## Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

## 1. INTRODUCTION AND SUMMARY

## 1.0) Introduction

This package is designed to enable interested users to aceess and manipulate the microdata file for the sixtecnth cycle of the Gencral Social Survey (GSS) on aging and social support. This survey was conducted from February through December 2002. It contains information on the objectives, methodology and estimation procedures as well as guidelines for relcasing estimates based on the survey. It also gives a description of how to correctly use the microdata files.

Appendix A contains the Approximate Variance Tables with examples of their use. Appendix B contains the questionnaire. The data dictionary for the main microdata file is found in Appendix $C$ and Appendix D contains the record layout. Appendix E contains the data dictionary for the Care Receiving by Respondent File and its record layout is in Appendix F. Appendices G and H respectively contain the data dictionarics and record layout for the Care Giving by Respondent ( 45 to 64) Filc. The data dictionaries and record layout for the Care Giving by Respondent ( 65 and over) File are found in Appendices I and J respectively.

This package is available in machinc-rcadable form.

### 1.1 General Social Survey Cycle 16 - Concepts, Methodology and Data Quality Summary

The information in this section should be used to ensure a clear understanding of the basic concepts that define the data provided in the GSS Cycle 16 Public Use Microdata file, of the underlying methodology of the survey and of key aspects of data quality. This information will provide you with a better understanding of the strengths and limitations of the data, and how they can be effectively uscd and analyzed. The information may be of particular importance to you when making comparisons with data from other surveys or sources of information and in drawing conclusions regarding change over time, differences between geographic areas or differences between sub-groups of the target population. Further detail can be found in the following sections of this document.

### 1.1.1 Data Sources and Methodology

The General Social Survey (GSS) program gathers data on social trends in order to monitor changes in the living conditions and well being of Canadians over time and to provide immediate information on upecific social policy issucs of current or emerging interest. Cycle 16 of the GSS is dedicated to social support for older Canadians, as well as their preparations for retirement and retirement experience.

### 1.1.1.i General Methodology

The target population for Cycle 16 of the GSS was all people aged 45 and over (as of December 31, 2001) in Canada, cxcluding:

1. residents of the Yukon, Northwest Territorics, and Nunavut;
2. full-time residents of institutions;
3. residents living on Indian Reserves, Crown lands or in some remote areas;
4. full-time members of the Canadian Armed Forees.

Respondents were randomly selected from a list of individuals aged 45 years and over who had responded to the Canadian Community Health Survey (CCHS), which collected data in 2001. Computer assisted telephone interviewing (CATI) was used to collect data for GSS-16. The individuals to be interviewed were identified in advance. Thus the collection procedures included those necded to trace people when
they could no longer be reached at their old telephone number. When the person to be interviewed was contacted, they were interviewed in the official language of their choice. Interviews by proxy were allowed.

### 1.1.1.ii Reference Period

Data collection began in February 2002 and continued through to December 2002. The sample was evenly distributed over the 11 months to minimize seasonal variation in the information.

### 1.1.1.iii Estimation

The estimation weights have been adjusted using a raking ratio calibration (post-stratification) technique to match Census based population estimates for strata and for provincial age-sex groups.

### 1.1.2 Concepts and Variables Measured

The survey collects a large number of data items for cach selected respondent as well as some information about each member of the household of the respondent. Some information was also collected for persons providing care to respondents or persons receiving care from the respondents. The public use microdata file documentation includes an annotated list of all data items included in the file as well as the entire questionnaire used. Section 3 of this documentation gives a detailed summary of the content. Here is a brief outline:

Section 1: Activitics of respondent
Scction 2: Health status of respondent
Section 3: Care receiving by respondent
Section 4a: Care giving and assistance by the respondent (45-64)
Scetion 4b: Care giving and assistance by the respondent ( 65 and over)
Section 5: Education and main activity of respondent
Section 6: Retirement planning of respondent
Section 7: Retirement experience of respondent
Section 8: Social contact of respondent
Section 9: Life experiences of respondent
Section 10: Housing characteristics of respondent
Section 11: Other characteristics

### 1.1.3 Data Accuracy

The methodology of this survey has been designed to control errors and to reduce the potential effects of these. However, the results of the survey remain subject to error due to both sampling error and nonsampling error (the difference between the estimates and the true valucs not duc to sampling).

### 1.1.3.i Sampling error

As the data are based on a sample of persons they are subject to sampling error. That is, estimates based on a sample will vary from sample to sample, and typically they will be different from the results that would have been obtained from a complete census. The potential range of this difference has been be estimated for key data and used to produce tables that can be used to estimate the sampling variability of many estimates. These tables along with instructions for, and examples of, their use are found in Appendix A and Section 8 of the Public Use Mierodata File Documentation and User's Guide.

### 1.1.3.ii Non-sampling error

Even a census of the population of interest produces estimates subject to error. While these are called non-sampling errors, estimates from samples still contain errors of this type. Common sources of these errors are imperfect coverage and non-response.

Coverage errors (or imperfect coverage) arise when there are differences between the target population and the surveyed population. Households without telephones represent a part of the target population that was excluded from the surveyed population. To the extent that this excluded population differs from the rest of the target population, the estimates will be biased. In general, since these exclusions are small, one would expect the biases introduced to be small.

To the extent that the non-responding households and persons differ from the rest of the sample, the estimates will be biased. The overall response rate in terms of questionnaires that were complete enough 10) be useful for analysis was close to $84 \%$. Non-response could occur at several stages in this survey. There were two stages of information collection: at the household level and at the individual level. As such, some non-response occurred at the household level, some at the individual level. Non-response also occurs at the level of individual questions so the overall response rate for some questions may be below $84 \%$. For most questions, the response rate was high, with non-response indicated in the data files.

Other types of non-sampling errors can include response erors and processing earors.

## 2. OBJECIIVES OF THE GENERAL SOCIAL SURVEY

The GSS program, established in 1985, conducts telephone surveys across the 10 provinces. The GSS is recognized for its regular collection of cross-sectional data that allows for trend analysis, and its capacity to test and develop new coneepts that address emerging issues.

The two primary objectives of the GSS are:
a) to gather data on social trends in order to monitor changes in the living conditions and well-being of Canadians over time; and
b) to provide immediate information on specific social policy issucs of current or emerging interest.

To meet the stated objectives, the data collected by the GSS are made up of two components: classification and core content. Classification content consists of variables used to delincate population groups and for use in the analysis of core data. Examples of classification variables are age, sex, education, and income. Core content, such as aging and social support, is designed to measure changes in society related to living conditions and well-being and to supply data to inform specific policy issues.

The first (1985) and fifth cycles (1990) of GSS had some content on social support, although health was the main focus for these cycles. With the introduction of the National Population Health Survey in 1994, there was no longer a need to collect data in the health core subject area. Social support was proposed as the new focus for Cycle 11 (1996). The 2002 GSS returns to the topic of social support again, focusing on support for older Canadians and introducing modules on preparations for retirement and retirement experience.

## 3. CONTENT AND SPECIAL FEATURES OF GSS CYCLE 16

The conten of the 2002 questionnare is divided into eleren sections, as follows:

## Section 1: Activities of respondent

These questions are intended to provide a picture of the respondent's self perceived level of physical activity and a measure of other activities. Respondents are also asked about their perceived safety and security.

## Section 2: Health status of respondent

These questions will provide data on the respondent's physical health - general health, injuries, limitations and chronic conditions. Health status information on hearing, sight, speech, and overall mental well-being is also collected.

## Section 3: Care receiving by respondent (aged 65 and older)

This section asks respondents aged 65 and older to provide detailed information on care that is received by seniors both formally and informally because of short-term difficult times or because of long-term health or physical limitations. Questions were also asked about any eare that is needed but not being received and what barriers exist to getting the services that are needed. A detailed roster of all persons providing eare was created and information on each caregiver was collected.

