## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

## LIST OF TABLES

Table 1. Landings ( t ) of NAFO Div. 4T herring in the spring and fall fisheries by gear (fixed andmobile) and spawning group (SS = spring spawners and FS = fall spawners). TAC allocationsare also provided. Total catches highlighted in grey indicate years and stocks where the totalcatch exceeded the TAC.23
Table 2a. Commercial herring fishery samples collected, number of fish processed for age ( N ), landings ( t ), and \% TAC landed by gear type (fixed gear and mobile gear), and zone in the spring (April 1-June 30) and fall (July 1-December 31) herring fisheries of NAFO Div. 4T in 2016. These data are used to derive the 2016 catch-at-age and weight-at-age matrices for NAFO Div. 4T herring. ..... 25
Table 2b. Commercial herring fishery samples collected, number of fish processed for age (N), landings ( t ), and \% TAC landed by gear type (fixed gear and mobile gear), and zone in the spring (April 1-June 30) and fall (July 1-December 31) herring fisheries in NAFO Div. 4T in 2017. These data are used to derive the 2017 catch-at-age and weight-at-age matrices for NAFO Div. 4T herring. ..... 26
Table 3a. Summary of 2016 Atlantic Herring Dockside Monitoring Program (DMP) and telephone survey results including number of respondents, mean net length (fathoms), numbers of nets set, percentage of nets of mesh size $25 / 8$ " in the fall fishery, and a comparative index of abundance from 2015 [scale 1 (poor) to 10 (excellent)]. ..... 27
Table 3b. Summary of 2017 Atlantic Herring Dockside Monitoring Program (DMP) and telephone survey results including number of respondents, mean net length (fathoms), numbers of nets set, percentage of nets of mesh size $25 /{ }^{5}$ " in the fall fishery, and a comparative index of abundance from 2016 [scale 1 (poor) to 10 (excellent)]. ..... 28
Table 4. Spring spawner (SS) Atlantic Herring catch-at-age (number of fish in thousands) from the fixed gear fishery in NAFO Div. 4T. A dash indicates no fish of that age were sampled in that year. ..... 29
Table 5. Spring spawner (SS) Atlantic Herring mean weight-at-age (kg) from the fixed gear fishery in NAFO Div. 4T. A dash indicates no fish of that age were sampled in that year. ..... 30
Table 6a. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the fixed gear fishery in NAFO Div. 4T for the North region. A dash indicates no fish of that age were sampled in that year. ..... 31
Table 6b. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the fixed gear fishery in NAFO Div. 4T for the Middle region. A dash indicates no fish of that age were sampled in that year. ..... 32
Table 6c. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the fixed gear fishery in NAFO Div. 4T for the South region. A dash indicates no fish of that age were sampled in that year. ..... 33
Table 7a. Fall spawner (FS) Atlantic Herring mean weight-at-age (kg) from the fixed gear fishery in NAFO Div. 4T for the North region. A dash indicates no fish of that age were sampled in that year. ..... 34
Table 7b. Fall spawner (FS) Atlantic Herring mean weight-at-age (kg) from the fixed gear fisheryin NAFO Div. 4T for the Middle region. A dash indicates no fish of that age were sampled in thatyear.35
Table 7c. Fall spawner (FS) Atlantic Herring mean weight-at-age (kg) from the fixed gear fisheryin NAFO Div. 4T for the South region. A dash indicates no fish of that age were sampled in thatyear.36
Table 8. Spring spawner (SS) Atlantic Herring catch-at-age (number of fish in thousands) from the mobile gear fishery in NAFO Div. 4T. A dash indicates no fish of that age were sampled in that year. ..... 37
Table 9. Spring spawner (SS) Atlantic Herring mean weight-at-age (kg) from the mobile gear fishery in NAFO Div. 4T. A dash indicates no fish of that age were sampled in that year. ..... 38
Table 10a. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the mobile gear fishery in NAFO Div. 4T for the North region. A dash indicates no fish of that age were sampled in that year. ..... 39
Table 10b. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the mobile gear fishery in NAFO Div. 4T for the Middle region. A dash indicates no fish of that age were sampled in that year. ..... 40
Table 10c. Fall spawner (FS) Atlantic Herring catch-at-age (number of fish in thousands) from the mobile gear fishery in NAFO Div. 4T for the South region. A dash indicates no fish of that age were sampled in that year. ..... 41
Table 11. Fall spawner (FS) Atlantic Herring weight-at-age (kg) from the mobile gear fishery in NAFO Div. 4T, fishing regions combined. A dash indicates no fish of that age were sampled in that year. ..... 42
Table 12. Percent of annual fishing days with no gillnet catch of Atlantic Herring as reported from the telephone survey for the main fishing areas in the spring and fall fisheries in NAFO Div. 4T. ..... 43
Table 13. Results of the multiplicative general linear model applied to the fishery catch-per-unit- effort data for the Atlantic Herring spring spawners (NAFO Div. 4T) and fall spawners (by fishing region in NAFO Div. 4T). ..... 43
Table 14. Spring spawner (SS) Atlantic Herring fixed gear age-disaggregated mean catch-per- unit-effort values (number per net-haul) for NAFO Div. 4T. ..... 44
Table 15a. Fall spawner (FS) Atlantic Herring fixed gear age-disaggregated mean catch-per- unit-effort values (number per net-haul) from the North region of NAFO Div. 4T ..... 45
Table 15b. Fall spawner (FS) Atlantic Herring fixed gear age-disaggregated mean catch-per- unit-effort values (number per net-haul) from the Middle region of NAFO Div. 4T. ..... 46
Table 15c. Fall spawner (FS) Atlantic Herring fixed gear age-disaggregated mean catch-per- unit-effort values (number per net-haul) from the South region of NAFO Div. 4T ..... 47
Table 16. Spring spawner (A; upper table) and fall spawner (B; lower table) Atlantic Herring catch-at-age (t) from the fishery-independent acoustic survey in NAFO area 4Tmno. ..... 48
Table 17. Mean standardized age-disaggregated annual catch per unit effort (number per hour) of Atlantic Herring derived from the experimental gillnets in the fall fishery in North, Middle, and South regions of NAFO Div. 4T. A dash indicates no data were available for that region and year ..... 49
Table 18a. Relative selectivity-at-age (proportion) of Atlantic Herring in the NAFO Div. 4T commercial fixed gear fishery for the $25 / 8$ inches gillnet mesh as calculated from the experimental gillnet data ..... 50
Table 18b. Relative selectivity-at-age (proportion) of Atlantic Herring in the NAFO Div. 4T commercial fixed gear fishery for the $23 / 4$ " inches gillnet mesh as calculated from the experimental gillnet data ..... 51
Table 19. Multi-species trawl survey abundance index (median number per tow) of fall spawner Atlantic Herring from the southern Gulf of St. Lawrence, NAFO Div. 4T. The values represent the median from the Monte Carlo Markov Chain (MCMC) posterior distributions for each year and age ..... 52
Table 20. Maximum likelihood estimates (MLEs) of beginning of year spring spawner Atlantic Herring biomass ( t ) for NAFO Div. 4T. Shading indicates values that are not directly estimated by the model. These values are calculated using the average of the five most recent estimates of recruitment rate (recruits/SSB). Note that MLEs may differ slightly from the MCMC medians reported in the text ..... 53
Table 21. Maximum likelihood estimates (MLEs) of beginning of year spring spawner Atlantic Herring abundance (number in thousands) for NAFO Div. 4T. Shading indicates values that are not directly estimated by the model. These values are calculated using the average of the five most recent estimates of recruitment rate (recruits/SSB). Note that MLEs may differ slightly from the MCMC medians reported in the text ..... 54
Table 22. Maximum likelihood estimates of the instantaneous rate of fishing mortality ( $F$ ) by age of spring spawner Atlantic Herring from NAFO Div. 4T. No estimates (na) are available for the 2014 and 2015 year-classes. F6-8 is the abundance-weighted average $F$ for ages 6 to 8 years.55
Table 23. Probabilities of various population states of spring spawning Atlantic Herring from NAFO Div. 4T at the beginning of 2019 and 2020 (for SSB) or 2018 and 2019 (for F) based on projections under various recruitment scenarios (1 - high recruitment, 2 - low recruitment, 3 - mixed recruitment) and at different levels of annual catch. The abbreviation "na" signifies not examined ..... 56
Table 24. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring biomass ( t ) in the North region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model ..... 57
Table 25. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring abundance (number in thousands) in the North region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model. ..... 58
Table 26. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring biomass ( t ) in the Middle region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model ..... 59
Table 27. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring abundance (number in thousands) in the Middle region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model. ..... 60
Table 28. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring biomass ( t ) in the South region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model ..... 61
Table 29. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring abundance (number in thousands) in the South region for NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model. ..... 62
Table 30. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring biomass ( t ) in NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model ..... 63
Table 31. Maximum likelihood estimates (MLEs) of beginning of year fall spawner Atlantic Herring abundance (number in thousands) in NAFO Div. 4T. Shading and "na "indicates cohorts that cannot yet be estimated by the model ..... 64
Table 32. Maximum likelihood estimates of the instantaneous rate of fishing mortality (F) by age of fall spawner Atlantic Herring in the North region of NAFO Div. 4T. F5-10 is the abundance- weighted average F for ages 5 to 10 years. No estimates ("na") are available for the shaded cell. ..... 65
Table 33. Maximum likelihood estimates of the instantaneous rate of fishing mortality ( $F$ ) by age of fall spawner Atlantic Herring in the Middle region of NAFO Div. 4T. F5-10 is the abundance- weighted average F for ages 5 to 10 years. No estimates ("na") are available for the shaded cell. ..... 66
Table 34. Maximum likelihood estimates of the instantaneous rate of fishing mortality (F) by age of fall spawner Atlantic Herring in the South region of NAFO Div. 4T. F5-10 is the abundance- weighted average F for ages 5 to 10 years. No estimates ("na") are available for the shaded cell. ..... 67
Table 35. Maximum likelihood estimates of the instantaneous rate of fishing mortality (F) by age of fall spawner Atlantic Herring in NAFO Div. 4T. F5-10 is the abundance-weighted average F for ages 5 to 10 years. No estimates ("na") are available for the shaded cell. ..... 68
Table 36a. Projections of fall spawning Atlantic Herring biomass (kt) in NAFO Div. 4T and biomass relative to population status objectives, expressed as probabilities, for various annualcatch levels in 2018 and 2019. The same catch is assumed for 2018 and 2019. Spawning stockbiomass (SSB) is the beginning-of-year median estimate from MCMC sampling. LRP is the limitreference point ( $58,000 \mathrm{t}$ of SSB) and USR is the upper stock reference ( $172,000 \mathrm{t}$ of SSB). ... 69
Table 36b. Projections of fall spawning Atlantic Herring fishing mortality rates (F5-10) and probability of exceeding the removal rate reference (F0.1 = 0.32) for various annual catch levels in 2018 and 2019. F5-10 is the average instantaneous rate of fishing mortality for ages 5 to 10 years and values shown are the median estimates based on MCMC sampling ..... 69
Table B1a. Atlantic Herring biomass densities and estimates by stratum and area from the fishery-independent acoustic surveys conducted in 2015 in NAFO Div. 4T ..... 105
Table B1b. Atlantic Herring biomass densities and estimates by stratum and area from the fishery-independent acoustic surveys conducted in 2016 in NAFO Div. 4T ..... 105
Table B1c. Atlantic Herring biomass densities and estimates by stratum and area from the fishery-independent acoustic surveys conducted in 2017 in NAFO Div. 4T ..... 106
Table C1. Atlantic Herring biomass densities and estimates by spawning ground from the spawning ground acoustic surveys conducted in 2015. ..... 113
Table C2. Atlantic Herring biomass densities and estimates by spawning ground from the spawning ground acoustic surveys conducted in 2016 ..... 114
Table C3. Atlantic Herring biomass densities and estimates by spawning ground from the spawning ground acoustic surveys conducted in 2017. ..... 115
Table C4. Number of individual acoustic sampling trips per year and region from the spawning ground acoustic surveys. ..... 116

