quarter, they should add up to the same sum. In fact, however, there is a statistical discrepancy between the two totals due to the shortcomings in available statistics. On the assumption that the "best" estimate of the common total is half way between the two independently computed totals, the statistical discrepancy is divided into two equal parts and onehalf is allocated to each of the two sides of the account under the heading of "residual error of estimate". In this manner, balance is achieved between the two sides of the account.

SECTION 2

MISCELLANEOUS NOTES

SEASONALLY ADJUSTED NATIONAL ACCOUNTS DATA

Seasonal variation may be viewed as a "repetitive intra-annual fluctuation". The majority of the time series given in Tables 1-9 of this report exhibit clearly defined seasonal patterns, which recur with characteristic regularity. Such fluctuations reflect the influence of a variety of factors. Climatic conditions, for example, influence the production and marketing of crops, the intensity of cutting operations in the woods, the purchase of winter and summer clothing, the shipment of commodities through the St. Lawrence River, and so on. The observance of Christmas and Easter is reflected in the buying habits of consumers, with levels of purchasing fluctuating sharply in these periods. Trade practices also exert their influence-for example, the dates of the annual appearance of new automobiles are an important factor in the seasonal movement of automobile purchases. Thus, climate, social institutions, trade practices and a myriad of other factors all generate repetitive intra-annual fluctuations in statistical time series.

In dealing with a time series in which such seasonal fluctuations occur, it is usually difficult to detect the basic underlying movements of the data since these are often obscured or hidden by the regular seasonal upswing or downturn. Thus, in order to isolate turning points or trends in the basic economic situation, it is necessary to eliminate the effects of seasonal movements from economic data. Although this elimination, or seasonal adjustment, can be made in approximate terms only, seasonally adjusted data nevertheless provide an important aid in the analysis of time series and can shed considerable light on underlying trends or tendencies in the economy.

The general approach to the seasonal adjustment of economic time series adopted by the Dominion Bureau of Statistics is the ratio-to-moving-average technique. A detailed outline of problems and methods in seasonal adjustment has been given in DBS. Reference Paper *77-Seasonally Adjusted Economic Indicators, 1947-1955, (published in 1957), and will not be further elaborated in this section. Recent developments in the application of electronic computers to the problem of seasonal adjustment have permitted an adaptation of the ratio-to-moving-average technique to

machine methods.² The following paragraphs deal briefly with the procedures followed in seasonally adjusting series by the use of electronic computors.

The adaptation of electronic computers to the seasonal adjustment of economic time series by no means disposes of the need for careful professional scrutiny of the final seasonally adjusted series. While the machine technique has been thoroughly tested and found to provide a seasonal adjustment at least as good as that of the best hand series in the great majority of cases, there are still problem areas which require the judgment and professional scrutiny of the trained statistician. All of the material which has been processed on an electronic computer has been subjected to the most careful testing to ensure that the quality of the seasonally adjusted data met acceptable standards. Out of a total number of 250 series processed on a computer, it was found that about 90 per cent were successfully handled by the machine, but that a small number of cases still required adjustment by a hand technique.

The advantages of electronic computers in the seasonal adjustment of economic time series are, first, that it can perform mass operations on economic data quickly and economically, where formerly laborious and costly manual operations had to be carried out; and secondly, that it tends to narrow the subjective element in seasonal adjustment by enforcing uniformity and standardization across areas where formerly individual statisticians carried out their own hand seasonal adjustment, with the possibility that differing evaluations might be made. It should be noted that although the machine method was generally used for the period 1947 to 1957, from 1958 to date a large number of the series have been carried forward on the basis of the hand adjustment. The time saved by the use of the electronic computer does not prove to be significant in dealing with revisions of quarterly series which cover only two or three years.

The Method

The general approach employed on the computer is one of reiteration. A preliminary seasonally adjusted series, derived in much the standard manner, is smoothed by a weighted moving average, giving a

¹ Burns and Mitchell, Measuring Business Cycles, National Bureau of Economic Research, New York, 1946, p. 44.

