CHAPTER I

SOYBEANS IN CANADA - PAST, PRESENT AND FUTURE

Based on an Article by

Dr. H. Voldeng
Agriculture Canada
Ottawa, Ontario

The soybean (botanically Glycine max (L.) Merrill) is an annual legume which has been cultivated in the Orient for at least 3,000 years. The most recent authoritative reference (Hymowitz, 1970) places its earliest domestication around the 11'th century B.C. in the eastern half of North China. The progenitor of the cultivated soybean (Glycine soja) is a vine-like plant with small black seeds that still grows in the wild state in China, Japan, Korea, Taiwan, Manchuria and adjacent areas of the Soviet Union. The cultivated soybean was introduced from North and Central China to Korea and Japan during the period from 200 A.D. to 300 B.C.

Introduction of Soybeans to Canada

The introduction of soybeans to Canada followed that in the United States, with the first beans grown at the Ontario Agriculture College, Guelph, in 1893 by C.A. Zavitz. Over the next 30 years Zavitz continued to evaluate soybean introductions for yield and maturity and to determine optimal dates of planting, row width and seeding rate. In 1924 he released the variety OAC 211, the first soybean variety registered in Canada. The crop became important in Ontario because of the demand for oil created by World War II, the same demand that resulted in the large expansion of U.S. production. Prior to 1942 10,000 to 20,000 acres were grown annually with about half of it for hay. The first crushing plant was built at Chatham in 1934, and remained viable for only a few years. During the late 1930's the only market for seed was either the linseed processing plant of Maple Leaf Mills or Toronto Elevators. In 1944, spurred by the demand for oil caused by the war, the large Victory Soy Mills plant was erected in Toronto. The company launched a very active campaign to promote the crop and the area in production increased to 254 000 acres by 1954.

Importance of the Soybean

Soybeans are the most important single source of fats and oils in the world, accounting for an estimated 40 per cent of edible vegetable oil production in 1979, and 22 per cent of all fat and oil production if palm oils, industrial oils, animal fats and marine oils are also included. In the protein meal market soybeans are even more dominant, contributing 61 per cent of world production in the crop year 1977/78. The major producing countries with estimated 1978/79 production (tonnes) figures are:

United States	50 149 000
Brazil	11 000 000
China	10 500 000
Argentina	3 500 000
Soviet Union	650 000
Indonesia	500 000
Canada	475 000
Europe	460 000
Other Countries	2 307 000
<hr/>	
Total	79 541 000

(Source: Soybean Digest Bluebook, 1979)

The United States dominates world trade in soybeans and soybean products. In the last three years Brazil, and to a lesser degree Argentina, have become significant factors in the market. Almost all of the Chinese production is utilized domestically. Canada produces slightly more than one-half of one per cent of the total world production.

Utilization

The seed of the soybean must be split into its two most valuable components, oil and protein, if its full value is to be obtained commercially. The seed on a moisture-free basis contains about 20 per cent oil, 40 per cent protein, 30 per cent carbohydrate, 5 per cent fibre and 5 per cent ash. The oil is extracted using the solvent hexane. The residual after oil extraction (meal) contains 44 per cent protein. If the seed coats are removed mechanically before solvent extraction the meal will contain 49 per cent protein. The meal is steam "toasted" as it leaves the solvent extractor to vaporize the hexane and to destroy anti-nutritional factors. Raw soybeans contain a number of anti-nutritional factors that inhibit the growth of monogastric animals. The principal such compound is soybean trypsin inhibitor. It is readily inactivated by moist heat.

The soybean oil after refining is used to produce salad oil and salad dressings. After partial hydrogenation, bleaching and deodorization more stable salad oils are produced as well as special shortenings and margarine oils. Soybean oil is often blended with other oils to produce products with special properties. Once refined the principal vegetable oils are largely interchangeable and price and availability will dictate which is used. Food uses account for 93 per cent of U.S. soybean oil utilization, industrial uses only 7 per cent. Soybean oil is used in paints, varnish, resins, plastics and other drying oil products as well as for soap manufacturing. Petroleum-based products have captured many markets where soybean oil could be used.