## LIST OF FIGURES

Figure 1. Southern Gulf of St. Lawrence herring fishery management zones (a - upper panel), Northwest Atlantic Fisheries Organization (NAFO) divisions 4T and 4Vn, where purple represents the North region, blue = Middle region, and green = South region (b-middle panel), and geographic areas used in the telephone survey of the herring gillnet fishery ( c - lower panel).

Figure 2. Reported landings (t) of southern Gulf of St. Lawrence Atlantic Herring (spring and fall spawners combined) by NAFO division (a - upper panel), by gear fleet ( $b$ - middle panel), and by fishing season (c - lower panel), 1978 to 2017. In all panels, the corresponding annual total allowable catch (TAC; t) is shown. For landings by season, the landings in Div. 4Vn were attributed to the fall fishing season. Data for 2016 and 2017 are preliminary.

Figure 3. Estimated landings (t) of the spring spawner component (SS) (left column) and fall spawner component (FS) (right column) of Atlantic Herring from the southern Gulf of St. Lawrence, 1978 to 2017. The upper row (panels a, d) shows the estimated landings by gear type and the proportion of the landings attributed to the fixed gear fleet by spawner component. Also shown in these panels is the TAC for the spawner component (red symbols) for 1991 to 2017. The middle row (panels b, e) shows the estimated landings of herring in the fixed gear fleet that occurred in the spring fishery season (panel b) and the fall fishery season (panel e) as well as the proportion of herring landed in the corresponding fishing season. The lower row (panels $\mathrm{c}, \mathrm{f}$ ) shows the estimated landings of herring in the mobile gear fleet that occurred in the spring fishery season (panel c) and the fall fishery season (panelf) as well as the proportion of herring landed in the corresponding fishing season. For the mobile gear landings by season, the landings in NAFO Div. 4Vn were attributed to the fall fishing season. Data for 2016 and 2017 are preliminary.
Figure 4. Catch-at-age (number of fish) of the spring spawner component of Atlantic Herring from the fishery, all gears combined, in NAFO Div. 4T for 1978 to 2017. The size of the bubble is proportional to the catch numbers by age and year. The diagonal line represents the most recent strong year-class (1991)
Figure 5. Bubble plots of fishery catch-at-age (number of fish) of thje fall spawner component of Atlantic Herring, by region (upper panel North, middle panel Middle, lower panel South) for mobile gear and fixed gear combined, in NAFO Div. 4T for 1978 to 2017. The size of the bubble is proportional to the number of fish in the catch by age and year. The values indicated at age 11 represent catches for ages 11 years and older.
Figure 6. Mean weight (kg) of Atlantic Herring for ages 4, 6, 8, and 10 of spring spawners (left panels) sampled from catches in the spring season and fall spawners (right panels) sampled from catches in the fall season from mobile (upper panels) and fixed (lower panels) commercial gears, in NAFO Div. 4T for 1978 to 2017.
Figure 7. Bubble plot of spring spawner Atlantic Herring fixed gear catch-per-unit-effort values (number per net-haul per trip) at age from NAFO Div. 4T for 1990 to 2017. The size of the bubble is proportional to the maximum CPUE index value.
Figure 8. Fixed gear age-disaggregated catch-per-unit-effort indices (number per net-haul per trip) of fall spawner (FS) Atlantic Herring by region (upper panel North, middle panel Middle, and lower panel South), from NAFO Div. 4T for 1986 to 2017. The size of the bubble is proportional to the maximum CPUE index value

Figure 9. Bubble plot of the fisheries-independent acoustic survey abundance-at-age indices (number of fish) for fall spawner (upper panel; ages 2 and 3) and spring spawner (lower panel; ages 4 to 8) Atlantic Herring for NAFO Div. 4T from 1994 to 2017.
Figure 10. Bubble plots of the experimental gillnet catch-at-age indices (numbers per hour) of fall spawner Atlantic Herring by region (upper panel North, middle panel Middle, and lower panel South) for NAFO Div. 4T from 2002 to 2017. The size of the bubble is proportional to the maximum CPUE index value79

Figure 11. Variations in the proportions of gillnets with mesh sizes $25 / 8$ inches used in the fall fixed gear fishery of AtlanticHherring by region for NAFO Div. 4T from 1986 to 2017. It is assumed that all other nets used were of mesh size $23 / 4$.

Figure 12. Multispecies bottom trawl survey abundance index (number of fish per standardized tow) for fall spawning Atlantic Herring of ages 4 to 6 years for NAFO Div. 4T from 1994 to 2017.

Figure 13. Residuals (observed - predicted indices) for population models of spring spawner Atlantic Herring in NAFO Div. 4T. The upper panel shows residuals for the CPUE index and the bottom panel shows residuals for the acoustic index. Rows are for ages and columns are for years. Circle radius is proportional to the absolute value of residuals. Black circles indicate negative residuals (i.e., observed < predicted) and white circles indicate positive residuals.81

Figure 14. Observed (circles) and predicted (lines and shading) age-aggregated CPUE (upper panels) and acoustic (lower panels) indices for the model of spring spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling.

Figure 15. Retrospective patterns in estimated spawning stock biomass (SSB, kt) of ages 5 to 10 for spring spawner Atlantic Herring in NAFO Div. 4T

Figure 16. Estimated fully-recruited catchability to the CPUE index for spring spawner Atlantic Herring for NAFO Div. 4T. Lines show the median estimates and shading their 95\% confidence interval based on MCMC sampling. 83

Figure 17. Fully-recruited catchability of Atlantic Herring to the spring gillnet fishery in relation to estimated spring spawner spawning stock biomass (SSB) for NAFO Div. 4T.

Figure 18. Estimated spawning stock biomass (SSB, kt) of the spring spawner component of Atlantic Herring in NAFO Div. 4T. Circles show the maximum likelihood estimates (MLEs). The solid line is the median MCMC estimate and shading its $95 \%$ confidence interval. The red dashed horizontal line is the Limit Reference Point (19,250 t of SSB). The blue dashed line shows the estimates from the 2016 assessment.

Figure 19. Recruitment rates for age 2 (circles) and age 4 (bars) recruits for the 1978 to 2013 cohorts of spring spawner Atlantic Herring in NAFO Div. 4T. Vertical lines indicate 95\% confidence intervals.

Figure 20. Estimated beginning-of-year abundance (millions) of 4 year old (blue bars) and 4 years and older (line) Atlantic Herring spring spawners in NAFO Div. 4T. Bars and the line show the median MCMC estimate and vertical lines or shading its $95 \%$ confidence interval. Age-4 abundance in 2018 (the red bar) was estimated assuming the recruitment rate for this cohort was the average of the rates for the preceding five cohorts.
Figure 21. Estimated exploitation rate of spring-spawning Atlantic Herring aged 6 to 8 years in NAFO Div. 4T. Circles are the median estimates based on MCMC sampling and vertical lines
their 95\% confidence intervals. The red horizontal line shows the reference level (F0.1 = 0.35) exploitation rate (0.295).
Figure 22. The population trajectory of the NAFO Div. 4T spring spawner Atlantic Herring expressed as the estimated spawning stock biomass (SSB) relative to the estimated fishing mortality rates for ages 6 to 8 years. The solid red vertical line is the Limit Reference Point (LRP; SSB = 19,250 t ), the green dashed vertical line is the Upper Stock Reference (USR; SSB $=54,000 \mathrm{t}$ ), and the orange dashed horizontal line is the removal rate reference ( $\mathrm{F} 0.1=0.35$ ) in the healthy zone when SSB > USR. Point labels are years ( $83=1983,0=2000$ ). Colour coding is from blue in the 1970s and early 1980s to red in the 2000s .87

Figure 23. Projected spawning stock biomass (SSB in kt) of spring spawner Atlantic Herring in NAFO Div. 4T for three recruitment scenarios (columns) and three catch levels (rows) in 2018 and 2019. Lines show the median estimates of the beginning-of-year SSB and shading the $95 \%$ confidence intervals of these estimates (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. The red horizontal line is the limit reference point (LRP).

Figure 24. Projected ages 6 to 8 fishing mortality rate (F) of spring spawner Atlantic Herring in NAFO Div. 4T for three recruitment scenarios (columns) and three catch levels (rows) in 2018 and 2019. Lines show the median estimates and shading their 95\% confidence intervals (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. The red horizontal line is the removal rate reference level (F0.1) corresponding to $\mathrm{F}=$ 0.35 .