The program of seasonal adjustment by electronic computer techniques was developed by the U.S. Bureau of the Census, in Washington, D.C. See also Seasonal Adjustment by Electronic Computer Methods, by Julius Shiskin and Harry Fisenpress, Technical Paper #12, National Bureau of Economic Research, New York, 1957.

more sensitive indicator of the underlying trend and cycle, with the erratic elements removed. This result is then used as the basis of a second round of calculations. The ratios of the original data to the smoothed preliminary seasonally adjusted series are calculated. These ratios are then used to compute a moving seasonal; any highly irregular ratios are removed by a formula which gives much less weight to those ratios which are outside the range of a given tolerance. The final seasonal ratios are then divided back into the original data to yield a final seasonally adjusted series. Essentially, then, the computer method employs the same principles that are used in the hand technique.

It is at this point that quarterly series are subjected to professional scrutiny to ascertain whether the machine has adequately seasonally adjusted the series. To facilitate this analysis, charts of the old hand seasonal adjustment and the new computer seasonal adjustment were made to pinpoint major divergences. Tier charts, based on the new seasonally adjusted series, were also developed to ensure that no residual seasonal remained in the series. It was found that in the great majority of cases, the computer method could be accepted. However, in cases where the irregular factor was high for a series, some adjustments to the results proved necessary. Residual seasonal appeared quite frequently in these series. It was found that the seasonal factors computed by the machine, in cases of series with a high irregular, tended to be too inflexible, not fitting a succession of three or four deviations closely enough, with the result that a peak or a trough would repeat itself for a specific quarter in the seasonally adjusted results for three or four years. Such series were modified by hand to allow greater flexibility of the seasonal ratios.

Due to the fact that the change in inventory series are made up of plus and minus items, these series did not lend themselves to adjustment by the electronic computer. They were therefore adjusted by a hand technique based on an absolute, rather than a multiplicative relationship between the original data and a moving average of the original data.

It should be understood that considerable scrutiny of the unadjusted data is necessary prior to processing for seasonal adjustment. This can be best described as an attempt to minimize the effect of high irregulars on the computation of the seasonal. Strike adjustments are one illustration of this procedure. Here the unadjusted data are prepared for machine processing as if the strike had never occumed. This can be easily accomplished in an employment series by adding back estimated layoffs due to the strike. If this procedure were not followed the first approximation to the trend cycle component of the series would be deflected off its course both prior to and subsequent to the strike. Seasonal-irregular deviations, and ultimately the

seasonal factors themselves would also be affected adversely during this period. Once the machine has calculated the seasonal factors, these are applied to the original unadjusted series, so that the strike appears in the final seasonally adjusted series.

By analogy this type of correction can be carried to other areas, except that it may not be as simple a matter to anticipate how the series would have behaved if the irregular event had not occurred.

Where a sudden and drastic shift in the seasonal has taken place due possibly to a statistical break or a change in government regulations, such series must be treated as two distinct series (before and after the break) for seasonal adjustment purposes. If this were not done, moving seasonal factors would move slowly and smoothly through such a period, adversely affecting the computation of the seasonal for a number of years.

Special Problem of Seasonally Adjusting Crop Production and Accrued Net Income of Farm Operators

In the case of crop production, the ordinary methods of adjusting the series for seasonal movements are inadequate. Crop production is characterized by concentration of output in the third quarter of the year, and by large and erratic fluctuations in amplitude from year to year. Ordinary techniques of seasonal adjustment do not appear to be appropriate for time series of this nature, and give rise to results which are capable of misinterpretation. A simple expedient has therefore been employed to handle the problem of seasonally adjusting crop production. The annual value of crop production is divided into four parts and allocated equally to each of the four quarters of the year in the seasonally adjusted tables. In going into a new year, before the crop is known, production is estimated on the basis of average yields of preceding years, estimated acreage and initial prices. This preliminary first quarter estimate is revised later in the year as actual data become available.

More specifically, the treatment is based on the following procedure:

Step 1 — The change in grain inventories is broken down into two parts—(a) depletions, which are continuous throughout the year; and (b) additions, which are single events occurring in the third quarter of each year, i.e., the harvesting of the crop.