## The types of care were:

Inside Home
Outside Home
Transportation
Personal Care
Other Care
Visiting/Tclephoning
Emotional Support

## Section 4a: Care giving and assivance by the respondent (45-64)

This section asks respondents aged 45 to 64 years to provide detailed information on care that is provided to seniors ( $65+$ ) both formally and informally because of short-term difficult times or because of longterm health or physical limitations. In addition, questions were asked on the impact of care giving on the respondent. A detailed roster of all persons receiving care from the respondent was created and information on each care receiver was collected.

The types of care were:
Inside Home
Outside Home
Transportation
Personal Care
Other Care
To Continue Assistance
Visiting/Telephoning
Emotional Support

## Section th: Care giving and assistance by the respondent (65 and over)

This section asks respondents aged 65 and older to provide detailed information on all care giving activities that they provide. In addition, questions were asked on the impact of care giving on the respondent. A detailed roster of all persons receiving care from the respondent was created and information on each care receiver was collected.

## The types of care were:

Child Care
Inside Home
Outside Home
Transportation
Personal Care
Other Care
Visiting/Telephoning
Emotional Support

## Section 5: Education and main activity of respondent

Respondents are asked questions about their education, main activity and current working experiences in order to identify basic characteristies of respondents. Answers in this section dietate whether the respondent will be asked questions in section 6 and 7. These are standard questions asked across all GSS cyeles.

## Section 6: Retirement planning of respondent

This section is asked of all respondents who have worked at some point since the age ol 30 . The purpose of these questions is to gain a picture of the plans and preparation for retirement.

## Section 7: Retirement experience of respondent

This section is asked of all respondents who have retired at least once even if they are still in the workforce. These questions are intended to increase our understanding of the retirement transition in Canada, to better understand the impact programs and policies have on people's decisions to retire.

## Section 8: Social contact of respondent

This section was designed to help us understand the role that family, friends and social networks play in the giving and receiving of care.

## Section 9: Life experiences of respondent

Respondents are asked if they have experienced certain life events in the past twelve months, such as changing jobs, moving to a new location or death in the family. They are also asked to describe their life satisfaction.

## Section 10: Housing characteristics of respondent

This section is designed to gather information about the respondent's home, including standard GSS questions such as type of dwelling or ownership of the dwelling. New content was added on modifications made and needed to accommodate disability or other physical limitations.

## Section 11: Other characteristics

This section provides background demographic characteristics - birth place, immigration, language, religion, housing arrangements and income. Education and work history information is collected for the respondent's spousc/partner (if living in the respondent's home). These are also standard questions asked across all GSS cycles.

## The database structure

The Cycle 16 GSS comprises 4 related files: The main file contains all the information related to the respondents, which means the content for all sections mentioned above, except for parts of the information found in sections 3, 4a and 4 b that concern care givers or receivers. Each of the three supplementary files contain rosters of persons giving or receiving care, as mentioned above in sections 3 . 4 a and 4 b , as well as information related to those care givers or receivers, such as relationship with the respondent and the type of help given or received. More details are provided in section 7 (ESTIMATION) on how to use these supplementary files.

## 4. SURVEY AND SAMPLE DESIGN

Data for Cycle 16 of the GSS were collected from February to December 2002. The target population is discussed in Section 4.1 and the stratification used in the survey design is outlined in Section 4.2.

### 4.1 Target Population

The target population for Cycle 16 of the GSS was all people aged 45 and over (as of December 31. 2001) in Canada, excluding:

1. residents of the Yukon, Northwest Territories, and Nunavut;
2. full-time residents of institutions;
3. residents living on Indian Reserves, Crown lands or in some remote areas;
4. full-time members of the Canadian Armed Forces.

Respondents were randomly selected from a list of individuals aged 45 years and over who had responded to the Canadian Community Health Survey (CCHS), which collected data in 2001. Computer assisted telephone interviewing (CATI) was used to collect data for GSS-16.

### 4.2 Stratification

Each of the ten provinces was divided into strata and separate samples were selected from each stratum for the CCHS in 200I. These strata were the provincial Health Regions (Morano, M., Lessard, S. and Béland, Y. (2000). Creation of a dual frame for the Canadian Community Health Survey, 2000 Proceedings of the Survey Methods Section, Statistical Society of Canada, pp. 249-254.). The GSS retained these strata for its samples. There were 133 strata in total. Separate samples for the populations 45-54, 55-64, 65-74, and 75 and older were selected from CCHS respondents using an allocation to the CCHS strata that would improve the precision of GSS estimates.

## 5. COLLECTION

Computer assisted telephone interviewing (CATI) was used to collect data for the GSS Cycle 16. Unlike previous GSS cycles, where households were selected through Random Digit Dialling methods, in this cycle the individuals to be intervicwed were identified in advance. Thus the collection procedures included those needed to trace people when they could no longer be reached at their old telephone number. When the person to be interviewed was contacted, they were interviewed in the official language of their choice. Interviews by proxy were allowed. Responding to this survey was voluntary.

The data was collected from February to December 2002. The sample was evenly distributed over the 11 months to minimize seasonal variation in the information. From the 29,678 potential respondents in the GSS Cycle 16 sample, 24,870 usable responses were obtained. This produced a response rate of $83.8 \%$

All interviewing took place using centralized telephone facilities in four of Statistics Canada's regional offices, with calls being made from approximatcly 9:00 a.m. until 9:00 p.m., Monday to Saturday inclusive. The four regional offices were: Halifax, Montreal, Winnipeg and Vancouver. Statisties Canada staff trained interviewers in survey concepts and procedures as well as telephone intervicwing techniques using CATI. The majority of intervicwers had previous experience interviewing for the GSS.

It would be foo lengthy to include all the survey manuals as part of this documentation package. Howerer, more information can be obtained from Statistics Canada (see Section 9).

## 6. PROCESSING

### 6.1 Data Capture

Using CATI, responses to survey questions were entered directly into computers as the interview progressed. The CATI data capture program allowed a valid range of codes for each question and built-in edits, and automatically followed the flow of the questionnaire. The information output by the CATl system was transmitted electronically to head office in Ottawa.

### 6.2 Coding

Several questions allowing write-in responses had this information coded either to new unique cattegories or to a listed catcgory if the write-in information duplicated a listed catcgory. Where possible (c.g., occupation, industry, language, education, country of birth, religion), the coding followed the standard classitication systems as used in the Consus of Population.

### 6.3 Edit and Imputation

All survey records were subjected to computer edits throughout the course of the interview. The CATl system principally edited flow of the questionnaire and identified out of range values. As a result, such problems could be immediately resolved with the respondent. If the interviewer was unable to correctly resolve the detected crrors, it was possible for the interviewer to bypass the edit and forward the data to head office for resolution. All interviewer comments were reviewed and taken into account in head office editing. Head office edits performed the same checks as the CATI system as well as more detailed edits. Due to the nature of the survey, imputation was not appropriate for most items so missing data were usually coded as 'not stated'.

The flow editing carricd out by head office followed a 'top down' strategy, in that whether or not a given question was considered "on path" was based on the response codes to the previous questions. If the response codes to the previous questions indicated that the current question was "on path", the responses, if any, to the current question were retained, though "Don't know" was recoded as 8 ( 98 or 998 , cte.) and refusals were recoded as "Not stated", i.c. 9 ( 99 or 999 , etc.). If a response was missing to the current question, it was coded as "Not stated", i.e. 9 ( 99 or 999 , etc.). If the response codes to the previous questions indicated that the current question was "off path" because the respondent was clearly identified as belonging to a sub-population for which the current question was inappropriate or not of interest, the current question was coded as "Not asked", i.e. 7 ( 97 or 997 .etc.).

### 6.4 Creation of Combined and Derived Variables

Some variables on the filc have been derived from information collected on the questionnaires. In some cases, the derived variables are straightforward and involve collapsing of categories. In other cases, two or more variables have been combined to create a new variable.

### 6.5 Amount of Detail on Microdata File

In order to guard against disclosure, the amount of detail included on this file is less than is available on the master file retained by Statistics Canada. Variables with extreme values have bcen capped and information for some variables has been aggregated into broader classes (e.g., occupation, religion, country of birth). In rare cases, certain variables have been modified in order to protect the confidentiality of respondents. Also, 15 records were suppressed in the microdata file to protect the confidentiality of ${ }^{\prime}$ respondents. For this reason, the file contains information for 24,855 respondents instead of 24.870 persons found in the master file.

