ABSTRACT

Water quality (physical, chemical and bacterial) and benthic invertebrate data were obtained from Lake Laberge during 1977, 1978 and 1980 surveys. The influence of the Yukon River and the human settlements near the lake are discussed.

The results have indicated that the water quality of the upper end of Lake Laberge has been affected by the City of Whitehorse sewage lagoon and to a lesser extent by the settlement near Deep Creek, suggested by the level of coliform bacteria.

RESUME

Des données physico-chimiques et bactériologiques de l'eau du lac Laberge de même que des résultats de la faune benthique ont été obtenues durant les études 1977, 1978 et 1980. L'influence du fleuve Yukon et des habitations humaines près du lac y est discutée.

Les résultats ont indiqués que la qualité de l'eau du lac Laberge a été affectée par le système de traitement des eaux usées de la ville de Whitehorse et par les résidents près de Deep Creek dans une moindre mesure, suggéré par le niveau de bactéries coliformes.

1 INTRODUCTION

During the summers of 1977, 1978 and 1980 the Environmental Protection Service (EPS), Yukon Branch undertook the collection of water quality information from Lake Laberge. The purpose was to provide data on relevant parameters before and after Whitehorse sewage lagoon installation and to determine the contribution of cottages along the lakeshore to bacterial levels in the water.

The purpose of this report is to compile the information gathered and provide a summary of conditions for the various parameters in relation to water quality standards. The information recorded will be of value in assessing the effectiveness of future upgraded sewage treatment facilities in Whitehorse and the influence on receiving water quality.

During the period of information collection, there were changes in laboratory procedures, some new sampling stations were added and some sampling stations deleted which has made comparison of data difficult.

2 STUDY AREA

Lake Laberge is located at 61° 11' N latitude and 135° 12' W longitude in the central southern part of the Yukon Territory (Figure 1). The lake is a part of the Yukon River hydrographic system and is situated about 30 km downstream from the city of Whitehorse sewage treatment plant discharge. The lake is 48 km long. The upper 14 km was sampled.

The sampling stations are arranged in transects across the lake at varying distances downstream from the confluence of the Yukon River with the lake. This allows data to be collected and related to human activity upstream on the Yukon River at Whitehorse or to human settlement at Deep Creek and Jackfish Bay on Lake Laberge. Figure 2 shows the location of these sampling stations and the periods which they were sampled. A bathymetric map of the study area is presented on Figure 3.

 STUDY AREA

3 METHODS

3.1 Water Quality

Temperature, conductivity and pH were measured in the field at each site. Samples were collected for analysis of nutrients and metals. These analyses were performed at the Environmental Protection Service regional laboratory in West Vancouver. Appendix I, Table 1 describes standard sampling, preservation and analytical procedures used for all parameters. Appendix I Table 2 shows the data obtained according to the sampling period and the parameters.

3.2 Bacteria

Bacteria samples were collected for total coliform counts in 1977 through 1980 and fecal coliform counts in 1978 through to 1980. These samples were analysed at the Whitehorse laboratory of the Environmental Protection Service using the membrane filter technique. Total coliform densities were analysed on Difco M-Endo Agar after incubation of 18 to 24 hours at $35^{\circ}\text{ C} \pm 0.5^{\circ}\text{ C}$. Fecal coliform densities were analysed on Difco M-FcAgar after incubation at $44.5^{\circ}\text{ C} \pm 0.2^{\circ}\text{ C}$ for 18 to 24 hours. No preincubation period at room temperature was used for fecal coliforms.

3.3 Bottom Fauna

The bottom fauna sampling schedule is given in Table 1 Appendix III. Bottom fauna collection, preservation and identification methods are given in Appendix I Table 3. The classification of the bottom fauna follows Cumming and Merritt (1978) for the insects and Pennak (1978) for all the other taxonomic groups. To evaluate the diversity of the community at each sampling station, the Shannon index for diversity and the evenness formulae from Pielou (1975) were used.

a) Shannon diversity index

$$H' = - \sum (P_j \log P_j)$$

$$P_j = n_j/N$$

n_j - Total number of individuals in the
ith species

N = The total number of individuals
sampled

b) Evenness

$$J' = \frac{-\sum (P_i \log P_i)}{\log S}$$

where S = total number of species sampled

For the purpose of this report, S = genera instead of species and therefore n_i = the total number of individuals in the i^{th} genera.

4

RESULTS

4.1 Water Quality

The water quality data obtained in this study are presented in Appendix II. Each survey is presented on a separate table (Table 1-9).

4.1.1 Ammonia, Nitrite, Nitrate. The nitrogen compound ammonia is abundant only in deoxygenated water and reducing conditions. It will occur then generally in polluted areas and the hypolimnion of eutrophic lakes. The nitrites are generally absent from the surface water unless it is polluted. The nitrates are the usual form of assimilation of nitrogen by plants and are provided by aerobic decomposition and by the blue-green algae and bacteria fixation. These compounds are distributed through the lake by the thermal turn-over.

