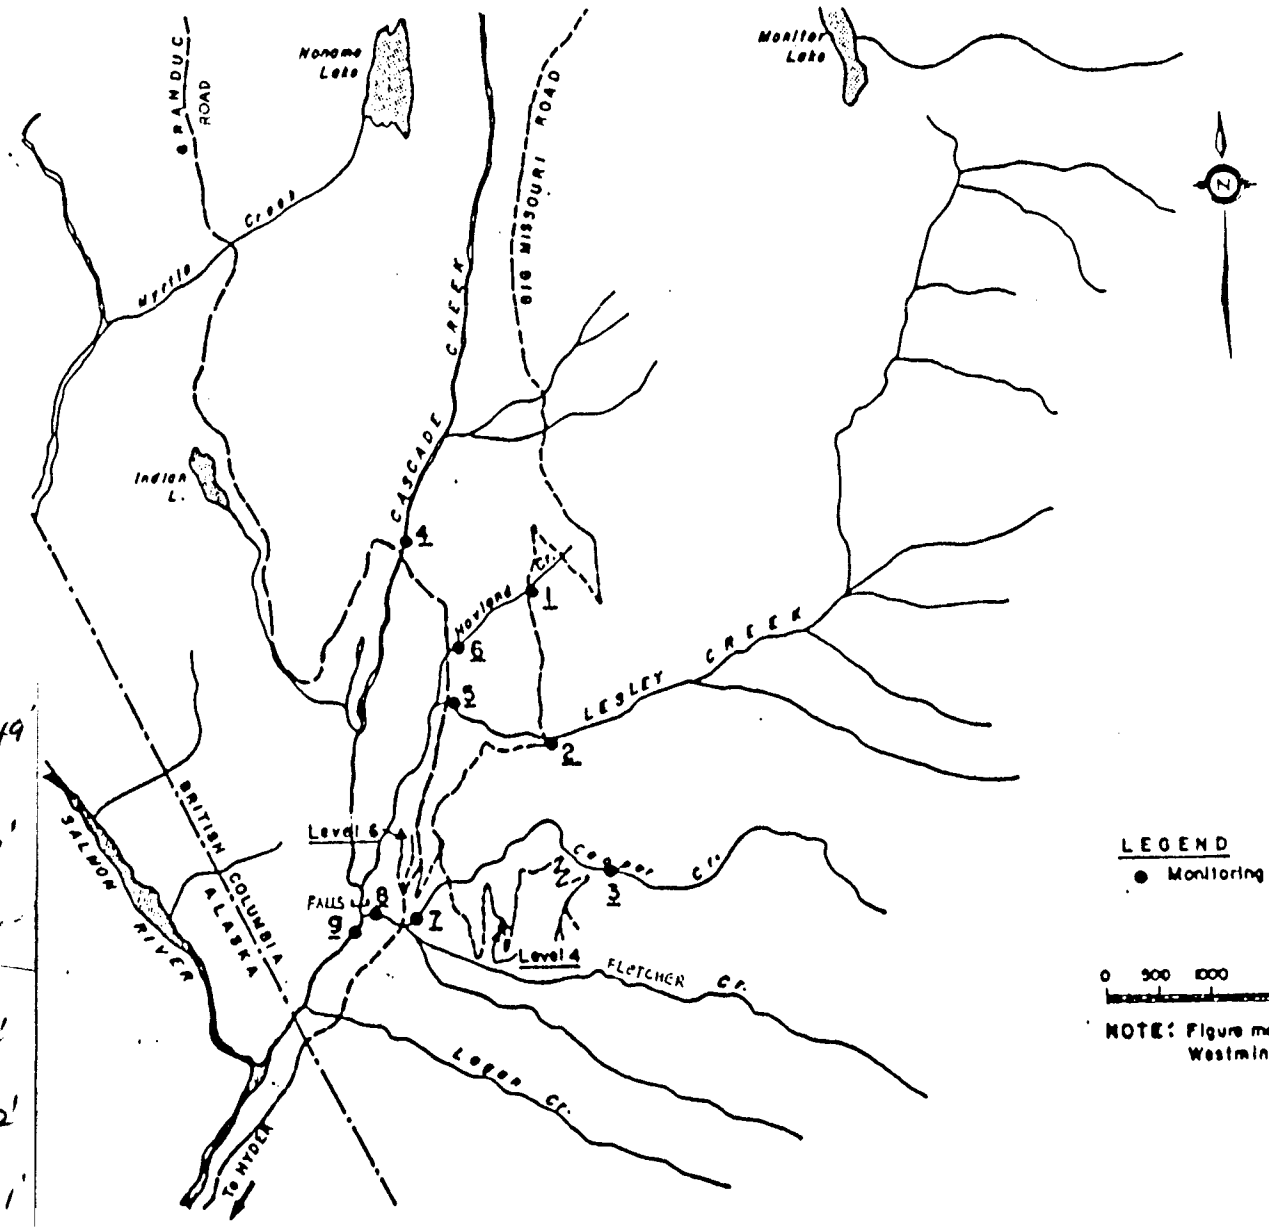
LIST OF TABLES

1.0 Introduction

The Premier Gold project is located in the Salmon River drainage system. The mine is located on the east side of the Cascade Creek valley, about 1 km upstream of the border. The Premier Gold mine site is drained by Cooper Creek to the north and west while the drainage at the south part of the mine is by Fletcher Creek. Both creeks join above the Granduc road to form Fletcher Creek, which flows into Cascade Creek immediately below the falls (Figure 1). The falls on Cascade Creek are an impassable barrier to salmon migration. Cascade Creek joins the Salmon River about 1.5 km downstream (Figure 2). Salmon River supports chum, pink, and coho salmon, and the occasionnal sockeye salmon.