## 7. ESTIMATION

When a probability sample is used, as was the case for the GSS, the principle behind estimation is that each person selceted in the sample represents (in addition to himself/hersclf) scveral other persons not in the sample. For example, in a simple random sample of $2 \%$ of the population, cach person in the sample represents 50 persons in the population (himself/herself and 49 others). The number of persons represented by a given respondent is usually known as the weight or weighting factor

One weight is included on the GSS-16 Microdata file:
WGHT_PER: This is the basic weighting factor for analysis at the person level, i.e. to calculate estimates of the number of persons (non-institutionalized and aged 45 and older) having one or scveral given characteristics. WGHT_PER should be used for all cstimates. For example, to estimate the number of persons who would describe their usual state of health as poor, compared to other people their age, the value of WGHT_PER is summed over all records with this characteristic (HS_Q110=5).

GSS Cycle 16 was a survey of individuals and the GSS Cyclc 16 Public Use Microdata file contains questionnaire responses and associated information from 24,855 respondents. Three supplementary filcs contain information on cach of the respondent's care-givers (if respondent was recciving care) or carereceivers (if respondent was giving care). This information relates back to the respondent, so WGHT_PER should be used to produce estimates for the number of respondents with a specific characteristic derived from the care-giver(s) and/or receiver(s).

For example, to derive an estimate of the number of persons receiving care from their daughters, you need to link the main file with the carc-recciving filc using RECID and sum the weights for the respondents that have at least onc record in the care-receiving file with CR_FR_Q100_C $=14$ (using WGHT PER). The respondent may have reported more than one daughter providing care.

Perhaps one is also interested in the average number of daughters from which a recipicnt reccives care. For this one starts by counting the daughters in the care-receiving file for each respondent and then summing these counts, weighted with WGHT_PER. This gives you an cstimatc of the number of recipient-daughter pairs in the population (note that recipients (or respondents) who reccived care from
more than one daughter are represented more than once in this estimate). This number is then divided by the estimate of the number of recipients to get the average number of daughters providing care to a recipient. The same principles can be applicd when using the 2 other supplementary files (care giving files 45-64 and 65 and over).

The care giving and care receiving files should be used with caution because each record on these files does not represent a person, but rather a relationship between two pcople. The relationship is between the respondent and a care giver, or between the respondent and a care receiver. The estimate obtained by using WGHT_PER and the number of earcgivers for the respondent is an estimate of the total number of care giving relationships in the population. When a caregiver provides eare for more than one person the caregiver is represented by more than onc relationship in this estimate. Similarly people who receive care from more than one earegiver will be represented by more than one relationship in the estimate. Hence there are more relationships than either givers or receivers. The supplementary files can be used to describe characteristics of the relationships that they represent or to derive characteristics of the respondent.

GSS Cyele 16 was not designed to be a survey of households, so questions such as DOR_Q110: "In what type of dwelling are you now living?" should be used to estimate the number of persons (aged 45 and older) who live in a particular type of dwelling (rather than the number of dwellings of a given type). For example, to estimate the number of persons who live in low-rise or high-rise apartments, WGHT_PER should be summed over all respondents with DWELC_C $=2$ (DWELC_C is derived from DOR_QI10).

### 7.1 The Weighting Process

The objective of the weighting process is to assign weights that improve the estimates made from the survey. The choice of the weighting factor to assign to each respondent and its derivation is not a simple or straightforward one. A natural choice for probability samples is the inverse of the probability of selection, but even this gencrally needs to be adjusted for non-responsc. For this cycle of the GSS, an initial weight (reflecting the probability of selection from the CCHS, adjusted for CCHS non-response) was further refined to arrive at a final weight that makes the weighted file more representative of the target population.

## 1) Initial GSS Weight

The initial GSS weight is based on the probability with which the GSS selected respondents from the CCHS and the probability that the CCHS selected the respondent (adjusted for CCHS non-response). This weight was cateulated independently for each stratum as follows:

Total number of CCHS respondents
in cach stratum
Non-response adjusted CCHS weight
Number of CCHS respondents selected for the GSS in each stratum

## 2) Tracing Adjustment

Weights for persons who were successfully traced during data collection were adjusted to represent persons who were not traced. This was done by fitting a model for the probability that a person could be traced, based on demographic variables available from the CCHS. The basic weights were adjusted by multiplying by the inverse of the probability of being traced predicted by the model.

Only the traced cases were used in the subsequent weighting steps.

## 3) Non-Response Adjustment

Weights for responding persons were adjusted to represent non-responding persons. This was done independently within each province and age group (45-54, 55-64, 65-74, and $75+$ ). The traced weights were adjusted by multiplying by the following factor:

> Total of the traced weights of all persons in each
> province-age group

Factor $1=$
Total of the traced weights of responding persons in each province-age group

This produces the basic person weight $=$ Traced Weight * Factor 1. This reflects the probability of selection of the respondent, adjusted for non-tracing and non-response.

Only the responding cases were used in the subsequent weighting steps.

## 4) Adjustment of Person Weight to External Totals

The basic person weights were then adjusted using a raking ratio procedure. This procedure ensures that the weighted sample file is representative of the population with respect to certain characteristics. As used by the GSS, it ensures that weighted estimates of the size of certain subgroups of the population (the poststrata) produced from the survey agree with external reference totals for these population sizes. Two sets of external references were used for this survey, population sizes for geographically defined post-strata and for age-sex groups by province. To the extent that the characteristics we measure are correlated with age-sex groups and with the geographic post-strata, this adjustment or calibration of the weights will improve the accuracy of estimates.

## 4a) Geographic Post-Stratum Adjustment

An adjustment was made to the person weights of records within each post-stratum in order to make GSS population estimates consistent with the official population estimates produced by Statistics Canada's Demography Division. This was done by multiplying the person weight for each record within the stratum by the following ratio:

Official population estimate
for the post-stratum
Sum of the person weights for the post-stratum

## 4b) Province - Age - Sex Adjusiment

The next weighting step was to adjust the weights to agree with projected province-age-sex population distributions. Official population estimates were obtained for males and females within the following ten age groups:

| $45-49$, | $50-54$, | $55-59$, |  |
| :--- | :--- | :--- | :--- |
| $60-64$, | $65-69$, | $70-74$, |  |
| $75-79$, | $80-84$, | $85-89$, | $90+$ |

For each of the resulting province-age-sex groups, the person weights for records within the group were adjusted by multiplying by the following ratio:

Official population estimate for the province-age-sex group

Sum of the person weights of records for the province-age-sex group

When sample sizes were small, two or more age groups for the same province and sex were combined before this adjustment was made.

## 4c) Raking Ratio Adjustments

The weights of each respondent were adjusted several times using a raking ratio procedure. This procedure ensured that estimates produced for both geographic post-stratum totals and province-age-sex totals would agree with the official population estimates. This adjustment was made by repeating steps ta) and 4b) of the weighting procedures until each repectition of the step made a minimal adjustment to the weights.

## 5) Final Person Weight

The weight produced at the end of 4) is the thal person weight WGHT_PER placed on the Main File.

### 7.2 Weighting Policy

Users are cautioned against releasing unweighted tables or performing any analysis based on unweighted survey results. As was discussed in Scction 7.1, there were several weight adjustments performed that depended on the province, stratum, age and sex of the respondent. Sampling rates as well as non-response rates varied significantly from province to province, and non-response rates varied with demographic characteristics. For example, the sampling fraction for younger respondents to this survey was lower than for older respondents, which would tend to make them relatively under-represented in the unweighted sample. This is supported by the data. In the responding sample, $11 \%$ were males between the ages of 45 and 54 , while in the overall population sampled, approximatcly $20 \%$ were malcs between 45 and 54 . Therefore, it is clear that unweighted sample counts cannot be considered to be representative of the survey target population.