Figure 25. Commercial gillnet CPUE index residuals (observed - predicted indices) by region (cpueN = North; cpueM = Middle; cpueS = South) and residuals between predicted and observed indices from the acoustic survey (Acoustic, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. Rows are for ages and columns are for years. The circle radius is proportional to the absolute value of the residuals. Black circles indicate negative residuals (i.e., observed < predicted) and white circles indicate positive residuals.
Figure 26. Experimental gillnet index residuals (observed - predicted indices) by region (exptIN = North; exptlM = Middle; exptIS = South), and residuals between predicted and observed indices from the RV survey (RV, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. Rows are for ages and columns are for years. The circle radius is proportional to the absolute value of residuals. Black circles indicate negative residuals (i.e., observed < predicted) and white circles indicate positive residuals.
Figure 27. Observed (circles) and predicted (lines and shading) age-aggregated commercial gillnet CPUE indices by region (CPUE North, CPUE Middle, CPUE South) and acoustic indices (Acoustic, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling.
Figure 28. Observed (circles) and predicted (lines and shading) age-aggregated experimental gillnet indices by region (North, Middle, South) and RV indices (RV, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling .91
Figure 29. Retrospective patterns in spawning stock biomass (SSB) of fall spawner Atlantic Herring within the three regions (North, Middle, South) and overall (Total) in NAFO Div. 4T..... 92

Figure 30. Estimated fully-recruited catchability of fall spawner Atlantic Herring for the commercial gillnet CPUE index by region (North, Middle, South) in NAFO Div. 4T. Lines show the median estimates and shading their 95\% confidence intervals based on MCMC sampling. 92
Figure 31. Estimated adjusted catchability (q) at age to the gillnet fishery in three regions (North, Middle and South) for fall spawner Atlantic Herring in NAFO Div. 4T. The adjusted catchability takes into account changes in mesh size and length at age as well as the changes over time in fully recruited $q$.

Figure 32. Catchability (q) at age to the experimental gillnets by region (upper left panel) compared to q-at-age in the commercial gillnet fishery in selected years (1986, upper right panel; 2000, lower left panel; and 2014, lower right panel) for fall spawner Atlantic Herring in NAFO Div. 4T

Figure 33. Fully-recruited catchability (q) in relation to spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring for the three regions in NAFO Div. 4T. For each region, the marker denotes the first year in the 1986 to 2017 time series.

Figure 34. Estimated spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring by region (North, Middle, South) and summed over regions (Total) in NAFO Div. 4T. The line and circles show the median estimates and the shading their $95 \%$ confidence intervals. In the lower right panel, the upper horizontal line is the upper stock reference level (USR) and the lower horizontal line is the limit reference point (LRP).

Figure 35. Posterior distributions of estimated total spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring in NAFO Div. 4T at the start of 2015 to 2018 based on MCMC sampling. In each panel, the dashed vertical line shows the Upper Stock Reference (USR = 172,000 ) and $p$ is the probability that the SSB will not be in the healthy zone (SSB $<U S R$ ). .

Figure 36. Estimated abundance (millions) of age 4 (histograms) and age 4+ (circle symbols and lines) fall spawner Atlantic Hrring in the three regions (North, Middle, South) and summed over regions (Total) of NAFO Div. 4T. Line and circles (age 4+) and bars (age 4) show the median estimates and shading or vertical lines show the 95\% confidence intervals

Figure 37. Estimated recruitment rate (recruits per kg of SSB) at age 2 (circles) and at age 4 (bars) of fall spawner Atlantic Herring in the three regions (North, Middle, South) and summed over regions (Total) of NAFO Div. 4T. Line and circles (age 4+) and bars (age 4) show the median estimates and shading or vertical lines show the $95 \%$ confidence intervals

Figure 38. Estimated ages 5 to 10 instantaneous fishing mortality rate ( $F$, left axes; annual exploitation rate right axes) of fall spawner Atlantic Herring in the three regions (North, Middle, South) and averaged over regions (Total; weighted by regional abundance at ages 5-10 years) in NAFO Div. 4T. Lines show the median estimates and shading their $95 \%$ confidence intervals. In the lower right panel, the horizontal line shows the reference removal rate ( $F 0.1 ; F=0.32$ ) that applies in the healthy zone
Figure 39. Population trajectory of the fall spawner component of Atlantic Herring in NAFO Div. 4T expressed as the spawning stock biomass (SSB) relative to the fishing mortality rates for ages 6 to 8 years. The solid red vertical line is the LRP $(58,000 \mathrm{t})$, the green dashed vertical line is the Upper Stock Reference ( $\mathrm{USR}=172,000 \mathrm{t}$ ), and the orange dashed horizontal line is the removal rate reference ( $\mathrm{FO} 1 ; \mathrm{F}=0.32$ ). Point labels are years $(83=1983,0=2000)$. Colour coding is from blue in the 1970s and early 1980s to red in the 2000s.
Figure 40. Estimated and projected spawning stock biomass (SSB in kt; left column) and ages 5 to 10 fishing mortality rate (F) (right column) of fall spawner Atlantic Herring in NAFO Div. 4T for three annual catch levels (rows) in 2018 and 2019. Lines show the median estimates of the
beginning-of-year SSB or the median estimates of $F$ in the year whereas shading shows the $95 \%$ confidence intervals of these estimates (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. In the left column, the blue horizontal dashed line is the upper stock reference (USR) and the red horizontal line is the limit reference point (LRP). In the right column, the red horizontal line is the removal rate reference level (F0.1; F = 0.32) .100

Figure 41. Profiles of the estimated probabilities of the projected spawning stock biomass (SSB) of fall-spawning Atlantic Herring at the start of 2019 and 2020 relative to stock status indicators for increasing levels of annual catch from 10,000 $t$ to $50,000 \mathrm{t}$ in 2018 and 2019. The stock status indicators are: a) the probability that SSB will be less than the USR at the start of 2019 (dashed line) and 2020 (solid line) (top left panel); b) the probability that SSB will be below the 2018 level (top right panel); c) the probability of a 5\% increase above the 2018 level (lower left panel); d) the probability of a $5 \%$ decrease below the 2018 level (lower right panel). 101

Lawrence.

#### Abstract

Atlantic Herring (Clupea harengus) in NAFO Division 4T, referred to as the southern Gulf of St. Lawrence (sGSL), consists of two spawning components, spring spawners (SS) and fall spawners (FS). This document presents the most recent information on trends in abundance, distribution, and harvest for the SS and FS herring components. This includes catch-at-age and catch-per-unit-effort (CPUE) indices, fisheries-independent acoustic indices, catch rate index from the experimental gillnet survey, mesh selectivity, and catches in the multi-species bottom trawl survey of the sGSL. The data and indices are reported for the sGSL for the SS and regionally-disaggregated (North, Middle, and South regions) and overall for the FS where applicable.

SS were assessed using a virtual population analysis (VPA) which allowed for time-varying catchability to the gillnet fishery. The model estimated that SS spawning stock biomass (SSB) has been in the critical zone of the Precautionary Approach (PA) framework since 2004. The median SSB at the start of 2018 is estimated to be approximately $12,000 \mathrm{t}, 65 \%$ of the limit reference point ( $\mathrm{LRP}=19,250 \mathrm{t}$ ). The instantaneous rate of fishing mortality ( $F$ ) on aged 6 to 8 year old SS herring exceeded the removal reference level ( $F 0.1 ; F=0.35$ ) until 2012. Under various recruitment scenarios (low, mixed, or high recruitment), SSB is expected to decrease at any catch options over 500 t for the next two years. By 2027, the probability of exceeding the LRP was most favorable under the high recruitment scenarios and low catches ( $<1,500 \mathrm{t}$ ), however under the low recruitment scenarios even with no catch there was only a $13 \%$ probability of SSB exceeding the LRP. FS were assessed as regionally-disaggregated populations using a VPA which allowed for timevarying catchability to the gillnet fishery. Estimated SSB has been declining in all three regions in recent years, though it increased in the South over the last two years. Summed over all three regions, SSB at the start of 2018 is estimated to be approximately $112,000 \mathrm{t}$ with a $97 \%$ probability of being within the cautious zone of the PA framework (SSB is below the upper stock reference (USR $=172,000 \mathrm{t})$ ). Averaged over all regions, F of aged 5 to 10 exceeded F0.1 ( $F=0.32$ ) from 1994 to 2011, but remained below since 2012. The median projected value of SSB at the start of 2020 remained below the USR at all catch levels between 10,000 and $50,000 \mathrm{t}$, with the probability of being below the USR varying from $90 \%$ at $10,000 \mathrm{t}$ to $99 \%$ at $50,000 \mathrm{t}$. The probability that F of aged 5 to 10 FS will exceed F 0.1 in 2019 is estimated to increase from $0 \%$ at catches of $10,000 \mathrm{t}$ to $99.6 \%$ at $50,000 \mathrm{t}$.

## 1. INTRODUCTION

Atlantic Herring (Cupea harengus) in the southern Gulf of St. Lawrence (sGSL) are found in the area extending from the north shore of the Gaspe Peninsula to the northern tip of Cape Breton Island, including the Magdalen Islands, encompassing the Northwest Atlantic Fisheries Organization (NAFO) Division 4T. Adults overwinter off the north and east coast of Cape Breton in the NAFO divisions 4T and 4Vn (Claytor 2001; Simon and Stobo 1983; Fig. 1). Studies in the early 1970s indicated that sGSL herring also overwintered off the south coast of Newfoundland, but an exploratory fishery in 2006 did not detect any concentrations (Wheeler et al. 2006). Herring in the sGSL are managed across seven herring fishing areas (HFA) in area 16 (A-G; Fig. 1a). These herring fishing areas cover the same region as NAFO Div. 4T (Fig. 1).

Atlantic Herring is a pelagic species that schools particularly during feeding, spawning periods, and annual migrations. First spawning typically occurs at age four. Eggs are attached to the sea floor and large females can produce up to 360,000 eggs (Messieh 1988).

The herring population in the sGSL consists of two spawning components, spring spawners (SS) and fall spawners (FS). Spring spawning occurs primarily in April-May but extends to June 30 at depths $<10 \mathrm{~m}$. Fall spawning occurs from mid-August to mid-October at depths of 5 to 20 m , but can occur as early as July 1. The SS and FS herring of NAFO Div. 4T are considered distinct stocks which are assessed separately. Recent genetic studies have confirmed genetic differentiation among these stocks (Lamichhaney et al. 2017). Herring also show high spawning site fidelity (Wheeler and Winters 1984; McQuinn 1997; Brophy et al. 2006) and local stocks are targeted by the gillnet fishery which takes place on the spawning grounds. FS herring in sGSL are therefore assessed using regionally-disaggregated assessment models (North, Middle, South regions; Fig. 1b).
The sGSL herring are harvested by a gillnet fleet (referred to as "fixed" gear fleet) and a purse seine fleet ("mobile" gear fleet). The mobile gear fleet consists of five large southern Gulf vessels (> 19.8m). Nonetheless, some "small seiners" (<19.8m) can also participate in the inshore fishery as part of the gillnet fleet. The fixed gear fishery is focused in NAFO Div. 4T, whereas the mobile gear fishery occurs in NAFO Div. 4T and occasionally in Div. 4Vn (Fig. 1). During the spring and fall fishing seasons, the mobile fleet are prohibited from fishing in areas set aside exclusively for the fixed gear fleet (Claytor et al. 1998). In the spring fishery, mobile gear fleets fish along the northern boundary of NAFO region 4Tf, this is referred to as the "Edge" fishery. Both SS and FS herring are harvested in the spring and fall fisheries and must therefore be separated into the appropriate groups.
Prior to 1967, sGSL herring were mainly exploited by fixed gear and average landings during 1935 to 1966 were $34,000 \mathrm{t}$. In the mid-1960s, a mobile gear fishery was introduced and average landings by both fleets were $166,000 \mathrm{t}$ for the period 1967 to 1972 . Since 1981, the fixed gear fleet has accounted for most of the catch of SS and FS herring (McDermid et al. 2015).

