Farm Business Performance: Estimates from the Whole Farm Database

Introduction

Purpose: The purpose of this paper is to investigate the performance of farm businesses in Canada, to determine the relation of profitability to size as measured by financial indicators. Are bigger farms more profitable? Is the relation of profitability to size sufficient to describe farm businesses?

Hypothesis: that the curve of profitability related to size is an upside-down U-shape. This would indicate that profitability increases as size increases up to a certain point and then begins to decrease as size continues to increase.

Discussion of process

Creation of indicators: The 1992 Taxation sample, some 64,000 records, was used as the basis of this analysis. Thus the financial variables represent the 1992 fiscal year, the latest year for which tax information is available.

The taxation sample was divided into three profit groups by the criteria of low, average, and high performance. Performance was measured as operating earnings per dollar of total agricultural operating revenues. Operating costs were defined as total operating expenditures plus depreciation charges less interest expenses. Operating earnings are the difference between total operating revenues and operating costs. (See Appendix A for a description of the components of the income statement and the associated codes used in the Taxation file).

The size of farm businesses was defined using sales classes as described in Appendix A.

The charges for interest were not included in this analysis because the objective of this paper was to look at the operating performance of the farm business. To include interest charges adds the factor of indebtedness to the picture. A business which is other-wise well-run could have very high or very low debt charges to cover, depending on factors extraneous to the operation of the farm such as the age of the farmer or the year in which the debt was incurred.

Definition: Low performers did no better than break even. Average had operating expenditures and depreciation less interest of 70 to 99 cents per dollar of revenues. High performers spent less than 70 cents per dollar of revenues.

Observations:

Overall, for all records at the Canada level, the curve of operating earnings per dollar of revenues is indeed an upside-down U-shape. The lowest performance is measured for the smallest farms. As the size of farms increases, so does profitability up to sales class 5 (\$100,000-\$250,000) after which it declines.

However, when the sample is broken up into the three groups of low, average, and high farms a very different picture emerges. (See Table 1). The group of low performers loses less money with increasing size. The group of average performers is just that: all sales classes show about the same level of profitability. The third group, of high performers, decreases in profitability with increasing size, levelling off in the three largest sales classes. The smallest farms in this group are the most efficient, in sharp contrast to the group of low performers where the smallest farms are the least efficient.

At the provincial level essentially the same results are found for the three groups. The low performers increase in profitability with increasing sales, the average group exhibits little change, and in the high groups profitability declines and then levels off with increasing sales.

These results were found to be essentially the same when using the results from the 1991 Census of Agriculture. The indicators are not exactly the same conceptually, but are close enough to provide a check on the results from Tax.

| \$500,000 | 0.08 | - 0.10 | 0.11 | 0.40 |
| and over | (5,945) | (960) | (4,540) | (450) |

When operating earnings are broken down into revenues and operating expenditures by profit group and sales class (see Table 2), it can be seen that within each sales class the average revenue per farm is essentially the same for each profit group, because revenue is used to classify the farms. Consequently the difference in operating earnings can only be attributed to differences in operating expenditures. The difference in operating expenditures between the largest and smallest in each group is an order of magnitude larger than the comparable differences in revenues, being about 50-70% for expenditures and 4-7% for revenues.

In Figure 1 we can see the relative distribution of low, average, and high performers by sales class. Note that the proportion of average performers is smallest in the \$10,000 - 24,999 sales class and increases thereafter, while the proportion of low performers decreases with increasing size until the sales class \$100,000 - \$249,999 after which it increases slightly. The group of high performers is the least variable as a proportion of the total number of farms.

| | |

Off-farm income was examined for a subsample of each of these three groups. Off-farm income is available only for unincorporated taxfilers. Not too surprisingly the group of low performers was also the group with the highest off-farm income for all sales classes. Off-farm income for this group varied from \$21,400 to \$29,400 per operator. The group of average performers varied from \$7,800 to \$22,100, but with only one sales class (\$10,000-\$24,999) greater than \$15,000 in off-farm income. The group of high performers showed a maximum off-farm income of \$19,000, but four out of the other five groups were under \$10,000 in off-farm income.