A by-product of soybean oil is lecithin, the oil-phosphatide mixture obtained after degumming. Soybean lecithin is used as a food emulsifier, wetting agent and antioxidant. It is added in small amounts in chocolate, cocoa, candies, margarine, cake mixes, ice cream and instant and baby foods. Lecithin is widely used in the pharmaceutical industry as an emulsifying agent.

Soybean meal is used almost entirely as a protein feedstuff for livestock. About 3 per cent of the meal is used directly in human foods. Soybean protein is relatively high in the essential amino acids lysine, leucine and isoleucine which are low in cereal proteins. Therefore soybean protein can be used very effectively to supplement cereal proteins. Soybean protein is somewhat low in the sulfur-containing amino acids cystine and methionine. Fortunately cereal proteins are relatively high in these amino acids.

The 49 per cent protein meal was developed for poultry rations. It is used in rations for young pigs. The 44 per cent meal is used mainly for older pigs and for cattle. In cattle feeding urea is increasingly used in place of much of the soybean meal. Other protein sources - meat meal, fish meal, rapeseed meal - may be in part substituted for soybean meal. As with vegetable oils, price and availability often dictate which source is used.

Food Uses of Soybeans

The crop was, and to a considerable degree still is, grown in the Orient to be utilized directly in various food products. The seeds of the soybean are used to prepare a wide range of foods that supply a major part of the protein in the diet of the people of these countries. Some of these oriental foods are becoming available in Canada and it is of interest to describe them in some detail.

Soy Milk - the soaked beans are ground with ten parts water, boiled to reduce the beany, bitter flavour and the solid residue separated from the liquid (milk).

Tofu - the protein in soymilk is precipitated to form a cheese-like curd.

Sufu - sterilized tofu is inoculated with a fungus and incubated for three to seven days.

Miso - cooked soybeans are mixed with cooked rice, wheat or barley containing the fungus Aspergillus oryzae and fermented for about two months.

Soy sauce - cooked soybeans are combined with ground wheat, inoculated with Aspergillus oryzae, yeast and lactic acid bacteria and fermented for about five days. Salt is added and the mixture fermented in large vats for three to 12 months. The mash is strained to give soy sauce.

Tempeh - an Indonesian food prepared from cooked soybeans or soybean grits incubated with a mold Rhizopus oligosporus.

Hamanatto - whole cooked beans are mixed with wheat flour and inoculated with Aspergillus oryzae. The fermented beans are packed with salt, spice, wine and water and aged for several months.

Natto - whole cooked soybeans are inoculated with the bacteria Bacillus natto and incubated at 40°C for 12 to 20 hours. The product is sold in the incubation package and must be used almost immediately.

These processes change the somewhat unpalatable, bland tasting soybean into a rich diversity of foods. The various fermentations with microorganisms increase the availability and digestability of the nutrients in the soybean seed.

In Canada, a small amount of soybeans or soybean meal is used directly for human consumption. Soybeans can be the sole source of proteins for humans if supplemented with synthetic methionine. Small amounts of cereal or meat protein will also supply the necessary methionine. However, soy protein is seldom used alone.

Four main products are produced. Full fat flour (40 per cent protein) is made from beans with only the hulls removed. Defatted flour (50 per cent protein) is made from meal after the oil has been extracted. Soy protein concentrates (70 per cent protein) are made from meal from which the carbohydrates have been removed by extraction with aqueous alcohols or dilute acids. Soy protein isolate (more than 90 per cent protein) is made by extraction of the protein with dilute alkali followed by precipitation of the protein in dilute acid.

Some protein is lost in this process and soy protein isolates cost at least five times as much per pound as soy flour.