Contact was made or attempted with 29,678 respondents during the survey. From these respondents, 24,870 usable responses were obtained, for a response rate of $84 \%$ (when it is assumed that all of the respondents for which there was no response were "in scope", i.e., were still living in Canada). The distribution of types of non-response and response is shown in the table below:

| Total sample of persons | 29,678 | $100 \%$ |
| :--- | ---: | :--- |
| 1 Persons not traced | 2,830 | $9.5 \%$ |
| 2 Non-response | 1,978 | $6.7 \%$ |
| 3 Responses | 24,870 | $83.8 \%$ |

To protect the confidentiality of respondents, 15 records were suppressed in the public use microdata file. For this reason, the file contains information for 24,855 respondents instead of the 24,870 persons who provided responses for the survey (and who are all found in the master file).

### 7.3 Types of Estimates

As previously mentioned, a basic person weight has been assigned to each sampled individual and, as: described in section 7.1, these weights have been adjusted to reflect the age and sex composition of the various provincial populations as estimated by Statistics Canada.

$$
\begin{aligned}
\sum_{i=1}^{24,855} \text { WGHT PER } & =11,139983 \\
& =\quad \begin{array}{l}
\text { an cstimate of the number of persons } 45 \text { years of age and older in } \\
\text { the population. }
\end{array}
\end{aligned}
$$

Two types of 'simple' estimates are possible from the results of the General Social Survey. These are qualitative estimates (estimates of counts or proportions of peoplc possessing certain qualitics or characteristics) and quantitative estimates involving quantitics or averages. More complex estimation and analyses are covered in Section 7.4.

### 7.3.1 Qualitative Estimates

It should be kept in mind that the target population for the GSS was non-institutionalized persons 45 years of age or older, living in the ten provinces. Qualitative estimates are estimates of the number or proportion of this target population possessing certain characteristics. The number of people $(1,672,123)$ whose highest level of education was 'High school diploma' (EDU5 $=4$ ) is an example of this kind of estimate. These estimates are readily obtained by summing the person weights (WGHT PER) of the records possessing the characteristic of interest.

This estimate does not, however, adjust for non-response to the question in any way. If we make the assumption that those who either refused to answer the question or who responded 'don't know' have the same distribution as those who responded, then an adjusted estimate can be made. To do this, ignore the respondents with a "Not stated" or 'Don't know' answer to question EDU5 and estimate the desired proportion of the target population using only the remaining respondents. This estimated proportion is the ratio of the sum of the weights for those respondents who answered that their highest level of education obtained was 'High school diploma' (EDU5 $=4)(1,672,123)$ to the sum of the weights for those respondents for whom the highest level of education obtained is known (EDU5 $=1,2,3,4$, or 5 ) (10,940,786). This proportion is then multiplied by the size of the target population to produce the final estimate:

$$
1,702,567=11,139,983 \times \quad \frac{1,672,123}{10,940,786}
$$

When the proportion of responses that are 'don't know' or 'refused' is high, the differences between the two estimates will be large. A similar adjustment for non-response only could be done by ignoring the 'Not stated' respondents only. These adjustments are not necessary, but often produce more useful estimates. Without such an adjustment the estimates divide the population into those with a characteristic, those without the characteristic, and those for whom the questionnaire could not determine the characteristic. With the adjustment, one divides the population into those with and those without the characteristic.

Another example of a qualitative estimate is the number of people $(2,838,309)$ whose answer to the religious attendance question would be "At least once a week" (RELIGATT $=1$ ). Again this estimate does not adjust for non-response to the question in any way. The adjustment is done and a final estimate produced by following the same method used in the previous example. We end up with the final estimate being:

$$
2,853,221=11,139,983 \times \frac{2,838,309}{11081.761}
$$

### 7.3.2 Quantitative Estimates

Some variables on the General Social Survey microdata files are quantitative in nature (e.g. age, number of weeks worked at a job or business in the past 12 months). From these variables, it is possible to obtain such estimates as the average number of weeks worked in the last 12 months. These quantitative estimates are of the following ratio form:

Estimate $($ average $)=X / Y$
The numerator ( X ) is a quantitative estimate of the total of the variable of interest (for example, the number of weeks worked in the past 12 months) for a given subpopulation (for example, males in Ontario
who were employed in the past 12 months). In this example, X would be calculated by multiplying the person weight (WGHT_PER) by the variable of interest (WKWE) when it is known, $1<=$ WKWE $<=52$, (i.e. not equal to ' 97 ' $^{\prime},^{\prime} 98^{\prime}$ or ' $99^{\prime}$ ), and summing this product over all records for males in Ontario who were employed i.e. $\mathrm{SEX}=1$ and $\mathrm{PRV}=35$ and ( $1<=\mathrm{WKWE}<=52$ ), which yields $55,303,097$ (weeks).

The denominator $(\mathrm{Y})$ is the qualitative estimate of the number of persons within that subpopulation (males in Ontario who were employed in the past 12 months for whom we have a valid number of weeks). In this example, Y would be calculated by summing the person weight (WGHT_PER) over all male respondents in Ontario with $1<=$ WKWE $<=52$, yielding 1,165,514 (persons).

The two estimates X and Y are derived independently and then divided to provide the quantitative estimate. The average number of weeks is then calculated to be:

$$
\frac{55,303,097}{1,165,513}=47.4 \text { (weeks per person) }
$$

### 7.4 Guidelines for Analysis

As is detailed in Section 4 of this document, the respondents from the GSS do not form a simple random sample of the target population. Instead, the survey had a complex design, with stratification and multiple stages of selection, and uncqual probabilities of selection of respondents. Using data from such complex surveys presents problems to analysts because the survey design and the selection probabilites affect the estimation and variance calculation procedures that should be used.

The GSS used a stratified design, with signifieant differences in sampling fractions between strata. Thus, some areas are over-represented in the sample (relative to their populations) while some other areas are relatively under-represented; this means that the unweighted sample is not representative of the target population, even if there were no non-response. Non-response rates may vary by demographic group (sce section 7.2), making the unweighted sample even less representative.

The survey weights must be used when producing estimates or performing analyses in order to account as much as possible for the geographic over- or under-representation and for the over- or underrepresentation of age-sex groups in the unweighted filc. While many analysis procedures found in statistical packages allow weights to be used, the meaning or definition of the weight in these procedures often differs from that which is appropriate in a sample survey framework, with the result that, while in many eases the estimates produced by the packages are correct, the variances that are calculated may be almost meaningless.

For many analysis techniques (for example linear regression, logistic regression, estimation of rates and proportions, and analysis of variance), a method exists that can make the variances calculated by the standard packages more meaningful. If the weights of the respondents, or of the subset of the respondents being used in the analysis, are rescaled so that the average weight is one (1), then the variances produced by the standard packages will be more reasonable. They still will not take into account the stratification and clustering of the sample's design, but they will take into account the unequal probabilities of selection. This rescaling can be accomplished by dividing each weight by the overall average weight before the analysis is conducted.

For an analysis of all respondents who were living with a common-law partner, the following steps are required:

- Select all respondents from the file who were living with a common-law partner (PRTYPEC=2);
- Calculate the Average Weight of WGHT_PER for these records;
- For each of these respondents calculate a "working" weight equal to WGHT_PER / Average Weight;
- Perform the analysis for these respondents using the "working" weight.

Section 8 describes sampling variability and data reliability in more detail and Appendix A provides a series of tables that can be used to estimate the sampling variability of many qualitative estimates of totals and proportions.

## 8. RELEASE GUIDELINES AND DATA RELIABILITY

It is important for users to become familiar with the contents of this section before publishing or otherwise releasing any estimates derived from the (ieneral Social Survey microdata files.

This section of the documentation provides guidelines to be followed by usirs. With the aid of these guidelines, users of the microdata files should be able to produce tligures consistent with those produced by Statistics Canada and in conformance with the established guidelines for rounding and release. The gnidelines can be broken into four broad sections: Minimum Sample Sizes for Estimates; Sampling Variability Policy; Sampling Variability Estimation; and Rounding Policy.