Step 2 — The depletions data are seasonally adjusted by a standard technique. (The current value data can thus be used analytically in conjunction with the farm cash income series, the export series, changes in grain in commercial channels, and so on, all of which are also seasonally adjusted by a standard technique).

Step 3 — The additions to grain inventories, i.e., the crop, is divided by four and allocated equally to each of the four quarters of the year. All of the

data are available in terms of physical quantity units, and can be valued both in terms of base year prices for constant dollar series and current year prices for current dollar series. This treatment of the crop is arbitrary, but it has the advantage of isolating the problem and treating it independently of all other items in the system.

It may be noted that the divided-by-four technique is used in the case of crop production only, since it is only here that the special difficulties noted above arise, Livestock and other items

in the farm sector are estimated on a quarterly basis and deseasonalized by standard techniques.

In order to depict more clearly movements in the value of production in the non-farm sector of the economy, an additional line in italics has been inserted in Tables 1 and 10 which shows "Gross National Product at market prices, excluding accrued net income of farm operators from farm production". Details of the seasonally adjusted farm inventories series (including the item crop production are shown in Table 11.

CONSTANT (1957) DOLLAR ESTIMATES OF GROSS NATIONAL EXPENDITURE

Changes in the value of Gross National Expenditure arise from changes both in quantities and in prices. The constant dollar estimates are designed to remove the effect of price changes from the value data and thus to facilitate an understanding of movements in real production and changes in the direction and rate of growth of real consumption and investment.

Since both the deflation and seasonal adjustment processes attempt to derive basic underlying movements from actually collected statistical data by means of mathematical techniques, quarter-to-quarter changes in the constant dollar series are subject to a margin of error greater than in the current dollar series. This point should be borne in mind in interpreting the data, and little significance should be attached to small changes in either the constant dollar series or in the implicit price indexes.

For any published component of Gross National Expenditure, as well as for the total, the current dollar series divided by the corresponding constant dollar series will yield an implicit price index that is currently weighted. Such price indexes may be derived both for the unadjusted and for the seasonally adjusted data. Quarter-to-quarter changes in these indexes reflect not only pure price change, but also changing expenditure patterns within and between groups. For the unadjusted data, these changes in expenditure patterns are significant because of seasonal variation. The implicit price indexes based on the unadjusted data, therefore, should not be used for price analysis. In the case of the seasonally adjusted data, however, only small changes in expenditure patterns occur and the implicit price indexes usually provide a reasonable measure of price change. The data are more accurate for the period from 1956 to date than they are for the prior period.

Method of Seasonal Adjustment

A seasonally adjusted constant dollar series may be obtained by either of two methods. The first, known as the direct method, involves the seasonal adjustment of the constant dollar data themselves.

The second, known as the indirect method, involves the deflation of seasonally adjusted current dollars with price indexes which have also been adjusted for seasonality. Both approaches have been used in deriving the published estimates.

A problem inherent in the indirect method of seasonally adjusting the constant dollar data is the difficulty of seasonally adjusting price indexes. The irregular component of price indexes is generally large in relation to the size of the usually small seasonal component; the latter is, therefore, at times hard to identify. On the other hand, the direct method of seasonal adjustment requires that differences in judgement do not occur in the estimation of the seasonal component as between the current and constant dollar series.

Both approaches were tested for major components of Gross National Expenditure. The tests showed that the differences in the resulting constant dollar series were usually small, so that in practice either the direct or the indirect approach could be used. Since most of the current dollar series in the period 1947 to 1956 inclusive, had been seasonally adjusted by the electronic computer, the constant dollar series were also adjusted by the computer, in order to ensure consistency of treatment.

For the most part, the current dollar series from 1957 to date had not been adjusted on the electronic computer program, but were carried forward by hand techniques. In order to ensure that no inconsistencies developed in the derivation of seasonal patterns as between the current dollar and the constant dollar series, the indirect method of seasonal adjustment was employed; that is, the seasonally adjusted current dollar series were divided by a set of seasonally adjusted price indexes. Thus, the constant dollar data for both time segments—1947 to 1956, and 1957 to date—were seasonally adjusted by the method best calculated to ensure consistency as between the current and constant dollar estimates.