Very little soy protein is used "as is". Most is added to other foodstuffs to improve their functional properties, i.e. to improve fat or water absorption. Soy flour is added to baked goods (bread, cakes, cookies, pancake mixes) at rates of 4-5 per cent. Processed, prepared and canned meat products take the second largest amount of soy protein.

Textured soybean protein is often mentioned as a replacement for meat. It is made either by extrusion starting with soy flour, or by forming fibres of coagulated protein starting with soy protein isolate. These products have a fibrous texture and "chewiness" and with appropriate flavours they can be made into simulated meat.

Soybeans in Ontario

Soybeans are Ontario's fourth most important cash crop in terms of dollar value, coming after tobacco, vegetables and grain corn. Production is concentrated in southwestern Ontario. The major producing counties, and their acreage in 1978 were:

Essex	192 000
Kent	205 000
Lambton	170 000
Elgin	63 000
Middlesex	40 000
Other	7 000
<hr/>	
Total (Ontario)	705 000

The Ontario crop since 1949 has been marketed under terms negotiated on behalf of the producers by the Ontario Soya-Bean Growers' Marketing Board. The Board determines each year with soybean processors and dealers the terms and conditions of sale. These include such matters as moisture discounts, handling and cleaning charges. The price of Ontario beans is determined by and is similar to the Chicago price, with allowance for the cost of transportation and relative currency values.

The Ontario grown soybeans are processed at three plants: Victory Soya Mills (owned by Proctor and Gamble) in Toronto, Canadian Vegetable Oil Processing Limited (owned by Canada Packers) in Hamilton and the recently completed Maple Leaf Monarch plant (affiliated with Unilever Corporation) in Windsor. The CSP Foods Plant in Altona, Manitoba, has in some years crushed limited amounts of soybeans imported from the U.S. Total crushing capacity in Ontario is about 35 million bushels per year.

Soybean acreage in Ontario has increased from 390 000 acres in 1975 to 705 000 acres in 1978. However, this expansion has been almost entirely in the five southwestern counties where soybeans were already grown. With the availability in 1979 of limited seed supplies of the early varieties Maple Arrow, McCall and Evans a significant amount of soybeans was produced in southern and western Ontario, and to some degree in central and eastern Ontario. This trend is expected to continue in 1980. These varieties require 2,550 to 2,700 Corn Heat Units to mature and in a number of cases have produced exceptional yields in the "fringe" areas. They are certainly superior to earlier short season varieties. Coupled with new types of granular inoculant for fields that have not grown beans before, narrower rows and improved harvesting equipment, they are expected to lead to a steady increase in production outside of the five southwestern counties. However, there is the potential for an additional 200,000 acres in southwestern Ontario according to a recent Marketing Board study (Potential Soybean Acreage in Ontario) if soybeans offer a higher return than grain corn or winter wheat.

Development of Short Season Varieties

The justification for the effort to develop a large acreage of soybeans outside of southwestern Ontario has been the magnitude of imports of soybeans, meal and oil. This has been and continues to be sizeable. The situation is outlined below for the 1977/78 crop year.

<u>Whole Soybeans</u>	<u>Quantity (tonnes)</u>
Production	527 361
Imports	262 835
Exports	64 173
Domestic Crushing	728 400
<u>Soybean Oil</u>	
Imports	28 100
Exports	1 400
Domestic Production	125 600
<u>Soybean Meal</u>	
Imports	376 300
Exports	45 600
Domestic Production	575 400

(Source: Fats and Oils in Canada, Annual Review, 1978)

Looked at in terms of dollars (for the calendar year 1978) the import/export figures are heavily in favour of imports.

Raw Soybeans	\$ 91 245 000	\$ 24 375 000
Oil	19 070 000	742 000
Meal	103 093 000	12 436 000
<hr/>		
Total	\$ 213 408 000	\$ 37 553 000

(Source: Fats and Oils in Canada, Annual Review, 1978)

This is not a new situation. For many years Canada has imported large quantities of soybeans and soybean meal. An encouraging development in 1978 and 1979 has been a significant rise in exports of whole soybeans to the Orient for use in soybean foods such as tofu. Exports to Hong Kong, Japan and Singapore amounted to 62 258 tonnes in 1978 and are expected to be higher in 1979.