When operating earnings per dollar of Total Income (Gross Farm Operating Revenues + Total Off-farm Income) are considered the smaller operators (those with Farm Operating Revenues of \$10,000 to \$100,000) behave differently than when off-farm income is not considered. The smaller operators in the group of low performers lose less as a proportion of the total, as do the groups of average operators and high operators. For the operators in sales classes over \$100,000 the impact of off-farm income is minor.

In Table 4 we see that the sum of operating earnings and off-farm income is relatively constant for the sales classes up to \$50,000 no matter which profit group is examined. Above the level of \$50,000 in sales the sum of operating earnings and off-farm income becomes much more variable.

Operating Earnings by Type of Farm - For this part of the analysis, I have used dairy, hogs, and grain and oilseeds farm types.

Operating Earnings for Farms Typed as Dairy - Farms typed as dairy in the 1992 Taxation Data sample exhibited much the same behaviour as those in the entire sample. (See Table 5). The farms in each of the three profit groups behave as do those in the entire Tax sample, where unprofitable farms grow less unprofitable with size, average farms don't change much, and the high farms level off in the higher sales classes.

However, even though each profit group behaves in a similar fashion the distribution of farms amongst these groups is much different. For the Tax sample as a whole low performers constitute about 27% of farms, average about 48%, and the high about 27%. for dairy farms the groups are skewed toward the average and high. Only 6% of dairy farms fall into the low category, while 60% are average and 35% are high.

Operating Earnings for Farms Typed as Hogs - Farms typed as hogs showed the same groupings as in the total sample. Numbers of hog farms were skewed away from the high group compared to the total sample. 25% of hog farms were found in the group of low performers, 61% in the group of average performers and 14% in the group of high performers.

Operating Earnings for Farms Typed as Grains and Oilseeds - Farms typed as grains and oilseeds again exhibited the same groupings as the total sample. However, the distribution amongst the low, average, and high groups was much the same as for the total sample, in contrast to the dairy records which were heavily skewed toward the average and high groups, and also in contrast to hogs where the distribution leaned more heavily toward average.

Table 7: Operating Earnings per \$ of Revenues
Taxation Data Program 1992 - Canada
Farms Typed as Grains and Oilseeds
(numbers of farms in brackets)

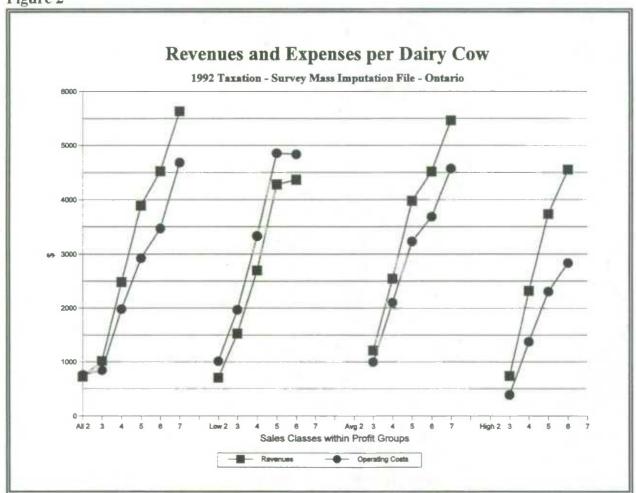

| Sales Classes | All Records | Low Performers | Average Performers | High Performers |
|-----------------------|-------------|-------------------|-----------------------|--------------------|
| \$10,000 to | 0.07 | - 0.41 | 0.14 | 0.56 |
| \$24,999 | (24,910) | (9,575) | (6,745) | (8,405) |
| \$25,000 to | 0.13 | - 0.25 | 0.16 | 0.49 |
| \$49,999 | (21,805) | (6,315) | (9,250) | (6,210) |
| \$50,000 to | 0.18 | - 0.18 | 0.16 | 0.42 (6,440) |
| \$99,999 | (23,555) | (4,185) | (12,915) | |
| \$100,000 to | 0.17 | - 0.15 | 0.16 | 0.40 |
| \$249,999 | (17,105) | (2,070) | (11,430) | (3,605) |

Revenues and Expenses Classified by Numbers of Animals - On an experimental basis, we have used the technique of mass imputation to construct a combined Taxation Data - Survey file that contains both financial and physical variables. A discussion of the technique of mass imputation is beyond the scope of this paper, however it can briefly be said that we integrate the tax and survey files using a linked subgroup of tax and survey records after which we impute the physical values of the linked records to the unlinked portion of the file. The end result is an integrated file with physical variables attached to both linked and unlinked tax records. The financial variables refer to the 1992 Tax year and the physical variables to the end of 1992 for livestock and the 1992-93 crop year for acreages.