The maximum recommended levels of nitrogen-compounds for drinking water is 0.5 mg/l for ammonia, 10 mg/l for nitrates and 1 mg/l for nitrites (Working Group, 1977, EPA, 1973). In Lake Laberge there were no values for the above nitrogen compounds which were above the recommended guideline and usually they were near or below the detection limit. The nitrogen compound range from <0.005 mg/l to 0.032 mg/l for ammonia, <0.01 mg/l to 0.038 mg/l for nitrates and always <0.005 mg/l for nitrites.

4.1.2 Phosphate. Phosphate is usually a limiting factor for the growth of algae (Wetzel, 1975). The phosphate comes from various sources, such as degradation of rocks, and organic matter, from pollution by detergents, fertilizers or organic pollution. Phosphorus is retained in the sediments by the oxygenated water which precipitates the element (Wetzel, 1975). The level recommended (0.020 mg/l) is based on limnological concerns to prevent eutrophication of a lake rather than health hazards (Ontario, 1978). Only one station in July 8-11, 1980, shows a level of 0.182 which was above the recommended

level. That station is #20 at 25 m depth which might be caused by the bottom decomposition in spite of the DO level which is 10.16 mg/l, and 90 % saturation. The sample might be taken close to the sediment water interface, the suspended solid (NFR) at that station was high, perhaps due to disturbance by the sampler.

4.1.3 Total Organic Carbon. Total organic carbon (TOC) is a technique for estimating the organic content in the water. A high level of TOC might indicate organic pollution. The Ontario Ministry of Environment (1978) has recommended a maximum level of 5.0 mg/l for the public water supply. In Lake Laberge, there were no levels that exceeded this limit. The range of the values are <1.0 mg/l to 5.0 mg/l.

4.1.4 Colour and Turbidity. Colour is the resulting effect of dissolved compounds on the absorption of light. Compounds such as hydroxy carboxylic acid, humic acids, iron, and manganese are the most important contributors. The recommended maximum of 75 platinum-cobalt colour units is far greater than what is found in Lake Laberge during the survey in 1980.

Turbidity is the measurement of transparency of the water and is affected by plankton and sediment particles of different sizes. It reflects the amount of suspended solids in the water which can reduce the amount of light available for the biological processes. For Lake Laberge, the turbidity was low, \leq 5 FTU which indicates a clear water.

4.1.5 Chloride, Sulfate. The data obtained in 1980 for chlorides show concentrations mostly below the detection limit of 0.5 mg/l. The level for drinking water should not exceed 250 mg/l. According to Wetzel 1975, the mean concentration of chloride in natural fresh water is 8.3 mg/l which is above the concentration found in Lake Laberge.

The recommended level of 250 mg/l (EPA, 1973) is not exceeded in Lake Laberge which has values between 4 and 10 mg/l with some peaks of 39.6 mg/l and 46.5 mg/l in Deep Creek.

4.1.6 pH. In lakes with good buffering capacity, the pH of natural water varies between 7-8. The pH of Lake Laberge varied between 7.5 and 8.2 through the study, which is fairly constant, and very acceptable.

4.1.7 Conductivity, Alkalinity and Hardness. The conductivity varies from 56 to 85 umhos/cm in most stations except for stations 1,2 and 3 which show values ranging from 100-370 umhos/cm. This is attributed to the minerals carried by Deep Creek, which also shows a hardness of 70 to 230 mg/l as CaCO₃ compared to the range of the stations on the lake from 36-64 mg/l as CaCO₃. The alkalinity varies from 35 to 50 mg/l as CaCO₃. The alkalinity shows a good buffering capacity which explains why the pH is maintained in a fairly narrow range. There are no recommended levels for conductivity and alkalinity for drinking water (EPA, 1973).

4.1.8 Non-Filterable Residue - NFR. The NFR is the equivalent of the more familiar suspended solids. The results of the study show a very low level of suspended solids, always near or below the detection limit. There is only one station at which the level was higher (Station 20-25m, 139 mg/l). According to the level of phosphate found at that station, it is suggested that the sample was close to the bottom surface where a lot of solids remain in suspension due to the slow water movements or that they had been disturbed during sampling activity. There is no correlation with the number of coliforms at that area.

4.1.9 Filterable Residue - FR. This parameter is the equivalent of the total dissolved solids. It shows the degree of mineralization of the water. The range of values for the filterable residue is 46-75 mg/l, with a peak for stations 1,2 and 3, (88-305 mg/l) which correlates with the hardness, alkalinity and conductivity in the water. It is proposed by EPA (1973) that the filterable residue not exceed 500 mg/l, but it was also observed that no obvious effect results from an excess of dissolved solids.