A global allocation or Total Allowable Catch (TAC) was first introduced in 1972 at 166,000 t, and reduced to $40,000 \mathrm{t}$ in 1973. Separate TACs for the SS and FS components began in 1985. The TACs were first allotted by fishing season and later attributed to SS or FS landings based on biological samples taken during the fishery. The percentage of SS and FS in the catch varies according to season and gear type. As a result, landings during the spring and fall fisheries must be separated into the appropriate SS and FS groups to determine if the Total Allowable Catch (TAC) for these groups has been attained.

The population modelling is conducted for the assessment SS and FS herring to the end of 2017 (or to Jan. 1 of 2018), with projections for Jan. 1 of 2019, 2020, and 2027.

## 2. DATA SOURCES

For the SS herring, a single NAFO Div. 4T model is used.
For the FS herring, a regionally-disaggregated model for three regions (North, Middle, South) that encompass the entire NAFO Div. 4T area is used. The regions are defined on the basis of traditional herring spawning beds and fishing areas (Fig. 1):

- North (Gaspé and Miscou; 4Tmnopq),
- Middle (Escuminac-Richibucto and west Prince Edward Island; 4TkI), and
- South (east Prince Edward Island and Pictou; 4Tfghj).

The choice of three regions was dictated by geographic proximity of spawning beds and is the finest level of disaggregation that can presently be supported by the available data. The regionally-disaggregated models include inputs that are region-specific (e.g., catch-at-age, catch-per-unit-effort) and inputs that are common to the entire area (e.g., acoustic survey index, size-at-age).
When calculating region-specific catches-at-age, catches made by herring seiners during the fall fishery were attributed to the region in which they were made, whereas catches made during the late spring and summer were attributed to the South region, which is most proximate to the location of capture. Catches made in NAFO Div. 4Vn during a winter fishery that took place prior to 1999 were attributed to the regional catches in proportion to those regional catches.

### 2.1 LANDINGS

Catch data were taken from purchase slips and ZIFF (zonal interchange file format) files collected by the Statistics Branch of Fisheries and Oceans Canada (DFO). Catch data to 1985 are available by fishery (fixed and mobile) and by fishing area. Beginning in 1986, the catch data are further reported by vessel and trip. The ZIFF files are based on information collected by the Dockside Monitoring Program (DMP). This program provides accurate, timely, and independent third-party verification of fish landings. Contracted companies are hired by the fishing industry to observe the offloading of fish and to record and report the landings information to DFO.
The fishery TACs are set for the sGSL SS and FS components, separately. In 2016 and 2017, the TACs were set at 2,000 t for the SS and $35,000 \mathrm{t}$ for the FS, for a total of $37,000 \mathrm{t}$ (Table 1; Fig. 2). Seventy-seven percent of the TAC for each spawning component was allocated to the fixed gear fleet with the remaining $23 \%$ for the mobile gear fleet (Table 1).
The preliminary estimated landings of SS herring in both the spring and fall fisheries were 966 t and 1,189 t for 2016 and 2017 respectively (Table 1; Fig. 3). The 2016 and 2017 TAC was $2,000 \mathrm{t}$. Most of the SS herring were estimated to have been landed in the fixed gear fleet over the 1981 to 2017 period. In 2016 and 2017, the fixed gear fleet was estimated to have landed $82 \%$ and $96 \%$, respectively, of the total harvests of SS herring (Table 1; Fig. 3). More than 80\% of the SS herring landed by the fixed gear fleet is landed during the spring fishing season, whereas most (> $80 \%$ ) of the SS herring landed by the mobile fleet is landed in the fall season (Fig. 3).

The preliminary landings of $F S$ in 2016 and 2017 were $24,677 t$ and 20,523 $t$ respectively (Table 1; Fig. 3). The 2016 and 2017 TACs were 35,000 t. Over the 1978 to 2017 period, most
of the FS herring have been landed in the fixed gear fleet. In 2016 and 2017, the fixed gear fleet was estimated to have landed $94 \%$ and $99 \%$, respectively, of the total harvests of FS herring (Fig. 3). The majority (nearly 100\%) of the FS herring captured in the fixed gear fishery are landed during the fall fishing season. The mobile fleet has landed varying amounts of FS herring in the fall, 31\% to 45\% during 2016 and 2017 (Fig. 3).

During 2010 to 2017, the mean proportion of the total catch caught by fixed gear was $63 \%$ for the SS and $93 \%$ for the FS (Table 1). The majority of the 2016 and 2017 FS fixed gear catches occurred in herring fishing areas 4Th (South) and 4Tmn (North; Table 2). Meanwhile, the majority of the 2016 and 2017 fixed gear catches during the fall season occurred in herring fishing area 4Tmn (North; Fig. 1; Table 2). The mobile gear (Edge) spring season fishery landed $1,120 t$ and $90 t$ in 2016 and 2017 respectively. The fall season mobile gear catches in 2016 and 2017, 771 t and 816 t , respectively, were all from herring fishing area 4Tmn (North region; Fig. 1; Table 2).
In 2016, 48\% of the SS TAC was attained compared to $59 \%$ in 2017. In 2016, 71\% of the FS TAC was attained compared to $59 \%$ in 2017. Herring fishing area percentages of TAC attained are found in Table 2.

Management measures were introduced in 2010 to improve the status of SS component. These measures include:

- fishing closure on some spawning areas in all HFA except 16A and 16F,
- weekly landing limits of $10,206 \mathrm{~kg}$ in all HFA except $16 \mathrm{~A}, 16 \mathrm{D}$, and 16 F , where no restrictions will apply, and
- no nets or herring allowed on board during a fishing trip between 18:00 and 04:00 (ADT) in fishing area 16C-G and between 22:00 and 03:00 (ADT) in fishing areas 16A and 16B.

### 2.1.1 Spawning stock assignment

Three methods are used to assign herring samples to either SS or FS based on gonad maturity stages (Cleary et al. 1982):

1. For immature herring of maturity stages 1 and 2 (juveniles), the season of hatching is based on the size at capture and a visual examination of otolith characteristics (Messieh 1972). The spawning component assignment for juvenile herring is its hatching season (Cleary et al. 1982). Juveniles represent a small percentage of commercial catch, but are a higher proportion in the research survey samples.
2. Adult herring with ripe or spent gonads are assigned their maturity stage by macroscopic laboratory examination of the gonads. The fish are assumed to belong to the spawning component of the season in which they were caught. These represent over $90 \%$ of the fixed gear catches and $75 \%$ of the total annual landings.
3. Adult herring with unripe gonads are assigned their maturity stage by using a gonadosomatic index (GSI) based on a discriminant function model. The GSI is based on the length of the fish and its gonad weight (McQuinn 1989). Once the maturity stage is determined by GSI, the spawning component is assigned by using a maturity schedule decision rule (a table cross-referencing maturity stage assigned by GSI and the date of capture to assign a spawning component) (Cleary et al. 1982).

For the month of June, the GSI and macroscopic examination methods resulted in different assignment of samples to spawning components. In particular, the 2012 and 2013 Cabot Strait Edge fishery samples were not well classified by the GSI method. The macroscopic examination
identified at least $95 \%$ of the gonads as developing gonads therefore classifying them as FS. The GSI discriminant function reclassified at least $20 \%$ of these developing gonads as spent gonads resulting in a classification of SS. A change was made to the decision rules for the GSI method such that a "spent" gonad in June is classified as a FS.

### 2.2 TELEPHONE SURVEY

A telephone survey has been conducted annually since 1986 to collect information on the fixed gear fishery and opinions on abundance trends of Atlantic Herring in the sGSL (details in LeBlanc and LeBlanc 1996). The sGSL was divided into eight telephone survey areas corresponding to the areas where the major fisheries occur (Fig. 1c). A subset of active commercial licence holders was asked a series of questions concerning the number, dimensions, and mesh size of nets used, the frequency of fishing, how the abundance in the current year compared to the previous year, and the medium-term trend. A 2008 review of the consistency of the abundance relationship among years concluded that this index should not be used as an aggregated biomass index in the population model. The telephone survey responses provide information on fishing effort related to the number of nets, mesh size, and fishing frequency.

The 2016 fixed gear telephone survey contacted 194 fishermen randomly selected out of approximately 553 active commercial licence holders in both seasons combined. Thirty-five fishermen from the spring fishery and 126 fishermen from the fall fishery responded, for a total of 161 respondents. The 2017 fixed gear telephone survey contacted 170 fishermen randomly selected out of approximately 513 active commercial licence holders in both seasons combined. Thirty-nine fishermen from the spring fishery and 100 fishermen from the fall fishery responded, for a total of 139 respondents. The distribution of respondents across the eight telephone survey areas in terms of mean net hauls, net lengths, and trend in the abundance from the previous year are summarized in Table 3. Overall, fishermen felt that abundances in the 2017 spring fishery season were similar to those of 2016 and to those in the previous assessment. For the fall fishery, there was a sense that the 2017 abundance in the North and Middle regions had declined slightly when compared to 2016 and the previous assessment whereas the abundance of herring in the South region had continued to decline since 2015 (Table 3).
The gillnet fishery data used for the abundance index were those with the greatest number of records in a given year (Table 3). In the spring fishery, mesh sizes of gillnets have been relatively constant at $21 / 2^{\prime \prime}$. In the fall fishery, $25 / 8^{\prime \prime}$ mesh is the most common; however in 1992 many fishers started using bigger mesh sizes ( $23 / 4$ "). By 2002, the proportion of $25 / 8^{\prime \prime}$ mesh reverted to pre-1992 numbers. The proportion of $25 / 8^{\prime \prime}$ mesh in 2016 and 2017 was $100 \%$ (Table 3).