Give the incentive to reduce imports by producing more soybeans in Canada, why has the crop not become established outside of southwestern Ontario? To establish a crop in a new area one must first of all have a considerable economic incentive, either in the form of high returns from the new crop or, as has often been the case in Canada, the inability to market the total production of an established crop. There must also be in place, or follow soon after, an efficient system to collect the crop and move it to where it is processed or exported. And, since no crop remains unusually profitable for very long, it is essential that well adapted, high yielding varieties and efficient agronomic techniques be developed to bring about the maximum yield of the crop.

Today in Ontario in the 2,500 to 2,800 Corn Heat Unit area that borders the traditional five county region, interest in soybeans is high, elevators are collecting the crop and crushing plants are within fairly close proximity. In this area soybeans should become an established crop. Eastern Ontario and southwestern Quebec have the potential to produce yields comparably to those in the expansion areas bordering the established production region. Unfortunately, there are no crushing plants closer than Toronto. Country elevators are accepting soybeans for shipment to Toronto but unless returns for soybeans remain very high the interest in the crop will decline as it did in the past.

Soybeans in Quebec and the Maritimes

The remainder of Eastern Canada imports, either from Ontario or from the U.S., considerable quantities of soybean meal and smaller quantities of soybean oil. Soybeans could be grown and fed whole to replace part of the soybean meal. For ruminants no special processing is required. Several hundred acres of soybeans are grown each year in Quebec south of Montreal and fed to dairy cattle. Uncooked soybeans cannot be mixed with the urea often used in ruminant rations as a source of protein-nitrogen. Poultry and hogs require the whole beans to be heat-treated to destroy the trypsin inhibitor they contain. If this is done the soybeans can substitute completely for the equivalent protein in soybean meal. The oil in the whole beans results in soft fat on the finished hogs and in the final few weeks of fattening whole beans should be replaced by soybean meal. Propane-fired roasters and tractor-driven extruders are available to destroy the trypsin inhibitor in whole beans. The latter have been used successfully on a small scale in both Nova Scotia and New Brunswick.

Soybeans as an on-the-farm protein source are attractive where protein meal prices are high, or when the price of oil drops to a level at which it is not economically profitable to extract it from the soybeans. Many hog and poultry producers have close associations with feed supply firms and choose to buy protein meal rather than produce their own. Others do not wish to take time and expertise away from their livestock operations and devote it to growing soybeans. The marketing system is not in place to facilitate the transfer of whole beans from cash crop growers to livestock producers.

Experimental lines of soybeans are available with protein and oil contents of 45 and 16 per cent instead of the usual 40 and 20 per cent. However, yields are not equal to high-oil beans. If yields of such lines are improved whole soybeans might become a viable feedstuff in areas distant from crushing plants.

Soybeans in the Prairies

The situation in southern Manitoba and Alberta differs appreciably from that in Eastern Canada. In the Prairies there are farmers prepared to grow specialty crops and transport them long distances to markets. The example of mustard and lentils comes to mind, and rapeseed is often trucked some distance to a crushing plant.

The infrastructure to handle the crop is in place. A number of crushing plants are located in the area, although only that at Altona has processed soybeans in the past. There is also a market for soybean meal: \$36,040,000 in the three Prairie Provinces in 1978. This market has remained remarkably constant since 1974, even though there has been a large increase in rapeseed production and major improvements in the quality of rapeseed meal.