## 8. 1 Minimum Sample Size for Estimates

Users should determine the number of records on the microdata file that contribute to the calculation of a given estimate. This number should be at least 15 . When the number of contributors to the weighted estimate is less than this, the weighted estimate should generally not be relcased regardless of the value of the Approximate Coefficient of Variation. If it is, it should be with great caution and the insufficient number of contributors associated with the estimate should be prominently noted.

### 8.2 Sampling Variability Guidelines

The estimates derived from this survey are based on a sample of households. Somewhat different figures might have been obtained if a complete census had been taken using the same questionnaire, interviewers, superyisors, processing methods, etc. The difference between the estimates obtained from the sample and the results from a complete count taken under similar conditions is called the sampling error of the estimate.

Errors which are not related to sampling may occur at almost every phase of a survey operation. Interviewers may misunderstand instructions, respondents may make errors in answering questions, the answers may be incorrectly entered into the CATI system, and errors may be introduced in the processing and tabulation of the data. These are all examples of non-sampling errors.

Over a large number of observations, randomly occurring errors will have little effect on estimates derived from the survey. However, errors occurring systematically will contribute to biases in the survey estimates. Considerable time and effort was made to reduce non-sampling errors in the survey. Quality atsurance measures were implemented at each step of the data collection and processing cycle to monitor the quality of the data. These measures included the use of highly skilled interviewers, extensive training of interviewers with respect to the survey procedures and questionnaire, observation of interviewers to
detect problems of questionnaire design or misunderstanding of instructions, procedures to ensure that data capture errors were minimized and coding and edit quality checks to verify the processing logic.

### 8.2.1 Non-sampling Errors

A major source of non-sampling errors in surveys is the effect of non-response on the survey results. The extent of non-response varies from partial non-response (failure to answer just one or a few questions) to total non-response. Total non-response occurred because the interviewer was unable to contact the selected respondent, the respondent was unable to provide the information (perhaps due to a language problem), or the respondent refused to participate in the survey. Total non-response was handled by adjusting the weight of households who responded to the survey to compensate for those who did not respond.

In most cases, partial non-response to the survey occurred when the respondent did not understand or misinterpreted a question, refused to answer a question, or could not recall the requested information. When there was partial non-response, the GSS did not impute responses, but instead left the answer as 'Not stated".

## 8.2.i Sampling Errors

Since it is an unavoidable fact that estimates trom a sample survey are subject to sampling crror, sound statistical practice calls for researchers to provide users with some indication of the magnitude of this sampling error.

Although the exact sampling error of an estimate, as defined above, cannot be measured from sample results alone, it is possible to estimate a statistical measure of sampling error, the standard error, from the sample data. Using the standard error, confidence intervals for estimates (ignoring the effects of nonsampling error) may be obtained under the assumption that the estimates are normally distributed about the true population valuc. The chances are about 68 out of 100 that the difference between a sample estimate and the true population value is less than one standard error, about 95 out of 100 that the difference is less than two standard errors, and it is virtually certain that the difference is less than three standard crrors.

Since the absolute size of the sampling enor of an estimate is often less important than its relative size (relative to the estimate itself) the standard error is not always the best measure of sampling error. For example, a standard error of 10 for an estimate of 20 would generally be taken as indicating that the estimate is a poor one, while the same standard error for an estimate of 1.000 would generally indicate a good estimate. For this reason the size of the sampling error is often expressed relative to the size of the estimate, as the coefficient of variation (c.v.). The coefficient of variation of an estimate is obtained by dividing the standard error of the estimate by the estimate itself, and the resulting fraction is usually expressed as a percentage. In the above example, the first estimate has a cer. of $500^{\circ} \mathrm{B}(1020)$, while the second has a c.v. of $1 \%(10 / 1,000)$.

In order to provide a means of assessing the quality of many estimates, Statistics Canada has produced a set of Approximate Sampling Variability Tables for the GSS. These tables can be used to obtain approximate coefficients of variation for categorical-type estimates and proportions. More precise estimates of the sampling variability of cstimates can be produced with the bootstrap method using bootstrap weights that have been created for this survey. Bootstrap weights are available at Statistics Canada's Research Data Centres, but are not available for GSS-16 as part of the microdata file. See Scction 8.3 for more details.

## Guidelines for Release of Estimates

When considering releasing and/or publishing an estimate from the microdata file, users should consult the table below and follow the guideline that matches the coefficient of variation of the estimate.

| Type of Estimate | Coefficient of Variation | Guidelines for Release |
| :---: | :---: | :---: |
| 1. With Moderate Sampling Variablity | 0.0\% 10 16.5\% | Estimates can be considered for general unrestricted release. No special notation is required. |
| 2. With High Sampling Variahility | 16.6\% $6035.3 \%$ | Essimates can be considered for general unresiricted release but should be accompanied by a waming cautioning users of the high sampling variability associated with the estimates. |
| 3. With Very High Sampling Variability | 33.4\% or over | Estimates should generally not be released, but when they are it should be with great caution and the very high sampling variability associated with the estimate should be prominently noted. |

Note: The sampling variability guidelines should be applied to rounded estimates.

### 8.3 Estimates of Variance

As the data are based on a sample of persons they are subject to sampling error. That is, estimates based on a sample will vary from sample to sample, and typically they will be different from the results that would have been obtained from a complete census.

The potential range of this difference has been estimated for key data and used to produce tahles that can be used to estimate the sampling variability of many estimates.

### 8.3.1 Sampling Variability for Qualitative Estimates

Derivation of the sampling variability of each of the qualitative estimates that could be generated from the survey would be an extremety costly procedure, and for most users, an unnecessary one. Consequently, approximate measures of sampling variability, in the form of tables, have been developed for use and are included in APPENDIX A ("Approximate Variance Tables"). These tables were produced using the cocfficient of variation formula based on a simple random sample. Since the design of Cycle 16 of the (iencral Social Survey was not a simple random sample, a factor ealled the Design Effect has been introduced into the variance formula.

The Design Effect of an estimate is the actual variance of the estimate (taking into account the sample design that was used) divided by the variance that would have resulted if the estimate had been derived from a simple random sample of the same size. The Design Effect used to produce the Approximate Variance Tables has been determined by first estimating Design Effects for a wide range of characteristics and then choosing among these a conservative value which will not give a false impression of high precision. These Design Effects are specified in the table that follows.

## Design Effects

## Population

| Geographic Area | $45+$ | $\mathbf{4 5 - 6 4}$ | $65+$ |
| :--- | :--- | :--- | :--- |
| CANADA | 1.80 | 1.62 | 1.90 |
| NEWFOUNDLAND | 1.18 | 1.05 | 1.35 |
| PRINCE EDWARD ISLAND | 1.32 | 1.16 | 1.43 |
| NOVA SCOTIA | 1.31 | 1.13 | 1.58 |
| NEW BRUNSWICK | 1.26 | 1.24 | 1.39 |
| QUEBEC | 1.75 | 1.53 | 1.95 |
| ONTARIO | 1.80 | 1.46 | 2.01 |
| MANITOBA | 1.42 | 1.23 | 1.55 |
| SASKATCHEWAN | 1.29 | 1.22 | 1.35 |
| ALBERTA | 1.48 | 1.37 | 1.60 |
| BRITISH COLUMBIA | 1.45 | 1.28 | 1.49 |
| ATLANTIC REGION | 1.43 | 1.27 | 1.56 |
| PRAIRIEREGION | 1.59 | 1.53 | 1.58 |

Approximate variance tables for estimates using WGHT PER are provided at the Canada and provincial levels as well as for the Atlantic and Prairie Regions.

It should be noted that all coefficients of variation in these tables are approximate and therefore unofficial. However, more precise estimates of the sampling coefficients of variation for specific variables may be obtained using "bootstrap" weights and associated programs (this requires access to information not included as part of the microdata file but available in the RDC's). The types of estimates supported include 'aggregates' or 'totals', proportions, ratios, differences between 'aggregates' or 'totals'. as well as more sophisticated types of analyses such as estimates of coefficients from linear regressions and logistic regressions, among others.

