DOWNSVIEW 1972

ATMOSPHERIC ENVIRONMENT SERVICE  
DEPARTMENT OF THE ENVIRONMENT  
CANADA

B. J. Yorke and G. R. Kendall

Normal values of daily bright sunshine for each month and for years, based on the period 1941 to 1970, are listed in this circular. The data represent the values given in Climatic Normals Volume 2, which were based on the period 1941 to 1969, of the most up-to-date Canadian bright sunshine data.

The observations presented in this circular were made with the Campbell-Stokes sunshine recorder used in the U.S. It is a modified instrument which records the length of time total radiation exceeds a certain threshold value. As the total radiation includes a contribution from the sky as well as that from the sun the measurements are not strictly comparable with those from the Campbell-Stokes. The difference varies but along the Canada-United States border average monthly totals from the Mavis instrument are a fraction of an hour less in November, December and January, but are about an hour greater during the summer season from April to September.

There is no simple relationship between the duration of bright sunshine and the amount of radiation occurring at any station because of varying solar elevation angle and other factors.

BY

**B.J. YORKE and G.R. KENDALL**

**CLI-6-72**

1. Normals computed from a period of record of 30 years from 1941 to 1970.

2. Normals computed from 10 to 29 years of records within the period 1941 to 1970.

Averages were computed from less than 10 years of record within the period 1941 to 1970.

The Maps - The map showing total hours of sunshine in the summer months is indicative of conditions during the part of the year when outdoor activity is greatest. The maximum values occur in the southern prairies where totals for the five months exceed 1400 hours, an average of just over nine hours a day. Totals almost as high are found as far north as the mouth of the Mackenzie. In higher latitudes the possible duration of sunshine is greater than in the south but the cloud associated with open water prevents sunshine totals from getting as large as those on parts of the mainland. The lowest totals are found over Hudson Bay and adjacent parts of northern Quebec. On the island of Newfoundland available stations show totals less than 900 hours but there would probably have been higher values at inland sites had been made.

**DOWNSVIEW 1972**

## DAILY BRIGHT SUNSHINE

1941-1970

by

B.J. Yorke and G.R. Kendall

Normal values of daily bright sunshine for each month and the year, based on the period 1941 to 1970, are listed in this circular. The data replaces the values given in Climatic Normals Volume 3, which were based on the period 1931 to 1960, as the most up to date Canadian bright sunshine data.

The observations summarized in this circular were made with the Campbell-Stokes sunshine recorder in which the sun's rays are focused on a suitable card by means of a glass sphere burning a track along the path of the sun's image. In comparing the values in these tables with sunshine values from United States stations it should be noted that the Marvin sunshine recorder used in the U.S. is an electrical instrument which records the length of time total radiation exceeds a certain threshold value. As the total radiation includes a contribution from the sky as well as that from the sun the measurements are not strictly comparable with those from the Campbell-Stokes. The difference varies but along the Canada-United States border average monthly totals from the Marvin instrument are a fraction of an hour less in November, December and January, but are about an hour greater during the summer season from April to September.

There is no simple relationship between the duration of bright sunshine and the amount of radiation occurring at any station because of varying solar elevation angles and other factors.

In the tables the length of record used is indicated by a code figure in the right hand column headed "Type of Normals". The code is as follows:

1. Normals computed from a period of record of 30 years from 1941 to 1970
2. Normals computed from 10 to 29 years of record within the period 1941 to 1970
3. Averages were computed from less than 10 years of record within the period 1941 to 1970.

The Maps - The map showing total hours of sunshine in the summer months is indicative of conditions during the part of the year when outdoor activity is greatest. The maximum values occur in the southern prairies where totals for the five months exceed 1400 hours, an average of just over nine hours a day. Totals almost as high are found as far north as the mouth of the Mackenzie. In higher latitudes the possible duration of sunshine is greater than in the south but the cloud associated with open water prevents sunshine totals from getting as large as those on parts of the mainland. The lowest totals are found over Hudson Bay and adjacent parts of northern Quebec. On the Island of Newfoundland available stations show totals less than 900 hours but there would probably have been higher values at inland stations if observations had been made.

For the year as a whole all parts of the country have about the same number of possible hours of sunshine, (except for variations in the amount of time the sun is below the height it must reach to produce an indication on the sunshine recorder). Annual sunshine correlates highly with the mean cloud amount in daylight hours averaged over the year and the annual maps show a similar pattern. The greatest annual sunshine totals are found in the Prairie Provinces where they range from 2000 to 2400 hours per year. The lowest sunshine totals are along the Pacific coast just below the Alaskan panhandle where the range is from 1200 to 1400 hours per annum. Sunshine totals are not much greater than this over Hudson Bay and the adjacent parts of Quebec while in the Maritime Provinces, despite the presence of the ocean surface, totals range around 1800 hours, only slightly below those in southern Quebec and Ontario.
