## **MANAGEMENT PERSPECTIVE**

<b>Title:</b>	An evaluation of the applicability of the <i>Tubifex tubifex</i> whole sediment reproductive bioassay for application in assessing effects from metal mining
<b>Authors:</b>	Danielle Milani, T.B. Reynoldson and P. Hoekstra
<b>NWRI Publication No:</b>	98-125
<b>Citation:</b>	NWRI report
<b>EC Priority/Issue:</b>	The Aquatic Effects Technology Evaluation Program (AETE) is evaluating methods and approaches to environmental monitoring, for potential application in the EEM for metal mining. As a part of this programme a series of sediment toxicity test are being examined for use in this national programme.
<b>Current status:</b>	Among the suite of tests being evaluated is the <i>Tubifex tubifex</i> 28-day reproduction test. This project is supported by the Canada Centre for Mineral and Energy Technology (CANMET), and involved the assessment of 63 sites from three mining locations. The functional responses of <i>T. tubifex</i> (survival and reproduction) were compared to acceptability criteria derived from reference sites sampled in the five Great Lakes over a 3 year period. Three categories of toxicity were developed based on results from 161-212 reference sediments. The 63 sites were classified according to the responses as 1) non toxic, 2) potential toxicity or 3) toxicity. These results showed little evidence of toxicity at these particular sites.
<b>Next steps:</b>	Data from this test will be compared to other bioassay results to examine their comparative performance and provide recommendations for the most appropriate suite of tests for the metal mining programme.

## **ABSTRACT**

The Aquatic Effects Technology Evaluation Program (AETE) is in the process of evaluating methods and approaches to environmental monitoring, for potential application in the EEM for metal mining. As a part of this programme a series of sediment toxicity tests are being examined for use in this national programme. Among the suite of tests being evaluated is the *Tubifex tubifex* 28-day adult reproduction test. Samples from 63 sites at three mining locations were examined. The functional responses of *T. tubifex* (survival and reproduction) were compared to acceptability criteria derived from reference sites sampled in the five Great Lakes over a 3 year period. Three categories of toxicity were developed based on results from 166-208 reference sediments. The 63 sites were classified according to the responses as 1) non toxic, 2) potentially toxic or 3) toxic. These results showed little evidence of toxicity at these particular sites.

## 1.0 INTRODUCTION

Toxicity test endpoints most appropriate for assessing ecological impacts are those associated with reproduction and life history (Reynoldson et al., 1991). The tubificid oligochaetes are one of the more widespread benthic groups, making them useful test organisms. The *Tubifex tubifex* 28-day reproduction test was developed at the National Water Research Institute (NWRI) as a component of sediment toxicity assessment (Reynoldson et al., 1991). The test is relatively simple and straightforward, and has been demonstrated to be repeatable and discriminatory (Reynoldson et al., 1991). Although *T. tubifex* does not exhibit discreet age classes, it has the following recognizable life history stages: breeding individuals, cocoons, newly hatched worms, and immature worms, which are used as endpoints in the test (Bonomi and DiCola, 1980; Reynoldson et al., 1991).

As part of the Aquatic Effects Technology Evaluation (AETE) program to evaluate methods and approaches to environmental monitoring, 63 samples from three mines have been assessed for sediment toxicity using the *Tubifex tubifex* 28-day reproduction test. These include the Myra Falls Mine, BC (21 sites); the Dome Mine, ON (21 sites); and the Mattabi Mine, ON (21 sites).

## 2.0 METHODS

### 2.1 Culture of Test Organism

Culturing methods for *T. tubifex* are outlined in detail in Reynoldson et al., (1991). Briefly, *T. tubifex* are cultured in 20 cm x 20 cm x 20 cm Plexiglas® aquaria at 23 °C ( $\pm 1^{\circ}\text{C}$ ). The culture medium is a natural marsh sediment from Long Point (Lake Erie) having a high organic carbon content and appropriate particle size for oligochaetes. This sediment has been used by NWRI, Burlington, ON, as a culture media for the past six years. Approximately 8 cm of sediment is added to a culture aquarium, then filled to the 20-cm mark with culture water (dechlorinated Lake Ontario tap water from the City of Burlington water supply). Once the sediment has settled, approximately 200 full cocoons

are added to the aquarium and the worms cultured to maturity (7-8 weeks). Sexually mature adults (gonads visible) are sieved out and sorted for testing purposes.

