1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the timeframes required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte Atlantique du Canada. Comme tel, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de Recherche qu'elle contient ne doivent pas être considérés comme étant des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur des études en cours.

Les Documents de Recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

Catch and effort statistics for the Labrador commercial and recreational Atlantic salmon, Salmo salar, fisheries are summarized. Landings in the commercial fishery for 1982 decreased by 33% from 1981 and totalled 543 t. Recreational harvest dropped by 17% to 4725 fish although more large salmon were taken in the 1982 recreational fishery. There is some evidence to suggest that the river age of the Labrador multi-sea-winter catch has been declining with time.

Résumé

On résume les statistiques sur les prises et l'effort de pêche de saumons atlantiques (Salmo salar) dans les pêches commerciales et sportives du Labrador. Les débarquements de pêche commerciale en 1982 ont diminué de 33 % par rapport à 1981; ils se chiffraient au total à 543 t. Les prises de pêche sportive ont baissé à 4725 saumons, soit une diminution de 17 %, mais on a capturé un plus grand nombre de gros poissons en 1982. On a des raisons de penser qu'au Labrador les poissons qui ont passé plusieurs hivers en mer et qu'on capture dans les rivières sont de plus en plus jeunes.

Introduction

This paper summarizes catch and effort statistics for the Labrador commercial and recreational Atlantic salmon, *Salmo salar*, fisheries. Catch data and contributions of grilse and salmon to both fisheries are examined in comparison with trends in recent years. Commercial sampling data from the Labrador fishery were examined to detect changes in the proportion of 1-SW, multi-sea-winter and previous spawners of varying river age.

Catch and Effort Statistics

Commercial fishery

Catch statistics from the Labrador commercial salmon fishery have been available since 1952 (Table 1). Commercial salmon landings have undergone a gradual increase that peaked at 756 t in 1976 (Fig. 1). This was followed by a substantial decline during the next three years ending in 1979 with the lowest catch and catch per unit effort in twenty years (326 t). Both catch and catch per unit effort increased substantially in 1980. Landings of 853 t were the highest on record for the Labrador fishery. While the 1981 fishery declined slightly to 813 t, landings in 1982 decreased by 33% to 543 t. The 1982 catch was also 14% lower than the previous 5-year mean of 628 t. Effort increased slightly resulting in a decrease in catch per unit of effort by 35%.

Statistical sections 51 and 52 again contributed 76% of the total Labrador catch (Table 2). Landings, however, were 45% lower in section 52 while decreasing by 19% in section 51. Landings in sections 50 and 53 decreased by 13% and 43% respectively.

Recreational fishery

Reduced catches also occurred in the 1982 Labrador recreational fishery (Table 1, Fig. 2). A total of 4725 fish were reported caught which is down by 17% from 1981. Catch and catch per unit effort decreased in statistical sections 50, 51 and 52 (Table 3). In section 53, catch per unit effort declined but total catches increased by 34% to 1147 (Table 3). Catches in Pinware River (714) and Eagle River (1515) decreased by 42% and 41% respectively (Table 4).

In 1981 the Eagle River catch represented approximately 50% of the reported Labrador recreational salmon catch and together with the Pinware River, contributed 73% of the total catch. During 1982 only 35% of the angled catch came from Eagle River and the combined catch with the Pinware River decreased to 47% of the Labrador total.

Stock Composition

Data pertaining to the proportion of grilse and large salmon in the Labrador commercial fishery have been available since 1969. The large salmon component represented 81% of the catch by weight (64% by number) for the years

1969-78. Since then the abundance of large salmon in the catch has decreased to represent 71% of the catch by weight (51% by number). Proportion of large salmon in the catch in 1982 was virtually identical to that of 1981 (71% by weight, 51% by number). Direct comparisons of 1981-82 data with previous information may be inaccurate owing to changes and variations in size classifications used to grade salmon into small and large categories. Nevertheless, based on catch statistics, there appears to have been a decreased abundance of large salmon during the past several years resulting in lower commercial catches.

With respect to the recreational fishery the large salmon component increased from 9% of the total catch in 1981 ($N = 520$) to 13% in 1982 ($N = 621$). This was largely due to the increase in large salmon recreational catches by 21% on the Eagle River and the reported catch of 249 large salmon on the Hunt River (Table 4). This latter catch from the Hunt River represented 40% of the total reported large salmon recreational catch in Labrador and 59% of the total catch on that river. No information was available for the Hunt River in 1981.