### 2.3 FISHERY SAMPLING

Commercial fishery catches are sampled dockside by DFO scientific personnel for the fixed and mobile fisheries, and at sea by fisheries observers in the mobile fishery. Sampling procedures are designed to obtain samples that are spatially and temporally representative of landings. The landings and samples by area used to calculate catch-at-age are shown in Table 2. The samples are used to determine the size, age, and spawning component (SS or FS) composition of the catch. Yearly age reading consistency tests are done in order to evaluate and ensure the consistency of age reading over time (Appendix A).

### 2.4 FISHERY-INDEPENDENT ACOUSTIC SURVEY

Since 1991, an annual fishery-independent acoustic survey of early fall (September-October) concentrations of herring in the southern Gulf has been conducted. The standard annual survey area occurs in the NAFO 4Tmno areas where sGSL herring aggregate in the fall. In some years, the acoustic survey also covered waters north of P.E.I. The survey uses a random stratified design of parallel transects within predefined strata. Surveys are conducted at night with two vessels: an acoustic vessel to quantify the biomass of fish schools using a hull-mounted 120 KHz single beam transducer, and a fishing vessel to sample aggregates of fish with a pelagic trawl (LeBlanc and Dale 1996; LeBlanc et al. 2015). The acoustic survey covered a total transect distance of 702 km in 2016 and 885 km in 2017 within the NAFO 4Tmno areas (Appendix Figure B1). Appendix Figure B1 shows the distribution of estimated herring schools during the 2015 to 2017 survey. Biological samples are used to separate the observed biomass into spawning components and ages, determine species composition, and size distribution for the estimation of the target strength (LeBlanc and Dale 1996; LeBlanc et al. 2015).

The 2015, 2016, and 2017 acoustic biomass indices of the NAFO 4Tmno areas for SS and FS herring combined were $157,373 \mathrm{t}, 63,493 \mathrm{t}$, and $69,023 \mathrm{t}$, respectively. The biomass was composed of $19 \%$ SS and $81 \%$ FS on average over the three years. A complete summary of the acoustic survey results is available in Appendix B.

### 2.5 EXPERIMENTAL NETS

In this industry partnership project between DFO and the provincial fishery associations, experimental gillnets, consisting of multiple panels of varying mesh size, were deployed approximately weekly by fixed gear fishermen during the fall herring fishery. These modified gillnets catch a wider range of fish sizes than the commercial gear and provide information on the relative selectivity of various mesh sizes. Catches from the experimental nets project have been used to estimate the relative size-selectivity of gillnets of different mesh sizes and to produce age-disaggregated abundance indices (Surette et al. 2016a). Both are inputs to the FS assessment model.

Each experimental gillnet had five panels of different mesh sizes, from a set of seven possible mesh sizes, ranging from 2 " to $23 / 4^{\prime \prime}$ in $1 / 8^{\prime \prime}$ increments. All gillnets had panels with mesh sizes of $21 /{ }^{\prime \prime}, 25 / 8^{\prime \prime}$, and $23 / 4^{\prime \prime}$, plus two smaller mesh sizes that varied among fishermen. Harvesters in the fall fishery fishing on the Miscou Bank (North region; 16B), Gaspé (North; 16B), Escuminac (Middle; 16C), West PEI (Middle; 16E), Fisherman's Bank (South; 16G), and Pictou (South; 16F) spawning grounds participated in the study (Fig. 1a). The target fishing procedure was a one hour soak and nets were set during the commercial fishery activities on the fishing grounds. Data from Pictou prior to 2015 were corrected for gillnet depth as nets in this region were 5 m ( 17 feet) deep compared with the standard 2.4 m ( 8 feet) used on other spawning grounds. A correction factor of $8 / 17$ (in feet) was applied to the Pictou nets to address the difference in net depth size.

### 2.6 SPAWNING GROUND ACOUSTIC SURVEYS

In 2015, a spawning ground acoustic survey project was initiated that follows the design of the fishery-independent acoustic survey (Section 2.4). The survey design uses random parallel transects within predefined strata that cover the same spawning grounds as the experimental nets (Section 2.5; Appendix C). The survey is an industry partnership between DFO and the provincial fishery associations. Surveys are conducted by fishermen according to protocols developed by DFO. The survey is conducted at night during the fall fishery weekend fishery closures except in herring fishing areas 16C and 16E (Middle; Fig. 1a). The Middle region does
not have weekend closures, therefore the survey can only be conducted pre- and post-season. The spawning ground acoustic survey is intended to provide a nightly estimate of spawning biomass among regions. It is analyzed in the same manner as the acoustic survey (Section 2.4). The catches from the experimental nets (Section 2.5) are used to calibrate the target strength for the acoustics in order to obtain the nightly estimates of spawning biomass.

This pilot project has not been incorporated into the assessment models. The results of the first three years of data are summarized in Appendix C. The results highlight the importance of following protocol and weekly surveys in assessing local relative abundances. While the results are not used in this assessment, the goal is to include these results in later assessments when annual and consistent data are available.

### 2.7 MULTISPECIES BOTTOM-TRAWL SURVEY

The annual multi-species bottom trawl survey, conducted each September since 1971, provides information on the abundance and distribution of NAFO 4T herring throughout the sGSL in September (Hurlbut and Clay 1990; Savoie 2014). Total catch weights and numbers, a representative length frequency, and representative individual length-weight data have been recorded for each fish species in each survey set since 1971. Since 1994, additional sampling of herring catches has been undertaken to disaggregate catches by spawner group and age. Herring were primarily caught near shore in waters < 30 fathoms, mostly off northeast P.E.I., west of Cape Breton, as well as in the Northumberland Strait, and Chaleur Bay (Appendix Figure D1). The number and weight of the 19 to 26 cm length group of herring per tow decreased in 2016 with a slight increase in 2017. This size-class represents the herring not recruited to the fishery and of ages 2 to 3 (Appendix Figure D2). The numbers and weights of herring large enough to be captured in the fall fishery (> 26 cm ) decreased from 2016 to 2017.

## 3. INPUTS AND INDICES

### 3.1 CATCH-AT-AGE AND WEIGHT-AT-AGE MATRICES

Catch-at-age and weight-at-age matrices for sGSL herring SS and FS components are derived for each of the fixed and mobile gear fleet catches. These were calculated using age-length keys and length-weight relationships for each spawning component, gear type, and fishing season (Table 2). When fewer than 30 fish were sampled for detailed analysis, the overall length-weight relationship and age-length key most similar and adjacent in gear, geography, and time were used to estimate the catch-at-age. Catch-at-age and weight-at-age by spawning component are presented for the fixed gear (for SS, Tables 4 and 5; for FS Tables 6 and 7) and the mobile gear (for SS, Tables 8 and 9 ; for FS, Tables 10 and 11) fishery catches. Regionspecific catch-at-age and weight-at-age are reported for the fall spawner fixed gear catches (Tables 6 and 7).

The dominant age in the 2016 SS catch was age 7, belonging to the 2009 year-class. In 2017 it was age 5, belonging to the 2012 year-class (Tables 4 and 8; Fig. 4). For FS, the dominant age in 2016 and 2017 was 6 and 7 years, respectively (Tables 6 and 10; Fig. 5), thus the 2010 yearclass.

Beginning of year weights-at-age are calculated from the weights-at-age for fixed and mobile gears combined. It is calculated from the average of the weight-at-age and the weight-at-age for the following age-class. The 2017 beginning of year weights-at-age were averaged from the 2014 to 2017 commercial weights adjusted to the beginning of the year. Mean weights-at-age of the SS caught in the mobile and fixed gears in the spring season have declined since the 1990s for mobile gear, and since the mid-1980s for the fixed gear (Tables 5 and 8; Fig. 6). Mean
weights-at-age of FS herring from fixed and mobile gears have declined almost continuously over the time period 1978 to present (Tables 7 and 11; Fig. 6). Lower mean weights are an indication of the status of the stock (fish are becoming smaller at age) and affect the stock biomass estimate when numbers are converted to weight.

### 3.2 CATCH-PER-UNIT EFFORT

The fixed gear fisheries occur on the spawning grounds and landings from this fishery account for approximately $60 \%$ of the SS and more than $90 \%$ of the FS catch. Fixed gear catch and effort data were used to construct age-disaggregated abundance indices for SS and FS NAFO 4T herring, based on catch-per-unit-effort (CPUE). The fixed gear CPUE indices are defined as catches in kg/net-haul/day (or kg/net-haul/trip). Age-specific CPUE indices for ages 4 to 10 are used in the assessments for the stock.

Catch data were taken from the landings data. Fishing effort was calculated as the average number of gillnets deployed by season and area for the sGSL since 1978. From 1978 to 1985, the average number of nets used was collected by questionnaires done on wharves and by mail (Clay and Chouinard 1986). Since 1986, the fishing effort was calculated as the number of trips (purchase slips) multiplied by the estimated number of standard net hauls, which were determined from the DMP records and the annual telephone survey depending on which has the most data (Table 3). Fall fishery data on the number of nets set are available since 1978 and the number of hauls since 1986. Fall fishery catch and effort DMP records are available since 1990. Nets are standardized to a length of 14 fathoms ( 25.6 m ).
The percent of fixed gear fishing days with no catch has been recorded since 2006 based on responses during the telephone survey (Table 12). The percentage of days with no catch in the spring fishery of 2017 is slightly higher than average, while the percentage of days in the fall is among the highest in the time series. Since this information is available only for the most recent period, it is not presently included in the calculation of fishing effort.
A multiplicative model (GLM) is used to calculate the standardized indices, based on the following formulation:

$$
\begin{equation*}
\ln \left(\text { CPUE }_{\mathrm{ijk}}\right)=\alpha+\beta_{1} \mathrm{I}+\beta_{2} J+\beta_{3} \mathrm{~K}+\epsilon \tag{1}
\end{equation*}
$$

where $\mathrm{i}(\mathrm{I})$ indexes year, $\mathrm{j}(\mathrm{J})$ indexes telephone survey area, $\mathrm{k}(\mathrm{K})$ indexes week, $\alpha$ is the intercept, $\beta$ is the slope, and $\epsilon$ is the residual error. For the SS, the model was applied to the data for the whole stock area. For the FS, GLMs were run by region (North, Middle, and South) and did not include the area term. The SS analysis was limited to weeks 9 to 22 whereas the FS analysis was restricted to weeks 27 to 43.
The models explained over $40 \%$ of the variance in the data and the factors for year, week, and area were statistically significant (Table 13). Age-specific CPUE indices for ages 4 to 10 are used in the assessments for the SS and FS components. The age-specific abundance indices for ages 4 to 10 were derived by dividing the gillnet catch-at-age by the standardized effort (CPUE) from the multiplicative GLM model. The CPUE age-specific abundance indices include the years 1986 to 2017. The indices presented in Tables 14 and 15 and Figures 7 and 8 account only for catch and effort, and do not account for possible changes in selectivity / catchability, which are addressed as part of the population modelling. The CPUE index for SS and FS shows internal consistency as the abundance of cohorts is correlated between years (Figs. 7 and 8). The overall SS CPUE was higher in 2017 than in 2016 (Table 14). The CPUE of SS increased in 2017 across all ages except age 10 (Table 14; Fig. 7). The CPUE of FS declined in 2017 for both the North and Middle regions but increased in the South from the low
levels observed in 2016 (Table 15; Fig. 8). Across regions, the CPUE of FS younger fish (ages 4 and 5) has remained low since 2009 (Fig. 8).
Fixed gear catches of SS in 2016 and 2017 were composed mostly of ages 6 to 8 (Table 4; Fig. 4). In the North and Middle regions, catches of FS in 2016 were dominated by ages 6 and 7 and in 2017 by ages 7 and 8 (2009 and 2010 year-classes). In the South region, catches of FS in 2016 and 2017 were dominated by ages 7 and 8 respectively (2009 year-class; Table 6; Fig. 5).