The problem on the Prairies is one of crop adaptation. In the past soybean yields have been variable and generally low. A number of changes have taken place recently that may result in higher and more stable yields. Improve varieties are available. Maple Presto, developed at the Ottawa Research Station of Agriculture Canada, is earlier and of a better plant type than previous very early maturing varieties. It will mature in 95-105 days from planting. The variety McCall from Minnesota, although later than Maple Presto, can be grown in the warmer parts of southern Manitoba. It consistently produces very high yields in its area of adaptation. Both varieties are insensitive to the long hours of daylight in June and July that delay the maturity of most soybeans in northern latitudes. Maple Presto is also relatively insensitive to low night temperatures that delay and reduce pod development. Lastly, both varieties respond well to production in grain drill row widths of seven to 14 inches.

Row width appears to be an important key to satisfactory soybean yields in the Prairies. Improved chemical herbicides obviate the necessity of growing soybeans in wide (30 inch) rows and cultivating to control weeds. Narrow rows produce higher yields and taller plants with the lowest pods higher off the ground. In addition narrow rows "crowd out" late germinating weeds and provide a "shelter-belt" effect within the crop.

Lastly, improved grain drill-type planters developed for narrow row production in the U.S. are becoming available. These should improve stand establishment, often a problem in Manitoba. The new flexible, floating combine cutter heads for soybeans allow pods very close to the ground to be harvested. These will be necessary if growers are to harvest the full potential yield of the crop. For fields where soybeans have not been grown before recently developed granular forms of bacterial inoculant are a reliable means of establishing nodules on the plants and so permitting the crop to produce a significant proportion of its own nitrogen and seeds with high protein levels.

There is diversity in the soybean germplasm to overcome some of the problems still remaining. There are more drought-tolerant strains, and lines that carry the lowest pods higher off the soil. Research in Wisconsin and France suggests that other lines are able to germinate at lower soil temperatures. It will be several years before these can be fully evaluated and incorporated into early varieties. In the future it is possible that the new varieties and those that may be released in the next two years, together with new agronomic practices and equipment, and coming at a time of high nitrogen prices and large supplies of wheat, may form the basis for a sizeable area of soybean production on the Prairies.

CHAPTER 2

WORLD PRODUCTION AND TRADE IN OILS, FATS AND MEALS

World Oils and Fats: Calculated Production

World production of oils and fats in 1980 is forecast to increase by approximately 10 per cent to 59.2 million tonnes, compared to 54.9 million tonnes in 1979.

All categories of oils and fats show projected increases in 1980, but the main portion of the increase is accounted for by the edible vegetable oil sector which is shown rising from 30.0 million tonnes in 1979 to 33.2 million tonnes in 1980.

Major Oils and Fats: World Production, Disappearance and Stocks

According to Oil World, opening stocks of oils and fats, along with production, total supplies, disappearance and ending stocks, all show increases for the 1979/80 period. The order of magnitude of these increases is about four per cent.

World Production of Oilmeals

Oil World is estimating the world production of oilmeals increased by about five per cent in 1978/79 compared to the preceding year. The major portion of the increase is attributable to soybean meal, the production of which went from 50 959 000 tonnes in 1977/78 to 54 678 000 tonnes in 1978/79.

CHAPTER 3

CANADIAN OILSEED PRODUCTION, PROCESSING AND TRADE IN FATS AND OILS

Canadian Oilseeds: Area, Yield, Production

Rapeseed production increased slightly in 1979 due to a larger seeded area. The yield declined slightly and the total production was only slightly more than in 1978.

Flaxseed production increased sharply to 835 700 tonnes due to a larger seeded area. The average yield declined by about 10 per cent compared to 1978.

Soybean production increased due to a slightly larger seeded area coupled with an excellent average yield.

Sunflowerseed production nearly doubled in 1979 due to an increase in seeded area.

Mustardseed production declined in 1979 in line with a decreased production area and a lower average yield.

Canadian Oilseed Processing

There were increases in the volume of oilseeds processed in Canada in the crop year 1978/79 compared to the previous crop year. Rapeseed showed a large increase to 725 100 tonnes. Soybeans showed a smaller increase to 742 600 tonnes. Data for flaxseed and sunflowerseed is not available.

