

CLIMATE TRENDS AND VARIATIONS BULLETIN

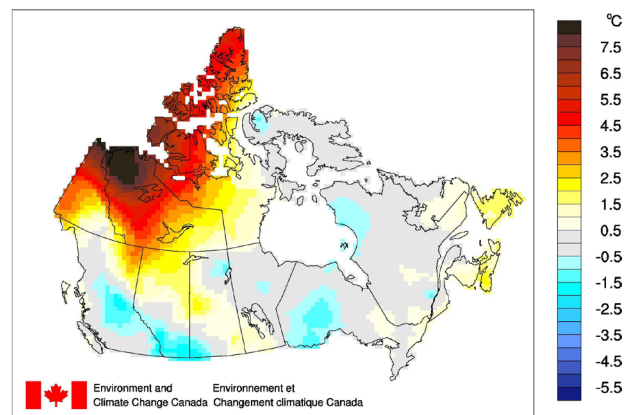

This bulletin summarizes recent climate data and presents it in a historical context. It first examines the national average temperature for the season and then highlights interesting regional temperature information.

Over the past decade, precipitation monitoring technology has evolved and Environment and Climate Change Canada and its partners implemented a transition from manual observations to using automatic precipitation gauges. Extensive data integration is required to link the current precipitation observations to the long term historical manual observations. The update and reporting of historical adjusted precipitation trends and variations will be on temporary hiatus pending the extensive data reconciliation, and resumed thereafter. ECCC remains committed to providing credible climate data to inform adaptation decision making, while ensuring the necessary data reconciliation occurs as monitoring technology evolves.

NATIONAL TEMPERATURE

The national average temperature for the winter (December-February) of 2017/2018 was 1.4°C above the baseline average (defined as the mean over the 1961–1990 reference period), based on preliminary data, which is the 25th warmest observed since nationwide recording began in 1948. The warmest winter occurred in 2009/2010, when the national average temperature was 4.1°C above the baseline average. The coldest winter occurred in 1971/1972, when the national average temperature was 3.6°C below the baseline average. The temperature departures map (following) shows that most of the Yukon, Northwest Territories, and western Nunavut as well as parts of British Columbia, Alberta, Saskatchewan, Manitoba, and Atlantic Canada experienced temperatures above the baseline average. Meanwhile, some areas in Nunavut, British Columbia, Alberta, Saskatchewan, Manitoba, Ontario, and Quebec experienced winter temperatures below the baseline average. Winter temperatures were near the baseline average in the remainder of the country.

TEMPERATURE DEPARTURES FROM THE 1961–1990 AVERAGE – WINTER 2017/2018

The time series graph (below) shows that averaged winter temperatures across the country have fluctuated from year to year over the 1948–2018 period. The linear trend indicates that winter temperatures averaged across the nation have warmed by 3.4°C over the past 71 years.

WINTER NATIONAL TEMPERATURE DEPARTURES AND LONG-TERM TREND, 1948–2018

REGIONAL TEMPERATURE

When examined on a regional basis, average winter temperatures for 2017/2018 were among the 10 warmest on record since 1948 for one of the eleven climate regions: the Mackenzie District region (9th warmest at 4°C above average). None of the eleven climate regions experienced an average winter temperature for 2017/2018 that ranked among the 10 coldest since 1948. All eleven climate regions exhibit positive trends for winter temperatures over the 71 years of record. The strongest regional trend (+5.7°C) is observed in the Yukon/North B.C. Mountains region, while the weakest trend (+0.7°C) is found in the Atlantic Canada region. A table listing the regional and national temperature departures and rankings from 1948 to 2018 and a table that summaries regional and national trends and extremes summaries are available on request to ec.bttvc-ctvb.ec@canada.ca.