4.1.10 Oxygen. The percentage saturation of oxygen in Lake Laberge ranges from 85-120% which is satisfactory. A good level of oxygen is an indicator that there is no excessive quantity of oxygen demanding material, helps to transform ammonia to nitrate, to precipitate the excess phosphates, iron, and manganese.

4.1.11 Temperature. There was no thermal stratification found in Lake Laberge during the three year survey. This might be caused by the high surface exposed to the prevailing wind that blows south to north, which is the same orientation of the lake and the short retention time of the water in the lake (summer average, 0.52 years, C.H. Pharo, personal communication). There was some increase in temperature near the tributaries of the lake (Yukon River, Deep Creek) as well as shallow areas such as Jackfish Bay.

4.1.12 Metals. All metals except aluminum, manganese and iron were below the detection limit or under the maximum recommended level (EPA, 1973) for any station at all depths and sampling dates. In the case of aluminum, the level should not exceed 0.1 mg/l of ionized or potentially ionizable aluminum (Ontario 1978) because at high levels it is deleterious to growth and survival of fish. The level has been exceeded several times (Table I) but it should be mentioned that with a pH between 7.5 and 8.2 it is rather probable that the aluminum would be unionized (Kelso, personal communication). It is clear, by the distribution of elevated levels, that the Yukon River is the source of the aluminum. The Yukon River study by Bethell (1981) shows that stations near the lagoon outfall and at the junction of the Takhini and Yukon rivers exceed the recommended levels by up to ten times.

Manganese levels exceeded the levels recommended for drinking water (0.05 mg/l set for alsthetic reasons) at Stations 6 and 13 on July 10-12, 1978; all stations except Station 2 on August 22-25, 1978; and Stations 6,7 and 8 on July 8-11, 1980. None of these levels exceeded the recommended level of (1.0 mg/l) for aquatic life.

										27	0 0.213
										28	0 0.262

= Station Number

D = Depth (m)

Al = Concentration of Aluminum (mg/l)

Iron does not exceed the level recommended for aquatic life (1.0 mg/l) although the recommended level for drinking water of 0.3 mg/l, set for aesthetic and taste reasons, is exceeded at Stations 24 and 28, July 10-12, 1978; Stations 23-28, July 8-11, 1980.

4.2 Bacteria

The coliform bacteria are used as indicators of sewage pollution. Escherichia coli is a normal inhabitant of the human digestive system. Their presence suggests potential for contamination by enteric bacteria such as Salmonella sp. and Shigella sp. which are agents of intestinal disease such as dysentery and typhoid fever. The total coliform count is an indicator of sanitary conditions but is not a proper measurement of fecal contamination because coliform bacteria are wide spread in the environment and not specific to fecal material. Some reports indicate that a sharp increase of the frequency of Salmonella sp. detection occurs when fecal coliforms are above 200/100 ml (EPA, 1972). The criteria recommended by the Working Group on Water Quality Objectives (1977) for the Yukon is 100 total coliforms per 100 ml (100/100 ml) as acceptable limits and 1000/100 ml as a maximum limit before treatment. The acceptable limit for fecal coliforms is 10/100 ml and a maximum of 100/100 ml for public water supply before treatment. Some of the data shows results exceeding the maximum limits for total coliforms in August 22-25, 1978, July 8-11, 1980 and August 5-8, 1980 (See Table II and III for more details). On August 29, 1977, the level of total coliform is below the acceptable limit while all the other values are over 100 total coliforms/100 ml. The maximum limits of 100 fecal coliforms/100 ml has been reached at some stations at each sampling period. Every period of time where that parameter has been considered shows values exceeding the acceptable limit for some stations. Figures 3-8 indicate the abundance and distribution of the total coliforms and Figures 9-14 show the fecal coliform distribution and abundance. Those distributions are not necessarily surface

concentrations but the value of the highest concentration at that particular station. Jackfish Bay is the only area near a settlement which did not indicate any fecal coliform pollution.

4.3 Bottom Fauna

During the survey, 3,748 organisms were collected and identified to the species level where possible; or the genus or family level if species identification was not possible. It is the total count of individuals collected during the survey. This resulted in the identification of 97 different taxonomic groups as shown in Appendix III Table 2. The most abundant family is the Chironomidae (1,494 individuals) followed by the Tubificidae (821 individuals), the Valvatidae (373 individuals), the Sphaeriidae (163 individuals), and the Lymnaeidae (76 individuals). The thirty remaining families each had less than 40 individuals represented in the total count of all the samples. Table 4 provides a categorization of the genera represented in relation to the number of individuals sampled and the percent frequency of their occurrence in all the samples.