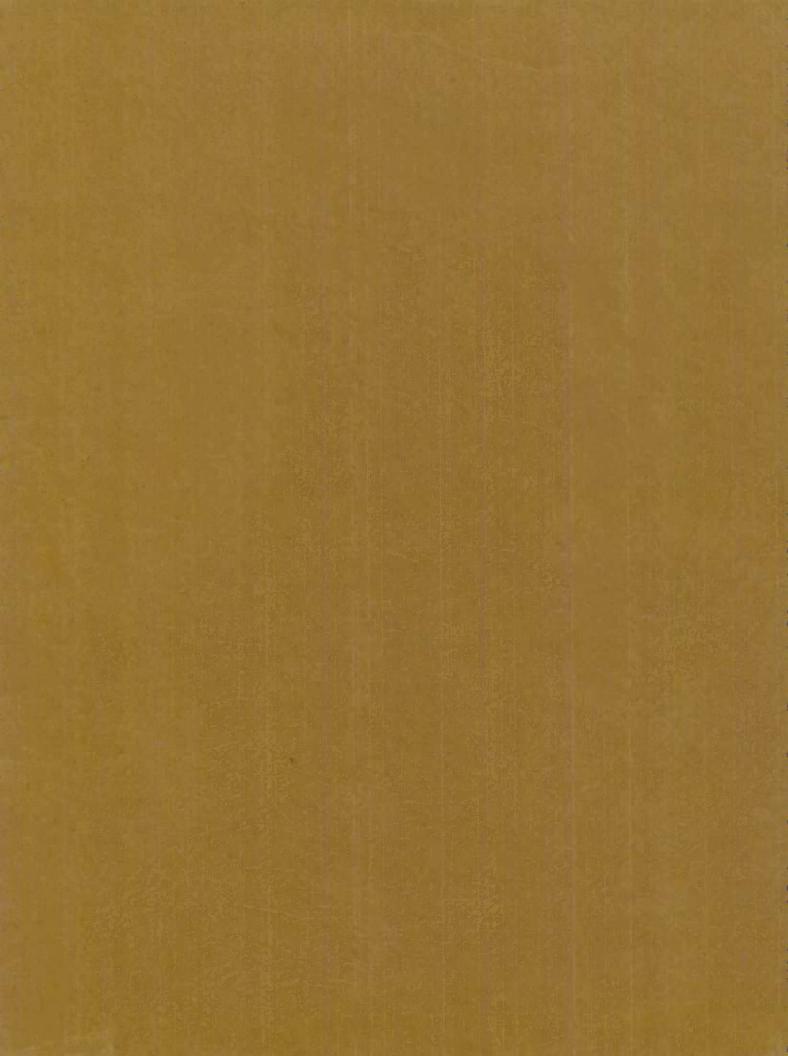

Weight Basis

In the 1949 constant dollar series, Gross National Expenditure and its components are valued in average, annual 1949 prices. Prices of a recent year are more appropriate for valuing production currently, and for this reason, the component series of Gross National Expenditure from 1956 forward were re-valued with the average annual prices prevailing in the year 1957. The Consumer Price Index of DBS was revised to incorporate weights based on the 1957 Family Expenditure Survey. Since approximately two-thirds of Gross National Expenditure is deflated with price indexes from the Consumer Price Index, 1957 was selected as the choice for a new base year.

The period from 1947 to 1955 inclusive, remains on a 1949 weight base, although it is expressed in 1957 dollars. For the years 1947 to 1955 therefore, there will be no change in year-to-

year movements between the 1957 dollar series, and the 1949 dollar series heretofore published. Each of the major components, as well as total Gross National Expenditure has been arithmetically converted from 1949 dollars to 1957 dollars. The conversion factors are based on price relations in the year of overlap, 1956. As a result of this conversion process, the components will no longer sum to the aggregates. Adjusting entries, reflecting the difference between the sum of the components and the aggregates appear in both the unadjusted and the seasonally adjusted data for the period 1947 to 1955. No statistical significance should be attached to these adjusting entries.

For a more detailed discussion of the concepts and methods underlying the construction of constant dollar data, the reader is referred to the National Accounts, Income and Expenditure, 1926-1956, Section "E".
