St. John's, Newfoundland
AIC $5 \times 1$

ABSTRACT
Catch and effort data from the 1980 northern Labrador Arctic charr fishery are presented. Landings decreased from the previous year by $4 \%$ and totalled 204 MT. The concentration of fishing in the Nain-Okak region appears to have reduced the proportion of larger sized fish in the commercial landings. Results of yield per recruit analyses indicated that catch rates in several areas should be reduced.

RESUME
On trouvera ici les données sur les prises et l'effort de pêche pour l'omble chevalier au Labrador septentrional en 1980. Les débarquements de 204 tm sont de $4 \%$ infērieurs à ceux de l'année précédente. Il semble que la concentration de la pêche dans la région de Nain-0kak ait causé une diminution de la proportion des grands poissons dans les débarquements commerciaux. Des analyses de rendement par recrue indiquent que les taux de capture devraient être réduits dans plusieurs régions.

## INTRODUCTION

Northern Labrador Arctic charr stocks were previously evaluated by the Beverton and Holt yield per recruit model based upon data collected during 1977 (Dempson 1978). The assessment indicated that several charr stocks in the vicinity of Nain, Labrador, were being overexploited while stocks further north remained underfished. Total annual mortalities in excess of $55 \%$, in addition to the change in size composition of several populations (Dempson 1978), led to the establishment of quotas on Voisey, Anaktalik and Tikkoatokak Bays for the 1979 season. These quotas remained in effect for 1980 and were: Voisey Bay-22.5 MT; Anaktalik Bay-21.5 MT; Tikkoatokok Bay-39.5 MT.

Sufficient data are still lacking to perform virtual population analyses, therefore this document reassesses various charr stocks in the Nain fishing region (Fig. 1) using the yield per recruit model based upon data from 1977 to 1980.

## MATERIALS AND METHODS

The Nain fishing region outlined in Fig. 1 was subdivided on a geographical basis into various bays and fiords in order to calculate separate catch and effort statistics (Fig. 2) (Coady and Best 1976; Dempson 1978). Catch and effort data were available from 1974 to 1980 while total Labrador production was available since 1942 (Coady and Best 1976; Dempson 1978). Commercial sampling for size and age composiion of individual stocks has been carried out since 1977.

Total instantaneous mortality rates were derived in two ways: catch curves, using age frequency data from 1977-80, and by the Paloheimo method (Ricker 1975) where catch per unit effort at age data are required. A natural mortaity rate of 0.17 was used in this assessment. This value was based on an estimate by Moore (1975) for an unexploited anadromous charr population in the Cumberland Sound area of Baffin Island.

The Beverton and Holt yield per recruit model was applied to the Tikkoatokak Bay charr stock using the parameters listed in Table 1. The method of Thompson and Bell (Ricker 1975) was applied to Voisey and Okak Bay stocks. Mean weight at age was obtained from commercial sampling data and partial recruitment values were derived from a matrix of fishing mortality values generated from a cohort analysis (Rivard 1980).

## RESULTS AND DISCUSSION

## CATCH AND EFFORT STATISTICS

Landings of Arctic charr decreased by 4\% to 204 MT during 1980 (Fig. 3). Effort similarly declined by approximately 4\%. Part of this decline can be attributed to the successful salmon fishery in the area which effectively removed some of the effort normally directed toward specific charr stocks. Quotas during the past two seasons may have also resulted in a slight change in the distribution of fishing effort. Both effort and apparent abundance of charr has increased in the outer island areas of Dog Island, Black Island and

Kiglapaits during the past two fishing seasons (Table 2). Tikkoatokak Bay remained the most exploited area with 175 MT of charr having been removed during the past 4 years (Table 2). Landings from this area in 1980 contributed $25 \%$ of the total catch within the Nain fishing region.

## SIZE COMPOSITION

Size composition of commercial landings appears to have been altered from the concentration of fishing in the Nain-Okak area. Table 3 lists the size breakdown of commercial landings at the Nain Fish Plant for the period 1970-80. The proportion of charr under 2.3 kg (gutted head on weight) has increased from 75 to $88 \%$ since 1977.

With respect to individual stocks, the five areas with the greatest landings during the past 5 years (Tikkoatokak, Okak, Voisey, Cutthroat, Anaktalik) have undergone substantial changes in size composition of their landings. Whereas landings for those areas in 1976-1977 had approximately $30 \%$ of the charr over 2.3 kg , in 1980 less than $12 \%$ of the catch was composed of these larger charr (Table 3).

## YIELD PER RECRUIT ANALYSIS

Numbers at age in the commercial catch and total instantaneous mortality rates derived from the Paloheimo method are outlined in Table 4. Total instantaneous mortality rates in Tikkoatokak, Voisey and Okak Bay were $0.78,0.79$ and 0.69 respectively. Due to the considerable variation in these mortality rates, yield per recruit analyses were also carried out using mortality estimates derived from catch curves. The latter estimates, however, represent mortality rates in effect during the period of time these fish were recruited into the fishery (Ricker 1975) but are assumed to represent current conditions in this analysis. These rates were 0.68 for Voisey Bay, 0.83 for Tikkoatokak Bay and 0.48 for Okak Bay (Fig. 4). Differences between the two mortality rates in relation to effort changes are indicated in Table 5. In comparison, total instantaneous mortality derived from age frequency data from experimental fishing carried out in the Hebron area during 1980 was 0.32.

Results from the yield per recruit analyses are summarized in Table 6. Landings of Arctic charr for Okak Bay were relatively close to the level suggested by fishing at $\mathrm{F}_{0.1}$. If catch curve mortality rates are used, landings could increase by approximately $40 \%$ over the 1980 level. Rate of fishing in Voisey and Tikkoatokak Bay is in excess of the optimal mortality rates, although the catch curve rate of fishing mortality in Voisey Bay would yield landings closer to the level indicated by fishing at $\mathrm{F}_{0 \cdot 1}$.

The Hebron Fiord has been virtually unexploited since 1969. Efforts to initiate fishing in this area in 1981 appear promising at the present time.

## SUMMARY

1. Landings of Arctic charr in northern Labrador decreased by approximately $4 \%$ to 204 MT during 1980. Total effort similarly declined by the same amount.
2. The Tikkoatokak Bay area remained the most exploited area again in 1980 with landings representing $25 \%$ of the total catch in the Nain fishing region.
3. Considerable changes in the size distribution of landings has occurred in several areas since 1976.
4. Rate of fishing in Voisey and Tikkoatokak Bay exceeded optimal levels as indicated by the yield per recruit analysis. Fishing in Okak Bay is at an acceptable level while northern areas still remain unexploited.