The use of variable-specific variance calculation instead of the table-based approximations may allow users to feel more certain of the quality of their estimates, especially those with cocfficients of variation estimated from the tables in the "Very High Sampling Variability" range (see the guidelines regarding the relcase of the survey estimates on preceding pages).

### 8.3.2 Sampling Variability for Quantitative Estimates

Approximate variances for quantitative variables cannot be as conveniently summarized. As a general rule, however, the coefficient of variation of a quantitative total will be larger than the cocfficient of variation of the corresponding qualitative estimate (e.g., the number of persons contributing to the quantitative estimate). If the corresponding qualitative estimate has high sampling variability, then the quantitative total will in gencral have high sampling variability as well.

### 8.3.3 Bootstrap Method for Variance Estimation

In order to determine the quality of the estimate and to calculate the CV, the standard deviation must be calculated. Confidence intervals also require the standard deviation of the estimate. The GSS uses a multi-stage survey design and calibration, which means that there is no simple formula that ean be used to calculate variance estimates. Therefore, an approximate method was needed. The bootstrap method is used because the sample design and calibration needs to be taken into account when calculating varianee estimates. The bootstrap method does this, and with the use of the Bootvar program, diseussed in the next subsection, is a method that is fairly easy for users with aceess to the bootstrap weights.

The GSS uses the mean bootstrap method (Yung, W. (1997) Variance estimation for public use mierodata files. Symposium 97, New Directions in Surveys and Censuses: proceedings, pp. 91-95. Statisties Canada, Ottawa).

Independently, in each stratum, a simple random sample of ( $\mathrm{n}-1$ ) of the n units in the sample is selected with replacement. Note that since the selection is with replacement, a unit may be chosen more than onee. This step is repeated R times to form R bootstrap samples, An average initial bootstrap weight based on the R samples is calculated for each sample unit in the stratum. The entire process (selecting simple random samples, recalculating weights for each stratum) is repeated $B$ times, where $B$ is large, yielding $B$ different initial bootstrap weights. The GSS typically uses $\mathrm{R}=25$ and $\mathrm{B}=200$, to produce 200 bootstrap weights.

These weights are then adjusted according to the same weighting process as the regular weights: non response adjustment, calibration and so on. The end result is 200 final bootstrap weights for each unit in the sample. The variation among the 200 possible estimates based on the 200 bootstrap weights is related to the variance of the estimator based on the regular weights and can be used to estimate it.

There are a number of reasons why a user may need to calculate the coefficient of variation of estimates with the bootstrap method. A few are given below.

First, if a user desires estimates at a geographie level smaller than the province (for example, at the urban/rural level), then the Approximate Variance tables provided are not adequate. Coefficients of variation of these estimates may be obtained using "domain" estimation techniques through the Bootstrap varianee program. Second, should a user require more sophistieated analyses such as estimates of coefficients from lincar regressions or logistic regressions, the Approximate Variance tables will not provide correct associated coefficients of variation. Although some standard statistical packages allow sampling weights to be incorporated in the analyses, the variances that are produced often do not take into account the design properly and/or calibration of the weights, whereas the Bootstrap variance program does so. Third, for estimates of quantitative variables, separate tables are required to determine their sampling error. Since most of the variables for the Gencral Social Survey are eategorical in nature, this has not been done. Thus, users wishing to obtain coefficients of variation for quantitative variables must do so through the Bootstrap variance program.

The Random Digit Dialing sample design of most GSS cycles allows the release of bootstrap weights on the Public Use Microdata File without compromising confidentiality. In contrast, the design of GSS-16 does not atlow the release of bootstrap weights.

### 8.3.4 Bootvar Program for Variance Estimation

Statistics Canada has developed a program that can perform bootstrap variance estimation: the Bootvar program.

The Bootvar program is available in both SAS and SPSS formats. It is made up of macros that compute variances for totals, ratios, differences between ratios and for linear and logistic regression.

The Bootvar program and the bootstrap weights are available to researchers using the GSS-16 data in the Statistics Canada Research Data Centres.

### 8.4 Rounding

In order that estimates produced from the General Social Survey microdata files correspond to those produced by Statistics Canada, users are urged to adhere to the following guidelines regarding the rounding of such estimates. It may be misleading to relcase unrounded estimates, as they imply greater precision than actually exists.

### 8.4.1 Rounding Guidelines

1) Estimates of totals in the main body of a statistical table shouk be rounded to the nearest thousand using the normal rounding technique (see detimition in Section 8.4.2).
2) Marginal subtotals and totals in statstical tables are to be derived from their corresponding unrounded components and then are to be rounded themselves to the nearest thousand units using normal rounding
3) Averages, proportions, rates and percentages are to be computed from unrounded components and then are to be rounded themselves to one decimal using normal rounding
4) Sums and differences of aggregates and ratios are to be derived from corresponding unrounded components and then rounded to the nearest thousand units or the nearest one decimal using normal rounding.
5) In instances where, due to technicat or other limitations, a different rounding technique is used, resulting in estimates different from Statistics Canada estimates, users are encouraged to note the reason for such differences in the released document.

### 8.4.2 Normal Rounding

In normal rounding, if the first or only digit to be dropped is 0 to 4 , the last digit to be retained is not changed. If the first or only digit to be dropped is 5 to 9 , the last digit to be retained is raised by one. For example, the number 8499 rounded to thousands would be 8000 and the number 8500 rounded to thousands would be 9000 .

## 9. ADDITIONAL INFORMATION

Additional information about this survey can be obtained from the individuals listed below. Data from the survey are available through published reports, special request tabulations, and this microdata file. The microdata file is available from the Social and Aboriginal Statistics Division of Statistics Canada at a cost of $\$ 2,140$. Special tabulations can be obtained at a cost that reflects the resources that are required to produce them.

## APPENDIX A

## Approximate Variance Tables

## APPROXIMATE VARIANCE TABLES

By using the Approximate Variance Tables and the following rules, users should be able to determine approximate coefficients of variation for qualitative* estimates or combinations of such estimates such as percentages, ratios, differences between totals and differences between ratios. Note that these tables are not appropriate for determining variances for quantitative* estimates.

There are three tables for each geographic area, one table for each of these populations:

- Population aged 45 years and over;
- Population aged 45 to 64 ;
- Population aged 65 and over.

The geographic areas are Canada, the ten provinces and the Atlantic and Prairie Regions.
As noted in 8.2 , estimates having cv's of more than $33.3 \%$ are not releasable. In addition, as mentioned in 8.1, each estimate should be derived from at least 15 respondents in order to be released, regardless of the approximate coefficient of variation.

[^0]
## Rules for Obtaining Approximate Variances

The following rules should enable the user to determine the approximate coefficients of variation from the Approximate Variance Tables for estimates of the number, proportion or percentage of the surveyed population possessing a certain characteristic and for ratios and differences between estimates.

As noted in Section 8.1, all estimates should contain at least the minimum number of contributors in order to be released, regardless of the Approximate Coefficient of Variation.

## Rule 1: Estimates of Numbers Possessing a Characteristic (Aggregates)

The coefficient of variation (cv) depends only on the size of the estimated aggregate itself. In the appropriate Approximate Variance Table, locate the cstimated aggregate in the left-most column of the table (headed "Numerator of Percentage") and follow the asterisks across to the first figure encountered. This figure is the estimated coefficient of variation.

## Example 1:

A user estimates that in Canada 958,652 females aged 45 vears and over have obtained a 'High school diploma' as the highest level of education $(E D U 5=4)$. How does the user determine the approximate coefficient of variation for this estimate?

Refer to the approximate variance table for Canada level estimates for the age group 45 and over. The estimated aggregate does not appear in the lefi-most column 'the 'Numerator of Percentage' column), so it is necessary to use the closest figure, namely 1,000,000. The coefficient of variation for an estimated aggregate is found by referring to the first non-asterisk entry for that row, in this case 2.7. This cv falls within the range of cv's for 'Unqualified' estimates (i.e. 0.0.0 $-16.5 \%$, Section 8.2.i) allowing the estimate to be released without restriction.