I have attached a graph (Figure 2) showing Total Operating Revenues and Operating Costs divided by numbers of dairy cows classified by sales class and profit group for farms in Ontario typed as dairy farms.

Note from Figure 2 that while the group of high performers have revenue per cow as high as or slightly worse than the group of average performers, the operating costs for the group of high performers are always lower than those for the group of average performers. This indicates that while the group of high performers does not have higher revenues per cow than the group of average producers they do manage to better control their costs.

Discussion of Results

The profitability of farms does not appear to depend on their size. In the aggregate medium size farms appear to be the most profitable. The operating earnings of \$0.19 per dollar of operating revenues are found in the \$100,000 to \$250,000 sales class. Splitting farms into the three groups of low, average, and high performers clearly shows that this is not at all the whole story. Amongst low performers, the largest sales class, that of \$500,000 and over in sales, loses the least money in relative terms, while the group of smallest farms loses the most. Within the group of high performers the smallest sales class makes the most at \$0.54 per dollar of revenues. Even the average group doesn't follow exactly the overall trend.

The results from the 1991 Census of Agriculture compare well with the 1992 Taxation sample, indicating that two different sets of estimates from two different universes, farm taxfilers and the Census of Agriculture, show much the same results.

Comparing the results of cost per dollar of Total Operating Revenue with cost per dollar of (Total Operating Revenue + Off-farm Income) shows that farmers adjust total income to compensate for unprofitability.

Off-farm income is highest for those operators in the low performance group, and also for those operators in the lower sales classes, from \$10,000 - \$24,999 and from \$25,000 - \$49,999. These results are intuitively appealing, considering that off-farm income is necessary to maintain an adequate income level, either if the farm business is losing money, or if it is making a high return percentage-wise, but at a low absolute level of net income.

Each farm type divided into the three profitability groups showed much the same characteristics. The principal difference is in the distribution of farms both amongst these groups and by sales class and farm type within the groups.

Conclusion

Size is not a good measure of performance as measured by profitability unless other factors are taken into consideration. By analysing the Taxation sample using three performance groups, it can be seen that both large and small farm businesses can make a profit or lose quantities of money. The interaction of cost and revenues, with the influence of cost being predominant, makes the difference.

Appendix A - Definitions

Note - Most of these definitions are based on those to be found in the Whole Farm Data Base Reference Manual, July 27, 1994.

Farm Type - The type of farm is based on a percentage of agricultural sales. The commodity or commodity group that makes up 51% or more of the sales determines the primary farm type that will be assigned to an individual farm. The Standard Industrial Classification (SIC) four digit codes act as a basis for classifying the farm types. In some cases a fifth digit has been added to the codes to further disaggregate the farm type.

The 11 most commonly used farm types are;

1110 Dairy

1120 Cattle

1130 Hogs

1140 Poultry and Eggs

1190 Livestock Combination

1370 Tobacco

1380 Potatoes

1500 Fruit and Vegetable

1625 Greenhouse and Nursery

9990 Grain and Oilseed

9995 Other Farm Types

Sales Classes - The Whole Farm Data Base makes use of standard revenue classes for producing tables. These classes are:

Class 2 - \$ 10,000 to \$ 24,999

Class 3 - \$ 25,000 to \$ 49,999

Class 4 - \$ 50,000 to \$ 99,999

Class 5 - \$ 100,000 to \$249,999

Class 6 - \$ 250,000 to \$499,999

Class 7 - \$ 500,000 and over

Revenue - refers to the total operating revenues, that is to say all revenues from the sale of agricultural commodities as well as agricultural payments and subsidies. Also included are sales from forest products and interfarm sales. The code for Total Operating Revenues is R2040.

Income Statement - A standard income statement would consist of the following items. the variable names for the taxation records are beside each item, where applicable:

Sales Revenue

Cost of Goods Sold

= Gross Profit

- Operating Expenses

- Depreciation Expenses

= Operating Earnings

- Interest Expense

= Earnings Before Tax

- Income Tax Expense

= Net Income