The company is developing an open pit mine. A cyanide leach is used to extract gold and silver. The tailings pond is located in the Cascade Creek valley. The upper part of the Cascade Creek has been diverted to the Lesley Creek channel. The tailings will be discharged using the subaerial technique and the supernatant discharged to Cascade Creek above the falls.



Cascade Creek	55°22'	129° 49'
Cascade Falls	57°28'	130° 16'
Fletcher Cr	56°06'	130° 00'
Cooper Cr	56°03'	130° 02'
Lesley Cr	56°03'	130° 02'
Howland Cr.	56°04'	130° 01'

STATION	LOCATION
2	Lesley Creek upstream of the mill
3	Cooper Creek upstream of the open pit
4	Cascade Creek upstream of the tailings pond
5	Lesley Creek downstream of the mill
7	Cooper Creek downstream of the open pit
9	Cascade Creek downstream of the tailings pond
10	Salmon River at mile 14
Level #4	Mine portal
Level #6	Mine portal

3.0 MATERIAL AND METHODS

The mine site was visited on August 9, 1988. No flow measurements were taken at the sampling stations. Water chemistry samples were collected at eight stations. The same numbering of the stations was used as in the previous baseline water quality report (Godin 1988). Sediment samples were collected at the same eight sites and at Station 10 on the Salmon River. The following chemical parameters were analysed: alkalinity, pH, conductivity, total residue, non filterable residue, and sulphate. These samples were kept cool with ice until analysed. Dissolved metals were filtered the same day through a 0.45 micron cellulose nitrate membrane filter. Total and dissolved metals were preserved with nitric acid (0.5 ml/100 ml of sample). All samples were collected with clean polyethelene bottles. The bottles for metal samples were previously acid washed. The hardness was determined from the dissolved metal sample.

Inductively Coupled Argon Plasma (ICP) was used for the total and dissolved metal analysis and gave a reading of twenty-six metals. For cadmium, copper, and lead the samples were re-analysed with the graphite furnace when the values were below two times the detection limit on the ICAP procedure. For analytical methods details refer to the Environment Canada Pacific Region Environmental Laboratory Manual (Anon., 1979).

Sediment samples were collected from the streambed below the water level, with a clean acrylic corer. Four replicates were taken at each site. The samples were transferred into kraft bags and kept cool until analysed. The samples were air dryed, sieved to <150 um, digested with aqua regia, and analysed for heavy metals using ICP. A portion of the sediments were also ignited at 550°C in a muffle furnace. The loss of weight was reported as volatile residue and the remaining residue was reported as fixed residue.

4.0 RESULTS

The water metal results can be found in Table 1, while the other water quality results are found in Table 2. The sediment data are reported in Table 3.

Orange staining on the streambed of Cooper Creek at Station 7 observed in the 1987 inspection was not present in 1988. This may be related to increase in flow during freshet. The higher flows may have washed away the accumulated precipitate. Stations 7 and 9 on Cooper Creek and Cascade Creek respectively, indicated increases in non-filterable residue, both in comparison to the other stations sampled in 1988 and Stations 7 and 9 from survey 1987. Several metals were elevated at the downstream Station 9, compared to 1987's survey, such as: Ba, Fe, Mn, Pb, and Zn. Cadmium was elevated at most stations compared to last year. Sulphate was only elevated at Station 7 downstream of the level #4 mine portal.

Water quality at the two mine portals showed higher total metal concentrations for Al, Cd, Cu, Fe, Mn, Pb, Zn, and higher dissolved metals for Cd, and Zn compared to last year's survey. The non-filterable residues were higher at Level #6 while the sulphate concentration was higher at Level #4.

Sediment analysis generally showed no statistical differences between Lesley Creek Station 2 and 5 except for arsenic where elevated concentrations were found at Station 2 the upstream site. For all statistical differences, the reader is referred to Figures 3 to 5 for multiple comparison plots and Table 4 for statistical station separations. Metal concentrations at Station 7, the downstream site on Cooper Creek, were significantly higher than Station 3, the upstream site, for Cu, Hg, Pb, and Zn. No significant differences were found between Station 4 and 9, on Cascade Creek, for trace metals. High variability in cadmium content measurements prevent an evaluation of differences even though high levels were found at Station 7.

	2	bc		7	abc		9	bc
	7	bc		4	bc		7	bc
	4	cd		3	c		5	bc
	9	d		9	d		10	c
Calcium	5	a	Mercury	10	a	SVR	10	a
	4	a		5	a		5	ab
	9	ab		2	a		7	ab
	3	abc		3	a		9	ab
	7	bc		9	b		4	ab
	2	c		4	b		2	b
	10	c		7	c		3	c
Chromium	7	a	Lead	3	a			
	5	ab		5	a			
	3	abc		10	a			
	9	abc		2	a			
	2	bc		4	ab			
	10	c		7	b			
	4	d		9	b			

Note : The stations are ranked by the lowest mean. The separation is determined by the overlapping confidence intevals.

Sediment comparisons from last year's survey showed that arsenic sediment content was generally higher in 1988 than in 1987 while cadmium and mercury were consistently lower. The copper, lead and zinc content in the sediments, in 1988, was higher at Station 4 and 9, (respectively Cascade Creek upstream and downstream stations), but were not reduced at Station 7.

Sediments collected at level #4 and #6 showed contamination for various heavy metals. The following values (µg/g) are an average of metal content at level #4 and #6 respectively: As (125 and 93); Cd (192 and 68); Cu (2547 and 703); Hg (4.78 and 1.07); Pb (6948 and 2355); Zn (19275 and 9220). These highly elevated metal values are a relection to the contaminated water quality from the two adits.