## Rule 2: Estimates of Percentages or Proportions Possessing a Characteristic

The coefficient of variation of an estimated percentage or proportion depends on both the size of the percentage or proportion and the size of the total upon which the percentage is based. Estimated percentages or proportions are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. (Note that in the tables the $\mathrm{cv}^{\prime} \mathrm{s}$ decline in value reading from left to right).

When the percentage or proportion is based upon the total population of the geographic area covered by the table, the ev of the percentage or proportion is the same as the cv of the numerator of the percentage. In this case, Rule 1 can be used.

When the percentage or proportion is based upon a subset of the total population (e.g., those in a particular age-sex group), reference should be made to the percentage (across the top of the table) and to the numerator of the percentage or proportion (down the left side of the table). The intersection of the appropriate row and column gives the coefficient of variation.

## Example 2:

A user estimates that in Canada, 16.4\% of females aged 45 vears and over have obtained a 'High school diploma' as the highest level of education. This is the expression of the estimate obtained in Example 1 as a percentage of all females aged 45 vears and over in Canada. How does the user determine the approximate coefficient of variation for this estimate?

Refer to the approximate variance table for Canada level estimates for the age group 45 and over. Because the estimate is a percentage, which is based on a subset of the population covered by the table, it is necessary to use both the percentage ( $16.4 \%$ ) and the numerator portion of the percentage $(958,652)$ to determine the approximate coefficient of variation. Since the numerator does not appear in the left-most column the 'Numerator of Percentage' column), it is necessary to use the figure closest to it, namety 1,000,000. Similarly, the percentage estimate does not appear among the column headings, so it is necessary to use the figure closest to it, namely $15.0 \%$. The figure at the imtersection of the row and column selected, namely $2.6 \%$, is the coefficient of variation. This ov falls within the range of cv's for 'Unqualified' estimates (i.e. $0.0 \%-16.5 \%$, Section 8.2.i) allowing the estimate to be released without restriction.

## Rule 3: Ratios

In the case where the numerator is a subset of the denominator, the ratio should be converted to a percentage and Rule 2 applied. This would apply, for example, to the case where the denominator is the number of males and the numerator is the number of males who obtained a 'High school diploma'.

In the case where the numerator is not a subset of the denominator, the coefficient of variation of the ratio of two estimates is approximately equal to the square root of the sum of squares of each coefficient of variation considered separately. That is, the standard deviation of a ratio
$\mathrm{R}=\mathrm{X} / \mathrm{Y}$
is: $\quad \operatorname{sd}(\mathrm{R})=\mathrm{R}^{*}\left(\mathrm{cv}(\mathrm{X})^{2}+\operatorname{cv}(\mathrm{Y})^{2}\right)^{1 / 2}$

The coefficient of variation of $R$ is approximately:
$c v(R)=s d(R) / R$

$$
=\left(\operatorname{cv}(\mathrm{X})^{2}+\operatorname{cv}(\mathrm{Y})^{2}\right)^{12}
$$

This formula will tend to overstate the error if X and Y are positively correlated and understate the error if X and Y are negatively correlated.

## Example 3:

A user estimates that in Canada, among males between 50 and 64 years of age, 352,167 have obtained a 'High school diploma' as the highest level of education and among females between 50 and 64 years of age, 417,653 over have obtained a 'High school diploma' as the highest level of education. The user is interested in the ratio of males aged 50 to 64 who obtained a 'High school diploma' versus females aged 50 to 64 who have ohtained a 'High school diploma'. How does the user determine the approximate coefficient of variation for this ratio estimate?

The numerator of the ratio estimate is 352,167 (X). Using Rule 1 (refer to Example 1) and the Canada table for age group 45-64, the coefficient of variation for this estimate is determined to be $5.2 \%(\mathrm{cv}(X))$. The denominator of the ratio estimate is 417,653 (Y). Again using Rule $l$, the coefficient of variation is determined to be $4.7 \%(\mathrm{cv}(Y))$. Using Rule 3, the coefficient of variation of the ratio estimate is:

$$
\begin{aligned}
c v & \left.=0.052^{2}+0.047^{2}\right)^{3} \\
& =0.070
\end{aligned}
$$

Therefore at the Canada tevel, the ratto of males aged 501064 who obtained a 'High school diploma' as the highest level of education versus females aged 50 to 64 who have obtained a 'High school diploma' as the highest level of education is 352,167/417,653 or . 84 to 1. The coefficient of variation of this estimate is $7.0 \%$ and so the estimate can be released without restrictien.

## Rule 4: Differences Between Totals or Percentages

The standard deviation of a difference between two estimates is approximately equal to the square root of the sum of squares of each standard deviation considered separately. That is, the standard deviation of a difference:
$d=X-Y$
is : $\quad \quad \quad \operatorname{dd}(\mathrm{d})=\left((\mathrm{X} * \operatorname{cv}(\mathrm{X}))^{2}+(\mathrm{Y} * \operatorname{cv}(\mathrm{Y}))^{2}\right)^{1 / 2}$
The coefficient of variation of $d$ is approximately:
Cl(d) $=s d(d) / d$
This formula is aceurate for the difference between separate and uncortclated characteristics but is only approximate otherwise.

## Example 4:

A nset estmanes that in Canada, among those between 50 and 64 vears of age. $14.1 \%$ 0) of males have obtained a 'High school diploma' as the highest level of education and $16.3 \%$ (2) of females have obtained a 'High school diploma' as the highest level of education. The user is interested in the difference between these wo estimates. How does the user determine the approximate coefficient of variation for the estimate of the difference?

Using Rute 2. The coefficient of variation for the mate extinate is $4.9 \%$. The coefficien of wation

The difference between the estimates is $2.2 \%$. Using Rule 4 , the standard deviation of the difference between the estimates is:

$$
\begin{aligned}
s d \quad & =\left((0.141 \times 0.049)^{2}+(0.163 \times 0.046)^{2}\right)^{0.5} \\
& =0.010
\end{aligned}
$$

and the coefficient of variation is:
0.010
$\mathrm{Cv}=\frac{\ldots------}{0.022}$
$=0.46$
Therefore the coefficient of the difference between the estimates is $46 \%$, greater than $33.4 \%$, and so the extimate should not be released.

## Rule 5: Difference of Ratios

In this case, Rules 3 and 4 are combined. The cv's of the two ratios are first determined using Rule 3, and the cv of their difference is found using Rule 4.

## Confidence Limits

Although coefficients of variation are widely used, a more intuitively meaningful measure of sampling error is the confidence interval of an estimate. A confidence interval constitutes a statement on the level of confidence that the true value for the population lies within a specified range of values. For example a $95 \%$ confidence interval can be deseribed as follows:

If sampling of the population is repeated indefinitely, each sample leading to a new confidence interval for an estimate, then in $95 \%$ of the samples the interval will cover the true population value.

Using the standard error of an estimate, confidence intervals for estimates may be obtained under the assumption that under repeated sampling of the population, the various estimates obtained for a population characteristic are normally distributed about the true population value. Under this assumption, the chances are about 68 out of 100 that the difference between a sample estimate and the true population value would be less than one standard error, about 95 out of 100 that the difference would be less than two standard errors, and about 99 out of 100 that the differences would be less than three standard errors. These different degrees of confidence are referred to as the confidenee levels.

Confidence intervals for an estimate are generally expressed as two numbers, one below the estimate and one above the estimate, as $(-k,+k)$ where $k$ is determined depending upon the level of confidence desired and the satupling error of the estimate.

Confidence intervals for an estimate can be calculated directly from the Sampling Variability Tables by first determining from the appropriate table the coefficient of variation of the estimate, and then using the following formula to convert to a confidence interval Cl :

$$
\mathrm{Cl}_{\mathrm{x}}=\{\mathrm{X}-(\mathrm{t})(\mathrm{X})(\alpha), \mathrm{X}+(\mathrm{t})(\mathrm{X})(\alpha)\}
$$

where $\alpha$ is the determined coefficient of variation of the estimate $\mathbb{X}$
$t=1$ if a $68 \%$ confidence interval is desired
$t=1.6$ if a $90 \%$ confidence interval is desired
$t=2$ if a $95 \%$ confidence interval is desired
$t=3$ if a $99 \%$ confidence interval is desired

## Example 5(a):

An estimated 958.652 females aged 45 years and over have obtained a 'High school diploma' as the highest level of education. This estimate has an approximate cocfficient of variation of $2.3 \%$ (example 1). The $95 \%$ confidence interval for this essimate is

```
(958.652-(2)(958,652)(0).027), 958,652 - (2)(958,652)(0.02-7)
{958,652-51,767, 958.652+51,767}
{906,885, 1,010,419:
```

With $95 \%$ confidence it can be said that between 906.885 and $1,010,419$ of females aged 45 wears and over in Canada. have obtained a 'High school diploma' as the highest level of education.