Catches of large salmon decreased on the Forteau River and Pinware River by 39% and 66% respectively (Table 4). The large salmon catch on the Pinware River was the lowest recorded since 1962 (Table 4).

Commercial sampling information was examined to detect changes in the proportion of 1SW, multi-sea-winter and previous spawners of varying river age. These data are summarized by statistical section in Tables 5-7.

The percentage of multi-sea-winter salmon of river ages 2 and 3 range from 8 to 25% in statistical section 51; 4-43% in section 52; and 16-28% in section 53 (Table 5). For the past three years (1979-81) the proportion of river age 2 and 3 salmon caught in statistical section 53 has remained relatively constant while showing an increasing trend in section 52.

For 1SW salmon the percentage of salmon with river age 1, 2 and 3 has varied from 13-39% in section 53 (Table 6). A noticeable difference between 1SW and multi-sea-winter salmon is found in the contribution of river age 1 fish to the commercial catches of 1SW salmon in statistical section 53.

Trends were observed for a decrease in mean river age with time in multi-sea-winter salmon catches in Labrador. A statistically significant correlation for decreasing mean river age with year was obtained for statistical section 52 ($r = -0.805$, $P < 0.01$) and for section 51 ($r = -0.848$, $P < 0.05$) providing the 1969 data were omitted from the latter section. In section 53 mean river age has decreased from 1978-81 although owing to the few years of available data, the relationship was not statistically significant ($r = -0.865$, $P = 0.13$).

Pooling of data from all sections for multi-sea-winter salmon similarly gave statistically significant relationships for decreasing river age with time (1970-81, $r = -0.849$, $df = 6$, $P < 0.01$; 1969-81, $r = -0.702$, $df = 7$, $P < 0.05$).

Although it is possible that the apparent decline in river age was due to sampling bias, it is strongly suggested there has been a decline in the proportion of Labrador origin multi-sea-winter salmon being harvested in the Labrador fishery. This change in river age of commercial salmon catches warrants further examination in order to clarify the biological reasons for this phenomenon.

Station 27 temperature and salinity data (depth 5 m) were used as an index of general environmental conditions in the Labrador Sea area in order to determine whether there were any correlations with the data which might explain the large variation in annual commercial landings, particularly in the large salmon catch (Fig. 3). Since the large salmon component was the dominant catch in the Labrador commercial fishery, multiple regressions were performed using large salmon catch in year $i+1$ as the dependent variable. Grilse catch in year i , January temperature and salinity in year $i+1$, and June temperature and salinity in year $i-1$ were the independent variables. Using catch data from 1969-81, a statistically significant relationship was obtained. Salinity contributed very little to the relationships. Catch of 1SW salmon in year i explained 51% of the variation in 2SW salmon in year $i+1$. January temperatures in the same year as the forthcoming fishery explained 24% of the variation in 2SW catches. The biological significance of the January temperatures are not entirely clear. It is possible that the January temperature is an index of environmental conditions which influence the distribution and subsequent catchability of returning 2SW salmon. June temperatures lagged two years (year $i-1$) may act as an index of marine temperatures during a period of time when smolt class of the large salmon in year $i+1$ migrated to sea. June temperatures in year $i-1$ explained the remaining 7% of the variation.

Figure 3 illustrates the observed and predicted values for the Labrador large salmon catch using the following relationship:

$$\ln Y = 9.19478 + 0.34771 (\ln X) - 0.29590 (T_1) - 0.06060 (T_2)$$

where Y is the large salmon catch in year $i+1$, X is the grilse catch in year i , T_1 is the mean January water temperature (5 m depth) at Station 27 in year $i+1$ and T_2 is the average June temperature (5 m depth) at Station 27 in year $i-1$ ($r^2 = 0.824$, $F = 14.00$, $P = 0.001$). In general, the predicted values follow the general trends in the large salmon catch reasonably well. A prediction for the 1982 large salmon catch of 404 t was only 4.7% different from the actual 1982 catch using data from 1969-81 in the relationship (Fig. 3).

No projections could be made for 1983 since there were no temperatures taken at Station 27 in January of that year. Nevertheless, there is no suggestion that the 1983 commercial fishery will be higher than in 1982. Owing to the apparent low spawning escapements in 1978 and 1979, as evidenced by the low catches in those years, there is some concern that there will be a lower stock abundance in 1984 and 1985.

Despite the problem of the validity of Station 27 data for the Labrador fishery, a further examination of these data and the biological explanation of the use of these temperatures would appear warranted.