### 3.3 FISHERY-INDEPENDENT ACOUSTIC SURVEY INDEX

A second standardized abundance index is generated from the annual fishery-independent acoustic survey. This index includes catch-at age data from NAFO areas 4Tmno which have been surveyed yearly since 1994. The age-disaggregated acoustic abundance indices for ages 2 to 10 for SS and FS are presented in Table 16.

The SS assessment model uses the age-disaggregated abundances for ages 4 to 8 (Table 16). The acoustic survey estimated that catch rates (in numbers) of SS of ages 4 to 8 were greater in 2015 and 2017 than in 2014 and 2016, however all values were consistent with the low abundances estimated since the early 2000s (Fig. 7). The acoustic survey catches of the SS in 2015, 2016, and 2017 were dominated by the 2013 year-class (ages 2, 3, and 4, respectively). In 2015, the abundance of age 2 (2013 year-class) also dominated the SS abundance (Table 16; Fig. 7).

For the FS assessment model, the acoustic survey provides a useful abundance index of recruiting herring (ages 2 and 3; LeBlanc et al. 2015). It is not thought to provide a useful abundance index for older ages given that the survey is limited to a restricted portion of the sGSL at a time when older herring are in areas throughout the sGSL spawning. The 2012 yearclass dominated the FS abundances in 2015, 2016, and 2017 (ages 3, 4, and 5 respectively; Table 16). The acoustic abundance of age 2 and 3 FS in 2015 was over six times greater than in 2016 and 2017. The abundances in 2016 and 2017 returned to the lower levels of the time series (Table 16; Fig. 9).

### 3.4 EXPERIMENTAL NET INDICES

### 3.4.1 Catch-at-age of experimental nets

Region-specific age-disaggregated abundance indices are generated for the FS assessment from standardized experimental net data (Table 17). This index includes catch-at-age based on a one hour soak time. The experimental net index suggests an increase in young herring (ages 2 to 4) until 2009, after which the numbers decline. No major trend was observed in older herring over the time series (Table 17; Fig. 10). The index shows an increased abundance of herring in the North, no strong trend in the Middle region, and an overall decline in the South region, particularly at younger ages (Fig. 10).

### 3.4.2 Relative selectivity index

A relative selectivity index was developed to correct for changes in the proportion of $25 / 3$ ", and $23 / 4$ " meshes used by commercial fishermen, as well as changes in mean length-at-age which have generally decreased over time. Annual age-length keys were first derived from age samples collected from the commercial gillnet fishery from 1986 to 2017 and the experimental gillnet study from 2002 to 2017 during the months of August to October. Annual catch-at-length estimates for the commercial gillnet fishery from 1986 to 2017 were then calculated using length frequency samples gathered over the same months. The age-length keys and catch-at-length estimates were combined to yield catch-at-lengths by age and year. At this point, two selectivity-
at-length curves, estimated from the gillnet selectivity study and assumed constant over time, were applied to these catch-at-lengths, one corresponding to the $25 /{ }^{\prime \prime}$ mesh size and the other to the $23 / 4$ " mesh size. Summing over lengths yields annual catch-at-age estimates for the commercial fishery by mesh size. The ratio of the mesh size adjusted catch-at-ages to the fishery catch-at-age yields selectivity-at-age proportions by mesh size and year. These selectivity-at-age proportions (Table 18; Fig. 11) were then applied to catch-at-age CPUEs for the $25 /{ }^{\prime \prime}$ and $23 /{ }^{\prime \prime}$ " mesh sizes. A weighted sum of these two CPUEs using the proportion of fishery catches from each of the two mesh sizes yielded an adjusted CPUE catch-at-age for the fall fishery.

### 3.5 MULTISPECIES BOTTOM TRAWL INDEX

Catches of herring in the multispecies bottom-trawl survey can be quite variable, even within areas where herring are common (e.g., see Savoie 2014). This index consisted of an agedisaggregated index using data from 1994 to 2017 for the FS only (Table 19; Fig. 12). Catch-atage (mean number per standardized tow) of FS herring in the multispecies trawl survey was estimated using a Bayesian estimation model (Surette et al. 2016b). The index suggests an increasing trend in four year old FS herring from the mid-1990s to 2011, and generally higher abundance of six year old FS herring in the 2000s compared to the 1990s (Fig. 12).

### 3.6 MATURITY OGIVE

For the purposes of the assessment, herring are assumed to follow a knife-edged maturity schedule, with $100 \%$ maturation occurring between the ages of 3 and 4 .

## 4. SPRING SPAWNER COMPONENT ASSESSMENT

The assessment of SS uses a virtual population analysis (VPA) fit to two indices of abundance at age; fishery catch rates at ages 4 to 10 years (the CPUE index), and abundance indices at ages 4 to 8 years based on a fall acoustic survey. Prior to the 2016 assessment (which used data to the end of 2015), the fit of the VPA model to the CPUE index was poor, with severe residual patterns between the observed indices and the model predictions. The model also displayed a strong "retrospective pattern", with estimates of spawning stock biomass (SSB) in a given year progressively declining as additional years of data were added to the analysis. These results suggested that the model failed to incorporate one or more non-stationary processes in the population dynamics of this stock or in the observation model relating indices of abundance to population abundance. The 2016 assessment examined two possible non-stationarity factors: time-varying natural mortality $(M)$ and time-varying catchability $(q)$ to the fixed gear fishery (and thus to the CPUE index). Allowing $q$ to vary over time resolved these problems but time-varying $M$ did not (Swain 2016a). Fishery dependent indices are an important component of the assessment. Indices such as the commercial gillnet CPUE, may not be proportional to abundance due to changes in catchability over time. For example, catch rates can remain elevated despite decreases in abundance (increased catchability) due to contractions in stock distribution and targeting of aggregations by fishing fleets, as well as due to improved fishing technology and fishing practices.

This assessment uses the same model as the 2016 assessment, with catchability to the springspawning herring fishery allowed to vary over time.

### 4.1 SPRING SPAWNER MODEL

The SS component is assessed using a virtual population analysis (VPA) model implemented using AD Model Builder (Fournier et al. 2011). The SS model incorporated ages 2 to 11+ (i.e.,

11 years and older) and began in 1978. Abundance of the plus group (11+) was estimated using the F-ratio method (Gavaris 1999). M was assumed to be constant at 0.2 for all years and ages. Data inputs to the model included:

- fishery catches at ages 2 to 11+ (in numbers) (Tables 4 and 8),
- catch-per-unit-effort (CPUE) index from 1990 to 2017 (ages 4 to 10 years) (Table 14),
- fishery-independent acoustic survey index from 1994-2017 (ages 4 to 8) (Table 16).

Model parameters included abundance at ages 5 to 11+ at the beginning of 2018, q at age to the fishery (i.e., the CPUE index, ages 4-10) and to the acoustic survey (ages 4-8), and the standard deviation (SD) of observation error at age for each of the indices. All parameters were estimated on the log scale.

The model allowed for process error in fully-recruited catchability (q) to the fixed gear fishery. Catchability to the fishery was estimated for 1990 to 2017 (the years with CPUE data) and was modelled as selectivity at age times fully recruited q (Swain 2016a). Selectivity was modelled as a logistic function of age for ages 4 to 9 , but was freely estimated for age 10 to allow for domeshaped selectivity at age. Fully-recruited q was freely estimated for 1990 and then allowed to vary over time following a random walk:

$$
\begin{equation*}
q_{1990}=q_{\text {init }} \text { and } q_{t}=q_{t-1} e^{q d e v_{t}} \text { where } \mathrm{t}>1990 . \tag{2}
\end{equation*}
$$

The $q$ deviations were assumed to be normally distributed with a mean of 0 and a standard deviation of 0.1. The objective function for the model included a term penalizing departures of the $q$ deviations from 0 .
Model estimates and their uncertainty were evaluated based on MCMC sampling, with every $500^{\text {th }}$ of $2,500,000$ samples saved. Because the youngest age in the abundance indices is age 4 , it is not possible for this model to obtain direct estimates of abundance at ages 2 to 4 at the beginning of 2018, ages 2 to 3 at the beginning of 2017 , and age 2 at the beginning of 2016 . These were obtained using the estimated average recruitment rate in the most recent five years and the estimated SSB producing a particular cohort. For example, the abundance at age 4 at the start of 2018 was obtained based on the average recruitment rate to age 4 for the 2009 to 2013 cohorts and SSB in 2012. Prior to the 2016 assessment, this was done outside of the model. In this assessment, this was incorporated within the model, thus accounting for additional uncertainty. However, these estimates still do not account for the uncertainty associated with the assumption the recruitment rates for these terminal cohorts equal the average rates for the preceding five cohorts.

### 4.2 SPRING SPAWNER RESULTS

Residual patterns were similar to those observed for the corresponding model in the 2016 assessment and indicated an acceptable fit of the model to the age-disaggregated CPUE (Fig. 13). The fit to the CPUE index remained far superior compared to the 2016 model assuming no non-stationarity in M and q and to the model allowing time-varying M (see Fig. 4 in Swain 2016a). The fit to the acoustic index also remained similar to that of the 2016 model, though blocking of negative and positive residuals is now slightly more pronounced for this index. Fits to the age-aggregated indices lead to the same conclusions (Fig. 14). The retrospective pattern of this model also remains acceptable, with no progressive changes in past estimates in a consistent direction as additional data are added to the model (Fig. 15).