TABLE 4 NUMBER AND PERCENT FREQUENCY OF THE MOST REPRESENTED GENERA IN THE STUDY

GENERA (family)	NO. OF INDIVIDUALS in all samples	FREQUENCY (%)
<u>Limnodrilus</u> (Tubificidae)	410	48.39
<u>Rhyacochillus</u> (Tubificidae)	381	45.16
<u>Valvata</u> (Valvatidae)	373	70.99
<u>Proctadius</u> (Chironomidae)	314	74.19
<u>Eukiefferiella</u> (Chironomidae)	233	43.55
<u>Psectrocladius</u> (Chironomidae)	253	27.42
<u>Microspectra</u> (Chironomidae)	205	33.87
<u>Pisidium</u> (Sphaeriidae)	163	48.39
<u>Tribelos</u> (Chironomidae)	127	33.87
<u>Chironomus</u> (Chironomidae)	88	20.97
<u>Stictochironomus</u> (Chironomidae)	82	11.29
<u>Lymnae</u> (Lymnaeidae)	76	24.19
TOTAL OF SAMPLES TAKEN = 62		

The two most abundant genera belong to the order Annelida. The next most abundant genus belongs to the order Mollusca followed by many genera of the family Chironomidae of the order Diptera. The most frequent genus is Procladius of the Diptera which is a predator but may function as a collector-gatherer (Merritt 1978).

The other Chironomids are typically collector-gatherers which live in the lentic profundal zone with some on the lentic littoral zone.

The density of individuals varies, but generally the greatest number of organisms occur in the littoral zone while in the deep profundal zone the populations are less dense.

The diversity index shows low values, with a very wide range (0.0-.96). The samples taken show a low number of individuals which may be caused by a poor benthic community or by poor sampling techniques that is, the jaws not properly closed. The variations of values can also be greatly influenced by seasonal changes as well as the low biotic capacity of the substrate.

APPENDIX I TABLE 3 BOTTOM FAUNA COLLECTION, PRESERVATION AND IDENTIFICATION METHODS

FIELD COLLECTION, SAMPLING PROCEDURES AND PRESERVATION	LABORATORY PROCEDURES	IDENTIFICATION AND ENUMERATION
Eckman dredge: The samples were taken using an Eckman dredge of 15 cm x 15 cm x 23 cm in size. The sample area 225 cm ² (.25 ft ²).	Bottom fauna was removed from other material and placed in a labelled vial containing 70% methanol.	Bottom fauna was sent to Dr. Charles Low, Consulting Invertebrate Biologist, at Nanaimo, British Columbia, for identification to genus, species if possible, and enumeration.

- The conductivity meter ceased functioning and measurements for conductivity and temperature could no longer be taken.

NOTE: Samples 22 through 28 were delayed in transit and analyzed 4 1/2 months after collection so many of the results could be unreliable.

APPENDIX III TABLE 2 TAXONOMIC LIST OF THE BOTTOM FAUNA
COLLECTED IN LAKE LABERGE

		1977	1978
1.	Phylum: <i>Coelenterata</i> Order: <i>Hydroida</i> Family: <i>Hydridae</i> <u>1.</u> <i>Hydra</i> sp.		x
2.	Phylum: <i>Nematoda</i>	x	x
3.	Phylum: <i>Annelida</i> Class: <i>Oligochaeta</i> Order: <i>Haplotaxida</i> Family: <i>Enchytraeidae</i> Family: <i>Naïdidae</i>	x	x
4.	<i>Naïs</i> sp.	x	
5.	<i>Naïs behningi</i>	x	
6.	<i>Naïs (communis?)</i> sp.		x
7.	<i>Stylaria lacustris</i>	x	
8.	Family: <i>Tubificidae</i> (juveniles) <u>8.</u> <i>Potamothrix</i> sp?		x
9.	<i>Limnodrilus</i> sp?		x
10.	<i>Rhyacodrilus</i> sp?		x
11.	<i>Limnodrilus</i> sp.	x	x
12.	<i>Rhyacodrilus</i> sp.	x	x
13.	Order: <i>Lumbriculida</i> Family:		
14.	<u>13.</u> <i>Lumbriculus variegatus</i> <u>14.</u> <i>Stylodrilus</i> sp.	x	
15.	Class: <i>Hirudinea</i> Order: <i>Glossiphonidae</i> Family: <i>Rhynchobdelliida</i> <u>16.</u> <i>Batrachobdella</i> sp.	x	
16.		x	

APPENDIX III TABLE 2 TAXONOMIC LIST OF THE BOTTOM FAUNA
COLLECTED IN LAKE LABERGE (continued)

		1977	1978
	Phylum:	Arthropoda	
	Class:	Crustacea	
	Order:	Cladocera	
	Family:	Chydoridae