Canadian Imports of Fats and Oils

Imports of edible vegetable oils declined in 1979, reflecting the increased availability of domestically - produced rapeseed and soybean oils. Total fats and oils imports declined to 129 607 tonnes in 1979, compared to 149 469 tonnes in 1978.

Canadian Exports of Fats and Oils

Exports of edible vegetable oils increased in 1979, mainly because of larger rapeseed oil exports. Total exports of 307 961 tonnes included 149 267 tonnes of inedible tallow.

FOOTNOTES TO

CANADIAN EXPORTS OF FATS AND OILS

- 1/ Butter exports have been converted to oil equivalent, using the factor of 81%.
- 2/ This class includes both edible and inedible tallow. The proportions are not known.
- 3/ Marine oil exports listed under "Inedible Oils" include sun-rotted cod liver oil, a non-specified group of fish and marine oil, and fish liver and visceral oils. While most of these oils can be assumed to be of an inedible grade, a small quantity of edible soy may have been included.

CHAPTER 4

THE CANADIAN RAPESEED SITUATION

Canadian Rapeseed Production

In response to market demand and favourable prices, rapeseed production in the crop year 1978/79 reached a record level of 3 497 100 tonnes, almost double the previous year's production. Starting stocks were up slightly from the previous year.

Domestic crushings increased over the previous year as did exports of seed and oil, but exports of rapeseed meal dropped approximately 5 per cent to 162 500 tonnes.

Exports of Rapeseed

Exports of rapeseed increased approximately 65 per cent to 1 988 267 tonnes. Japan purchased 1 157 771 tonnes, and was again our major market.

Exports of Rapeseed Oil

Exports of rapeseed oil for 1979 were 4 597 tonnes above 1978 level of 114 879 tonnes. India received over 70 000 tonnes while Chile, Japan, Algeria and Hong Kong were also important markets.

Exports of Rapeseed Meal

Although exports of rapeseed meal declined approximately 5 per cent, to 162 500 tonnes in 1979, the value of the rapeseed meal increased 11 per cent over 1978 levels to \$27,931,000.

CHAPTER 5

THE CANADIAN SOYBEAN SITUATION

Supply and Disposition - Soybeans

Canadian production of soybeans in 1979 was 671 700 tonnes compared to 475 134 tonnes in 1978. For the crop year 1978/79, soybean imports amounted to 350 400 tonnes, exports were 90 900 tonnes and the domestic crush volume was 742 600 tonnes.

Soybean Oil

Imports of soybean oil declined during the 1978/79 crop year, exports increased slightly, and domestic production showed a small increase to 129 000 tonnes.

Soybean Meal

Imports of soybean meal increased sharply in 1978/79 to 480 300 tonnes versus 376 300 tonnes in 1977/78. Exports of soybean meal declined, and the domestic production was virtually unchanged at 576 700 tonnes.

CHAPTER 6

THE CANADIAN FLAXSEED SITUATION

Flaxseed Production

Flaxseed production for 1979 was 835 700 tonnes, an increase of 46 per cent over 1978 production of 571 500 tonnes. During 1979 seeded area increased but average yields decreased.

Exports of Flaxseed

Exports of flaxseed increased by 125 408 tonnes over 1978 to 534 825 tonnes in 1979. The value of these shipments increased by approximately 64 per cent during the same period. As in previous years, Japan and Europe were our major markets.

Exports of Linseed Oil and Meal

Exports of linseed oil decreased by 3 449 tonnes during 1979 to a level of 4 650 tonnes. Similarly, exports of linseed meal decreased to 4 518 tonnes in 1979, from 5 583 tonnes in 1978.

CHAPTER 7

THE CANADIAN SUNFLOWERSEED SITUATION

Sunflowerseed Production

Manitoba was again Canada's leading producer of sunflowerseed accounting for 95 per cent of total production. In 1979 production increased by more than 100 000 tonnes from 1978 to a record level of 220 900 tonnes.