The limit reference point (LRP) for NAFO Div. 4T herring is $\mathrm{B}_{\text {recover }}$, which is the lowest biomass from which the stock has been observed to readily recover. It is calculated as the average of the four lowest spawning stock biomass (SSB) estimates in the early 1980s (i.e., 1980-1983).

Consequently, this value is model dependent. If the model changes, stock biomass may be rescaled upwards or downwards. With the model change in 2016 there was a slight change in biomass in the 1980s. Thus the LRP was re-calculated. The revised LRP is $19,250 \mathrm{t}$, slightly lower than the former value of $22,000 \mathrm{t}$.

Catchability to the fishery and to the CPUE index averaged about 0.006 in the 1990s, increasing to a peak of approximately 0.032 from 2007 to 2017 (Fig. 16). Estimated catchability increased as the stock declined below 60,000 t of spawner biomass (Fig. 17). Recent estimates (20082016) of spawning stock biomass (SSB) were slightly lower than those estimated in the 2016 assessment (Fig. 18; Table 20). The Monte Carlo Markov Chain (MCMC) estimates of SSB at the beginning of 2017 and 2018 were 11,744 t $95 \%$ confidence interval: $6,463-28,171$ ) and $12,446 \mathrm{t}$ ( $95 \% \mathrm{CI}: 6,418-30,365$ ), respectively. The estimate for 2018 is $65 \%$ of the LRP. The probabilities that the projected SSB was above the LRP at the start of 2017 and 2018 were $<11 \%$ and $15 \%$, respectively.

Recruitment rates (the number of recruits divided by the SSB that produced them) were unusually high in the early 1980s (Fig. 19). This may reflect compensatory increases in recruitment success at low SSB and/or other ecosystem changes promoting good recruitment (e.g., reduced predation on larvae by other collapsed pelagic fishes; Swain and Sinclair 2000). Recruitment rates have been much lower since then, though periods of moderately high recruitment rates occurred in the late 1980s and early 1990s and between 2005 and 2011. Recruitment rates were slightly lower in 2012 but appear high in 2013 though the confidence intervals are very high for that year. Recruitment rates during the recent period of low abundance are considerably lower than in the earlier low-abundance period. This may reflect effects of climate change (Melvin et al. 2009) or other ecosystem changes.

Estimated abundances of age 4 herring at the start of 2017 and 2018 were higher than those since 2005 (Fig. 20; Table 21), however the confidence intervals in 2017 are quite large. The age 4 abundance in 2018 depends on the assumption that recruitment rate for this cohort is the average of the rate for the preceding five cohorts. Recruitment rates and uncertainty vary among these five cohorts (Fig. 20). The error bar for 2018 in Figure 20 does not take into account the uncertainty in the recruitment rate for this cohort as it depends on the assumption that its recruitment rate was the average of the five preceding cohorts. If the recruitment rate of the 2013 cohort was instead low, like that of the previous cohorts, age-4 abundance in 2018 would resemble the low 2016 value.

The most recent estimate of spawner (4+) abundance is for 2017 , since the 2018 value depends on the recruitment rate assumed for the 2013 cohort. The maximum likelihood estimate (MLE) for 2017 is 82.9 million (Table 21), and the MCMC median is 80.2 million herring ( $95 \% \mathrm{Cl}: 42.3-206.5$ ), about 20\% of the average spawner abundance in 1985 to 1995.
Estimated exploitation rates were very high in 1980 and in most years from 2000 to 2011 (Fig. 21; F values in Table 22). Estimated exploitation rates exceeded the reference level (F0.1 = 0.35 ) in most years from 1988 to 2011 (Fig. 21). The estimated exploitation rate declined below F0.1 in 2012 to a low value of 0.19 and has since remained below F0.1 in subsequent years with the exception of 2013 (Table 22). Exploitation rates in 2015 to 2017 averaged 0.24 .

The SS population trajectory with respect to spawning stock biomass and fishing mortality levels is shown in Figure 22. The stock has been in the critical zone ( $\mathrm{SSB}<\mathrm{LRP}=19,250 \mathrm{t}$ ) since 2004 and experienced fishing mortalities above the F0.1 level until 2012. F has been below F0. 1 since 2014.

### 4.3 SPRING SPAWNER PROJECTIONS

The population model was projected forward for the two years to the start of 2020 and 10 years forward to the start of 2027 during the MCMC sampling of the joint posterior distribution of the parameters. This takes into account uncertainties in the parameter estimates. Projections were conducted at several levels of annual catch ( 0 to $3,000 \mathrm{t}$ in increments of 500 t ).

No model estimates are available for abundances at ages 2 to 4 in 2018. These are generally estimated in the projection using recruitment rates at ages 2 to 4 and estimates of the SSB producing each cohort. Projection results depend strongly on what recruitment rates are realized in the projection years. SS are the first recruited to the fishery at age 4, an age with very low catchability to the fishery. The estimates of age 4 recruits for the 2012 and 2013 yearclasses are preliminary, as the 2013 cohort has only been observed once (at age 4) and the 2012 cohort has been observed twice (at ages 4 and 5). Consequently, the cohort strength is highly uncertain for the 2013 cohort and only slightly less uncertain for the 2012 cohort. With additional years of observation, the strength of these year-classes will become less uncertain and may be revised. For example, in the 2016 assessment, the 2010 and 2011 cohorts were estimated to be very weak (i.e., produced by low recruitment rates), but with two additional years of data the recruitment rates that produced these cohorts appear to have been relatively strong.
Due to variable recruitment in recent years, projections were conducted under three different scenarios about recruitment during the projection period: (1) high recruitment, (2) low recruitment, and (3) mixed recruitment. The recruitment in the projections differs from the contemporary model as it does not use the highly uncertain estimate of the 2013 year-class recruitment. Recruitment rates were estimated to be relatively high for the 2006 to 2013 yearclasses. For the high recruitment rate scenario, the recruitment rate in each iteration of each year was randomly selected from those estimated for the 2007 to 2012 cohorts. The current period of high recruitment was preceded by a period of very weak recruitment rates from 1992 to 2005. It is possible that recruitment rates will decline back to this lower level during the projection period. Therefore, for the low recruitment rate scenario, recruitment rates were randomly selected from those estimated for the 1999 to 2005 cohorts. The mixed recruitment scenario contains a mixture of high and low recruitments rates. In this scenario, recruitment rates were randomly selected from those estimated for the 1999 to 2012 cohorts. This random selection was repeated in each of the 2,500,000 MCMC iterations. This procedure was also used to obtain estimates of age-2 abundance at the start of 2019 and 2020. For each iteration and each year, vectors of beginning of year weights at age in the population and weights at age in the fishery catch were randomly selected from the last five years (2013 to 2017).
Projections of SSB and ages 6 to 8 fully recruited F are shown in Figures 23 and 24, and the probabilities of meeting various objectives are given in Table 23 for each catch level.

### 4.3.1 Short term projections

Uncertainty in the projections was high and results depended on the assumed recruitment regime (Fig. 23 and 24). In both 2018 and 2019, SSB was expected to increase slightly at annual catches of 0 and 500 t assuming high recruitment, remain stable ( 0 t ) or decline ( 500 t ) assuming low recruitment, and increase ( 0 t ) or decline ( 500 t ) assuming mixed recruitment. At an annual catch of $1,500 \mathrm{t}$, SSB was expected to decline in all cases except in 2019 with high recruitment rates (when SSB remained roughly stable). At catches over $1,500 \mathrm{t}$, SSB was expected to decline in all cases.
The probability of an increase in SSB between the beginning of 2019 and the beginning of 2020 decreased from $80 \%$ at 0 t of catch to $49 \%$ at $1,000 \mathrm{t}$ of catch and $10 \%$ at $2,500 \mathrm{t}$ of catch under
the high recruitment scenario. At the mixed and low recruitment scenarios, the probability of the SSB increasing was $58 \%$ and $39 \%$ respectively at $0 t$ (Table 23). For the short term projections, all catch levels (including no catch) and recruitment rates resulted in little probability that SSB would exceed the LRP at the start of $2020(20 \%$ at high recruitment and $0 t$ of catch, $8 \%$ at $2,500 \mathrm{t}$; at low recruitment $6 \%$ at $0 \mathrm{t}, 2 \%$ at $2,500 \mathrm{t}$ ). In the short term there is no chance that the population would be at or above the Upper Stock Reference (USR) in 2020 even with no catch regardless of the recruitment scenario. Over the short term, the probability that age 6 to 8 fully recruited F would be greater than the removal rate reference level of $\mathrm{F} 0.1=0.35$ was small at $1,000 \mathrm{t}$ of catch ( $0 \%$ ), increasing to $9 \%$ at $1,500 \mathrm{t}$ of catch with low recruitment, and $57 \%$ at $2,500 \mathrm{t}$ of catch with low recruitment. Since 2009, the TAC has been set to $2,000 \mathrm{t}$ annually. At $2,000 \mathrm{t}$, the probability of an increase in SSB ranges from 0\% (low recruitment) to 19\% (high recruitment). Furthermore, at $2,000 \mathrm{t}$ there is at most a $9 \%$ probability that SSB will exceed the LRP at the start of 2020.

### 4.3.2 Long term projections

By 2027, the probability of exceeding the LRP was most favorable under the high recruitment scenario and low catches ( $<1,500 \mathrm{t}$ ), however at the low recruitment scenarios even with no catch there was only a $13 \%$ probability of SSB exceeding the LRP (Table 23). With no catch, the probability that SSB will exceed the USR in 2027 is $11 \%$ in the high recruitment scenario, $0 \%$ in the low recruitment scenario, and $2 \%$ in the mixed scenario. At $2,000 \mathrm{t}$, the probability of SSB exceeding the LRP by 2027 ranges from $2 \%$ (low recruitment scenario) to $38 \%$ (high recruitment scenario). Furthermore at $2,000 t$ there is at most a $4 \%$ chance of reaching the USR by 2027 .

## 5. FALL SPAWNER COMPONENT ASSESSMENT

### 5.1 FALL SPAWNER MODEL

The FS component is assessed using a VPA model implemented using AD Model Builder (Fournier et al. 2011). The FS model incorporated ages 2 to $11+$ (i.e., 11 years and older) and began in 1978. Abundance of the plus group (11+) was estimated using the F-ratio method (Gavaris 1999). $M$ was assumed to be constant at 0.2 for all years and ages. Data inputs to the model included:

- fishery catches by region at ages 2 to 11+ (in numbers) (Table 6 and 10),
- catch-per-unit-effort (CPUE) index by region from 1986 to 2017 (4 to 10 years) (Table 15),
- fishery-independent acoustic survey index across the sGSL from 1994 to 2017 (ages 2 and 3) (Table 16),
- catch rates at age in experimental nets by region from 2002 to 2017 (ages 3 to 9 or 10) (Table 17),
- the proportion of gillnets with $25 / 8$ inch mesh (Fig. 11) and the relative selectivity to the gillnet fishery by age, year and mesh size in each region (Table 18), and
- multispecies bottom trawl survey index (RV index) across the sGSL from 1994 to 2017 (ages 4 to 6) (Table 19).
Model parameters included abundance at ages 5 to $11+$ at the beginning of 2018, $q$ at age to the fishery (i.e., the CPUE index, ages 4 to 10) and each of the indices, and the standard deviation (SD) of observation error at age for each of the indices. All parameters were estimated on the log scale.