## **2.2 Sediment Sieving and Preparation**

Sediment samples are stored in the dark at 4°C until used in toxicity tests. Each sediment sample is completely homogenized, then sieved through a 250-µm sieve (Nytex®) to remove indigenous macrofauna (Reynoldson et al., 1994). A 4:1 ratio of culture water:sediment (2 L culture water:500 mL sediment) is used in the sieving process. Culture water is added gradually to the sediment to produce a slurry. This slurry is poured through the sieve, and the residue discarded. The sieved sediment is allowed to settle for a minimum of 24 hours, after which the water is decanted and used as the overlying water. Each 250-mL test chamber receives 100 mL of sieved sediment and 100 mL of overlying water. Food is added to each test chamber (80 mg of crushed Nutrafin®) and thoroughly mixed into the sediment-water slurry. The test chambers are then placed in a dark test incubator at 23°C ( $\pm 1^\circ\text{C}$ ) to allow the sediment to settle overnight. Once settled, the samples are aerated for 24 hours before the introduction of the animals. Five replicated beakers are prepared for each test site. In addition, a control sediment (Long Point) is included in each test to ensure that the test responses are within acceptable limits, thereby providing evidence of the health of the test organisms.

## **2.3 Toxicity Test Procedure**

On day 0 (start of test), water chemistry variables (pH, dissolved oxygen (mg/L), temperature (°C) and conductivity (µS/cm)) are measured and recorded for each replicate test chamber. Total ammonia concentration (mg/L) is also determined for each sample by taking a composite water sample from each replicate.

Sexually mature specimens of *T. tubifex* (identifiable gonads) are removed from the culture sediment by adding the sediment to a 500-µm sieve and gently immersing the

sieve into culture water. The worms are washed into petri dishes. These animals are transferred randomly to small plastic dishes containing culture water, until each dish contains four worms. The worms in the dish are added to each replicate beaker.

The test is conducted for 28 days; during this time, all test beakers are aerated, and water loss due to evaporation is supplemented with de-ionized water. Water levels in the test chambers are checked daily and airlines are checked twice daily to ensure proper levels are maintained throughout the test. On day 14 (mid-way point), water chemistry variables are again measured and recorded (pH, dissolved oxygen, temperature, and conductivity).

On day 28, water chemistry variables are measured for the final time, and total ammonia concentration is measured as before. The contents of each beaker are sequentially washed through 500- $\mu\text{m}$  and 250- $\mu\text{m}$  mesh sieves. The contents from the two sieves are washed separately into individual gridded plastic petri dishes for enumeration with a dissecting microscope. Endpoints measured include survival of the original adults, number of full cocoons, number of empty cocoons, number of small offspring (retained on 250- $\mu\text{m}$  mesh), and the number of large offspring (retained on the 500- $\mu\text{m}$  mesh). The results are expressed as four endpoints: mean % survival of adults, the mean number of cocoons per adult, the mean % cocoons hatched (empty cocoons versus total cocoons) and the mean number of offspring per adult. If adult survivorship is less than 100%, the number of cocoons per adult and the number of young per adult is achieved by taking the average of the number of surviving adults and the number of original adults (4). For example, if 3 out of 4 adult worms survived, the number of cocoons or young would be divided by 3.5 to achieve the number per adult.

## 2.4 QA/QC

The measured endpoints of *T. tubifex* in the laboratory control sediment (Long Point, Lake Erie) are plotted in warning charts (Figures 1, 2 & 3) (Environment Canada, 1990). The number that equals two times the standard deviation above and below the

mean, for each endpoint measured (the upper and lower 95% confidence limits) were plotted. These "warning limits" indicate the normal variability in test responses for *T. tubifex* in control sediment. Each AETE test was compared against these established warning limits. If the test data fell within the limits, they were included in the data set.

Coefficients of Variation (CV) are also determined for the three mine locations for each of the four endpoints to evaluate the precision of the endpoints. The overall mean CV and the range are included at the bottom of each of the 12-endpoint tables (Tables 2 to 13). The CV is used to determine the precision of the test, and a CV of  $\leq 20\%$  is generally recommended for laboratory replication.