Exports of Sunflowerseed

Exports of unprocessed sunflowerseed continued to increase in 1979 to a level of 89 231 tonnes, 15 112 tonnes higher than in 1978. West Germany and the USA continue to be the principal markets. Total value of the 1979 exports of sunflowerseed was \$25,757,000.

CHAPTER 8

THE CANADIAN MUSTARDSEED SITUATION

Mustardseed Production

Production of mustardseed dropped to 53 300 tonnes in 1979 from 103 448 tonnes in 1978. Our exports of 67 388 tonnes in 1979 were mainly to the traditional markets in Europe, Japan and the USA.

Imports of Ground Mustard

The United Kingdom continues to be Canada's major supplier of ground mustard, accounting for over 80 per cent of our 267 tonnes imported during 1979.

CHAPTER 9

DEODORIZED FATS AND OILS

Canadian production of deodorized oils in 1979 increased by approximately 12 per cent, with deodorized vegetable oils accounting for most of the volume increase. Rapeseed oil usage continued to increase, particularly for shortening and salad oil.

Imports of vegetable oils and fats (NES) decreased sharply, from 3 235 tonnes in 1978 to 2 032 tonnes in 1979. Cocoa butter imports showed little change, coconut oil increased marginally, and corn oil imports declined. Imports of cottonseed oil, olive oil, palm oil and peanut oil declined, while palm kernel oil imports increased.

Exports of vegetable oils and fats (NES) doubled in 1979 to 7 220 tonnes.

CHAPTER 10

SPECIFIED FATS AND OILS

According to Statistics Canada, Canadian margarine production recovered in 1979 to 128 000 tonnes, while butter output declined to 103 000 tonnes.

Data is no longer published by Statistics Canada on lard and tallow production; therefore, the table on Canadian production of specified fats and oils products no longer includes the production of lard, edible tallow and inedible tallow.

Table 50

^{1/} Includes retail and commercial packages. Commercial sales (21-450 pound) packages account for about 5% of total output.

^{2/} Includes creamery and whey butter.

^{3/} Retail packages up to 20 pounds only.

^{4/} Covers commercial (21-450 pound) packages, bulk and other than packaged retail sales of manufacturers of shortening and deodorized shortening oil. Includes baking and frying fats and oils.

^{5/} Covers packaged sales only.

CHAPTER 11

FISH AND MARINE OILS AND MEALS

Canadian Trade of Fish and Marine Oils

Exports of these oils increased in volume terms in 1979, although the value decreased slightly to \$4.4 million. Imports of these oils in 1979 fell to less than one-half of the 1978 volume.

Canadian Trade of Fish Meal

Exports of fish meal and condensed solubles decreased in 1979 to 26 138 tonnes, valued at \$12.5 million. Imports were insignificant at 308 tonnes, valued at \$111,000.

Canadian Production of Fish Oils and Meal

The statistical tables to show the Canadian production of fish oils and meal were of necessity not included in this publication. The reason for their deletion is the fact that Pacific Coast production data cannot be released because in some product areas less than three companies are involved.

CHAPTER 12

OTHER INEDIBLE FATS AND OILS

The products grouped in this chapter are castor, tung and tall oils, tall oil pitch, tall oil fatty acids, chemically modified oils, fats and waxes, and mixtures and derivatives of oils, fats and waxes.

Imports of castor oil increased slightly in 1979 to 1 721 tonnes. Tung oil imports fell slightly in volume terms, and by a large amount in value terms. Imports of tall oil, tall oil pitch and tall oil fatty acids increased marginally in volume terms.

Imports of chemically modified oils, fats and waxes dropped sharply to 3 791 tonnes versus 7 865 tonnes in 1978.

Imports of mixtures and derivatives of oils, fats and waxes increased in 1979 compared to the previous year.

Canadian exports of chemically modified oils, fats and waxes declined by about 25 per cent in volume terms, although the dollar value increased in 1979 over 1978.