## Example 5(b):

An estimated 16.4\% of females aged 45 years and over in Canada have obtained a 'High school diploma' as the highest level of education or 0.164 expressed as a proportion. From Example 2 this estimate has an approximate coefficient of variation of $2.6 \%$ A $95 \%$ confidence interval for this estimate (expressed as a proportion) is

$$
\begin{aligned}
C l & =\{0.164-(2)(0.164)(0.026),(1) .104+(2)(0.164)(0.1026) ; \\
& =\{0.155,0.173 ;
\end{aligned}
$$

With $95 \%$ confidence it can be said that between $15.5 \%$ and $17.3 \%$ of femates aged 45 vears and over in Canada have obtained a 'High school diploma' as the highest level of education.

Note: Release guidelines which apply to the estimate also apply to the confidence interval. For example, if the estimate is not releasable, then the confidence internal is not releasabte either:

## T-test

Standard crrors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The sample estimates can be numbers, averages, percentages, ratios, etc. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the characteristics are different when, in fact, they are identical.

Let $X_{1}$ and $X_{2}$ be sample estimates for 2 characteristics of interest. Le the sandard error of the difference $X_{\text {, }}$ - X2 be 0

$$
1 f_{1}=X_{-\cdots-----\quad X_{2}}^{\sigma} \text { is between }-2 \text { and } 2
$$

then no conclusion about the difference between the characteristics is justified at the 5\% level of significance. If however, this ratio is smaller than -2 or larger than +2 , the observed difference is significant at the $5 \%$ level (Note: at the $1 \%$ level, values of -3 and +3 should be used, ete.).

## Example 6:

1 user wishes to test at the $5 \%$ level of significance the hypothesis that at the Canada level there is no difference berween percentage estimates of males and females aged 50 to 64 who ohtained a High school diploma' as the highest level of education. From Example 4 the estimate of the standard deviation of the difference berween the estimates is 0.010 .

$$
\begin{aligned}
\text { Hence } & =\frac{0.14 l-0.163}{0.010} \\
& =2.2
\end{aligned}
$$

Since $=2.2$ is greater than 2, there is evidence to rejed the hypothesis at the $5 \%$ significance level.

INTERVIEWER:
Press $<$ F3> for demographic information.
Press $<$ F8 $>$ to view call history.
Press $\langle$ F11> to view case notes.
Press <Enter> to continue.

1. Continue

DIAL_PHONE INTERVIEWER: Dial the telephone number: ( ) $\qquad$ $-$

Have you made contact?

1. Yes, someone answers (Go to CN_Q03)
2. Answering machine (service or recorded message
3. No contact

CN_Q03 Telephone Number: ( ) $\qquad$ -

Hello, I'm ... from Statistics Canada.
Houschold respondent: Pre-filled
Telephone number: Pre-filled
Address: Pre-filled
INTERVIEWER: Introduce yourself using both your given and last names.
Press $<1>$ to continue.

TC_Q01 I would like to make sure I've dialed the right number. Is this (fill phone number)'?

1. Yes
2. No

SR_Q01 May I speak with 'pre-filled name?"?

1. Yes, speaking to respondent
2. Yes, respondent available now
3. No, respondent not available right now
4. No, respondent no longer a household member
5. Wrong number
6. Yes, which one?

IC_R01 I'm calling for a Statistics Canada survey.
INTERVIEWER: Press EEnter to continue

TRS_Q09 We need to confirm that we have found the correct \{Pre-filled respondent's name\}.

TRS_Q10 Could you tell me your date of birth?
INTERVIEWER: Enter the day
If necessary, ask: (What is the day?)

TRS_QIO Could you tell me your date of birth?
INTERVIEWER: Enter the month
If necessary, ask: (What is the month?)

1. January 7. July
2. February 8. August
3. March 9. September
4. April 10. October
5. May 11. November
6. Junc 12. December

TRS_QIO Could you tell me your date of birth?
INTERVIEWER: Enter a four digit year.
If necessary ask: (What is the year?)
(Roster_intro) You are the person we're looking for:
We're calling you for a survey on social support and aging in Canada. The purpose of the survey is to collect information on assistance provided to people aged 65 years and over as well as on retirement planning and experience.

Your answers will be kept strictly confidential and used only for statistical purposes.
This survey is a supplement to the Canadian Community Health Survey in which you participated last year. In order to keep this survey as short as possible, your answers will be added to those you gave when you were interviewed for the Canadian Community Health Survey.

While participation in this survey is voluntary, your cooperation is important to ensure that the information collected in this survey is as accurate and as comprehensive as possible.
(My supervisor is working with me today and may listed to the interview to evaluate the survey.)
What is the first name and age of each person living there? Include any person staying there who has no usual place of residence elsewhere. We'll start with you.

INTERVIEWER: Press $<1>$ to continue
(Ros_Name)Enter first household member's name. (The first name is sufficient).
First Name
MEM(1)
(Ros_Age) Enter member's age
INTERVIEWER: If the respondent is uncertain of a member's age, ask the respondent to provide an approximate age.
(Ros_sex) Enter member's sex.

1. Male
2. Female
(Ros_Name) Enter next household member's name. (The first name is sufficient).
Etc.
(ROS_member_list)
Is there anyone who USUALLY lives there that you may have left out such as a child, someone temporarily away (attending sehool, visiting, in hospital, traveling), another relative, a roomer or boarder, or an employee?

NAME AND AGE OF EACH HOUSEHOLD MEMBERS.
INTER VIEWER: Choose: To Continue / Add member / or Delete Member
Or press the < End> key to return to last answered question

1. Continue - No changes
2. Add a member
3. Delete a member

Format: I1
Weight variable: WGHT_PER
Note: $\quad$ This variable was derived using the children listed on the household composition matrix only. In cases of multigenerational households where the respondent lived with a spouse or partner as well as a child and a grandchild, FAMTYPE was set to 1 . In cases where the respondent had no children in the household and lived with only one parent, FAMTYPE was set to 5 . An intact family refers to a now-mamed or common-law couple where all children (listed in the household composition matrix) have both biological or adoplive parents in the household. A step family refers to a now-married or common-law couple in which at least one of the children (listed in the household composition matrix) is in a step relationship with one of the parents. The respondent might be a parent or a child aged 15 or older in the family.

Retirement does not necessarily mean stopping work permanently. Have you ever retired in any of the following circumstances?

- You became eligible for a pension or put in enough years for a pension.
- You received an early retirement package.
- You significantly reduced the amount of work you did for a business or farm you operated in order to retire.
- You were permanently laid off or lost a job and did not look for work or gave up looking for work in order to retire.
- You retired from a job or significantly reduced your work time because of your health
- You retired from a job or significantly reduced your work time because you could afford to live on your savings/investments.
- You retired from a job or significantly reduced your work time because you could afford to live on your spouse's/partner's investment or retirement income.
- You reduced your work time because of the health of your spouse or relative.

[^0]:    *With the tern 'qualitative estimales', we are referring to estimated population counts of persons possessing a characteristic measured by the survey. These estimated population counts are the estimated totals for an implicit indicator variable for the quality or characteristic of interest. For each person, this implicit variable is either 1 (when the person has the characteristic) or 0 (when the person does not have the characteristic). When the variable associated with the estimate can take on values other than 0 or 1 for each person, i.e. there is a count or quantity for each person, we refer to the estimate as "quantitative", e.g. average personal income or average size of household (number of members).