### 3.0 RESULTS

The toxicity test results are presented for mean adult survivorship (Tables 2, 3 & 4); mean number of cocoons/adult (Tables 5, 6 & 7); mean number of young/adult (Tables 7, 8 & 9); and mean % cocoons hatched (Tables 11, 12 & 13). Total ammonia concentrations, measured on day 0 and day 28 are presented in Tables 14, 15 & 16. To assess the response of the test endpoints these data have been compared to acceptability criteria derived from reference sites sampled in the Great Lakes over a three year period (Reynoldson et al., 1995; Reynoldson et al., 1997). Three categories of toxicity were developed for four species from sediments in the Great Lakes based on the results from 161-212 reference sediments. The categories are: (1) non-toxic; (2) potential toxicity; and (3) toxicity. The delineations for each of the categories for *T. tubifex* in whole sediment toxicity tests are presented in Table 1. An upper limit is provided in the non-toxic category for reproduction based on twice the standard deviation of the mean. Toxicological effects on sublethal responses are usually considered negative, i.e., growth or reproduction is reduced in comparison to a control. However, in areas of eutrophication or high nutrient impact, sublethality may manifest itself as an increase in biomass or production of young. This effect could have a negative impact on the structure and function of benthic invertebrate communities in aquatic ecosystems.

Therefore, an upper limit for reproduction by *T. tubifex* has been set for the non-toxic category.

**Table 1: Limits derived from Great Lakes reference sites for determining toxicity of *T. tubifex* test endpoints**

<b>Species</b>	<b>Non toxic (Class 1)</b>	<b>Potentially toxic (Class 2)</b>	<b>Toxic (Class 3)</b>
<i>T. Tubifex</i>			
survival (%)	>88	84 - 87.9	<84
hatch (%)	40 - 78	30.8 - 39.9	<30.8
cocoon/ad. (no.)	7.2 - 12.3	5.9 - 7.1	<5.9
young/ad. (no.)	12.0 - 45.6	3.6 - 11.9	<3.6

The use of two and three times the standard deviation about the mean for each endpoint has been chosen to separate these response categories because it was established to be a more conservative delineation of toxicity than the *Minimum Detectable Differences* (MDD's) determined from the Great Lakes data (Reynoldson et al., 1997).

#### **Adult Survivorship: (Tables 2, 3 & 4)**

Adult survival was high in all sites tested (90 - 100%). CV's are low ranging from 0 – 15.2%. All sites are classified as non-toxic.

#### **Cocoons/adult: (Tables 5, 6, & 7)**

The number of cocoons produced per adult was sufficient to classify all sites as non-toxic, with the exception of Mattabi Mine sites MMSR2-2 (5.4 cocoons/adult) and MMSR2-3 (7.0 cocoons/adult). These sites are classified as toxic and potentially toxic respectively. Coefficients of variation were ≤ 18.2 %.

***Percent Cocoons Hatched:*** (Tables 8, 9, & 10)

The percentage of cocoons produced that hatched was sufficient in all sites tested (41.9 - 71.8%), thereby classifying all sites as non-toxic. Coefficients of variation were ≤ 22.6%.

***Young/adult:*** (Tables 11, 12 & 13)

The number of young produced per adult was sufficient in all sites to be classified as non-toxic, with the exception of Myra Falls site MN7-S (10.5 young/adult), classifying it as potentially toxic. The range in coefficient of variation was higher for the number of young/adult produced (3.2 – 55.9); however, overall means were ≤ 18.8%.

***Total Ammonia Levels:*** (Tables 14, 15 & 16)

Elevated concentrations of total ammonia were recorded on day 0 in Mattabi Mine sites MMSR1-2 (6 mg/L), MMS5-3 (5.5 mg/L) and Dome Mine site D3-1 (5.5 mg/L). By the end of the test, (day 28), these levels were reduced considerably.

#### **4.0 CONCLUSION**

These results showed little evidence of toxicity. None of the samples from Dome mines showed evidence of sediment toxicity, and one sample from Myra Falls indicated potential toxicity (Table 11). Only two of 21 sites (Table 7) from the Mattabi Mine were toxic based on cocoon production, MMSR2 (toxic) and MMSR3 (potentially toxic). At both these sites young production was also reduced (Table 13), but was within the criteria established. However, young production is less sensitive than cocoon production because of the greater variability observed in young per individual. It is not possible to interpret these results further in the absence of supporting physical or chemical characterisation of the samples. The elevated total ammonia concentrations observed in Mattabi Mine sites MMSR1-2 (6 mg/L), MMS5-3 (5.5 mg/L) and Dome Mine site D3-1

(5.5 mg/L) did not appear to contribute to toxicity. These sites were classified as non-toxic for all endpoints.

For all test endpoints, the mean CV's were all below the recommended 20%. The CV ranges were greatest for the number of young produced per adult (3.22 - 55.88). This is to be expected, as this endpoint in general tends to be the most variable. For each data set (AETE 1 to 9), the test responses in the laboratory control sediment (Long Point) are within the acceptable limits, thereby accepting all test data.