Catchability to the fixed gear fishery was modelled as described in Swain (2016a, b). It was modelled as selectivity at age times fully recruited $q$. Fully-recruited $q$ was freely estimated for 1990 and then allowed to vary over time following a random walk. The $q$ deviations were assumed to be normally distributed with a mean of 0 and a standard deviation of 0.1. The objective function included a term penalizing departures of the $q$ deviations from 0 . Catchability and selectivity-at-age were estimated separately for each region.

Model estimates and their uncertainty were evaluated based on MCMC sampling, with every $500^{\text {th }}$ of $2,501,000$ samples saved. Indices for age 3 herring were available for each region in the final year (2017). This permitted estimation of the abundances of all mature ages (4+) at the beginning of 2018. Thus, an estimate of SSB for each region in 2018 can be obtained without using an assumed recruitment rate to estimate age 4 abundance in 2018. However, the age 4 abundance estimates for 2018 are based on single observations (the age-3 experimental net index for each regions), and uncertainty may remain high for these estimates. This is incorporated within the models, thus accounting for this uncertainty.

### 5.2 FALL SPAWNER RESULTS

Similar to the results of the previous assessments, residual patterns for the CPUE indices were not severe (Fig. 25), indicating an adequate fit to these indices. Nevertheless, there was a tendency to overestimate abundance at ages 8+ in the Middle region in the late1980s and early 1990s and to overestimate abundances at ages 4 and 5 in all regions in most years since 2010.Still the time varying catchability model provides an improvement compared to earlier models that assume constant catchability. Analysis of constant catchability models produced evidence of severe blocking of residuals, with negative residuals for nearly all age-year cells prior to 1995 and positive in most cells since 2005 (Swain, 2016b).
Residual patterns for the experimental net indices were similar to those for these indices in the 2016 assessment (Fig. 26). There was a block of negative residuals in 2003 to 2005 and positive residuals in 2008 and 2010 in the North region. As in 2015, a number of year effects were evident (e.g., 2004 in the North region, 2007 in the Middle region, and 2010 in the South region). Year effects were also evident in the RV and acoustic indices (Figs. 25 and 26). We were unable to use the experimental net data for the Middle region in 2017 as only a single net was set.

The limit reference point (LRP) for FS herring is $\mathrm{B}_{\text {recover, }}$ which is the lowest biomass from which the stock has been observed to readily recover, calculated as the average of the four lowest spawning stock biomass (SSB) estimates in the early 1980s (i.e., 1980-1983). Consequently, this value is model dependent. If the model changes, stock biomass may be re-scaled upwards or downwards. With the model change in 2014 there was a slight change in biomass in the 1980s. Thus the LRP was re-calculated. The revised LRP is $58,000 \mathrm{t}$, slightly greater than the former value of $51,000 \mathrm{t}$.

Fits to the age-aggregated CPUE indices were reasonably good, with predicted values consistent with the general trends in the indices (Fig. 27). Fits were also generally acceptable for the age-aggregated experimental net indices (Fig. 28). These indices were quite noisy particularly in the Middle region. In the South, the predicted values failed to capture an apparent increasing trend in the most recent years. Trends were minor for these short indices. The fit to the age-aggregated RV index and acoustic juvenile index were reasonable (Figs. 27 and 28) however predicted values tended to underestimate observed values in high biomass years (e.g., 2015 in the acoustic index (Fig. 27) or 2012 in the RV index (Fig. 28).

Similar to the 2016 model, retrospective patterns for the Middle and South regions were negligible (Fig. 29). The retrospective pattern was greatest in the North region, though not in a
consistent direction. Initially, the estimates for 2009 and 2010 decreased as data for 2011 to 2015 were added to the North model. Estimates for 2012 to 2014 tended to increase as data for 2012 to 2015 were added. Finally, the addition of data for 2016 and 2017 resulted in large declines in the estimates of SSB for 2009 to 2016. The changes in the estimates in the North with the addition of the 2016 and 2017 data have resulted in a substantial revision in the perceived status of this stock in the recent period (since about 2010). The addition of the most recent years of data resulted in the assessments from previous years being overly optimistic. As the North contains the largest biomass, this change means that the advice based on the total SSB for the sGSL has also been overly optimistic.
Estimated changes in fully-recruited catchability to the gillnet fishery differed between regions (Fig. 30). Catchability was lowest and varied little over time in the North region. Catchability in the South region increased over time, primarily between 1995 and 2010. In this region, q since 2010 has been 3.5 times greater than q prior to 1995 but has started to decrease in recent years. Estimated catchability was greatest in the Middle region until the late 2000s when it was surpassed by catchability in the South region. In the Middle region, fully-recruited q was at its lowest around 1990, and then increased to a level about three times as high by late-2010s. Estimates of catchability at age are shown in Figure 31 for the fishery (i.e., the CPUE index) and Figure 32 for the experimental nets. Catchability to the experimental nets was highest in the Middle region and lowest in the North region. Catchability in the South was similar to the North at young ages and slightly greater than the North at older ages. The patterns in relative catchability between regions for the experimental nets resemble those for the gillnet fishery in 1986 (e.g., q relatively low in the South) and contrast those for the gillnet fishery in 2014 (e.g., q relatively high in the South) (Fig. 32). There is a tendency for catchability to decline with an increase in population biomass among these three regions, but most of the variation in $q$ within the Middle and South regions is independent of stock biomass (Fig. 33). This suggests that much of the increase in q in these two regions is related to technological improvements and improved fishing tactics rather than density-dependent effects. The similarities in patterns in $q$ -at-age between the experimental nets and the CPUE index in 1986 but not in 2014 (Fig. 32) is consistent with this suggestion.
Estimated SSB in the North region was at a high level from the mid-1980s to the early 1990s, and declined to a moderate level from the mid-1990s to the late 2000s (Fig. 34; Tables 24 and 25). Estimated SSB in this region declined continuously from 2012 to 2017, with the median estimate reaching its lowest levels since the early-1980s. In the Middle region, estimated SSB increased gradually from 1980 to the late 2000s, but has declined consistently from 2009 to 2017 to reach the lowest level since 1980 (Fig. 34; Tables 26 and 27). SSB in the South region was at a relatively high level from about the mid-1980s to the late 2000s. However, estimated SSB declined from 2009 to 2015. In 2016, SSB began to increase in the South region, however, uncertainty in this region is very high (Fig. 34; Tables 28 and 29). This may be because there is less extensive and less reliable information from Fisherman's Bank as they did not participate in the experimental net project and there is a high frequency in nil fishery catches from this area in recent years. Nil catches are not incorporated in the CPUE index. Thus, estimates of SSB in the South region may be biased high for recent years. Summed over the three regions, the MLE at the start of 2018 is $112,268 \mathrm{t}$ (Table 30; 567.8 million herring, Table 31) and the MCMC median is $111,832 \mathrm{t}$ ( $95 \% \mathrm{CI}: 79,044-182,064$ ). The estimated probabilities that the SSB is in the cautious zone (SSB was below the USR of 172,000 t) at the beginning of 2017 and 2018 are $98 \%$ and $97 \%$, respectively (Fig. 35).
Estimated abundance of FS age 4 and older has declined in the North and Middle regions since 2013 and 2009 respectively (Fig. 36). To a large extent, this reflects drastic reductions in the recruitment of age 4 herring. In the South region, this abundance declined from 2004 to 2015
but has increased recently, however, uncertainty in the estimates for this region have been very high since 2016 (Fig. 36). In all three regions, estimated abundances of age 4 herring in the last four years (2015 to 2018) are among the lowest observed, comparable or lower than the low levels estimated for the late 1970s. The estimates for the start of 2018 are highly uncertain for the North and South regions. The 2018 estimates are based on single observations (age 3 catch rates in the experimental nets in 2017).

The three most recent estimates of recruitment rate (recruit abundance divided by the SSB producing them) were among the lowest observed in the North and Middle regions (the 2012 to 2014 cohorts in Figure 37). The estimates for these three cohorts were average in the South region, though these estimates were extremely uncertain (Fig. 37). Summed over all three regions, total recruitment rates for the 2012 to 2014 cohorts were among the lowest observed. In the previous assessment (Swain 2016a), the 2010 and 2011 cohorts were reported to be among the lowest observed. Nevertheless, in this assessment the values for the 2010 and 2011 cohorts are higher. This suggests that the most recent estimates of recruitment rate may be biased low.

Estimated fishing mortality for ages 5 to 10 (F5-10) declined in the North region since 2008, but in the Middle and South regions F5-10 remained relatively high and consistent until 2017 (Fig. 38). In the North region, F5-10 averaged 0.54 from 1995 to 2008, declining to an average of 0.20 for the period 2013 to 2017 (Table 32). In the Middle region, estimated F5-10 averaged 0.40 from 1995 to 2016, however, in 2017 F5-10 increased drastically to 0.95 (Table 33). In the South estimated F5-10 averaged 0.36 from 1996 to 2015 but then declined to an F5-10 of 0.10 (Table 34). The weighted average F5-10 over all three regions (weighted by regional abundance of 5 to 10 year olds) exceeded F0.1 (the reference level in the healthy zone above the USR) from 1994 to 2011 except in 2004 (Fig. 38, Table 35). It then declined to a level just below F0.1. Based on the population model, the probability that F5-10 exceeded F0.1 was $1.7 \%$ in 2016 and $20 \%$ in 2017.

The FS population trajectory with respect to spawning stock biomass and fishing mortality levels is shown in Figure 39. The stock was in the healthy zone (SSB > USR) in most years from 1984 to 2012 but has declined into the cautious zone (LRP < SSB < USR) since 2015. The fishing mortality rate exceeded the reference level in 18 of the 30 years in the 1984 to 2012 period.

### 5.3 FALL SPAWNER PROJECTIONS

The population model was projected forward to the start of 2020 during the MCMC sampling of the joint posterior distribution of the parameters. This takes into account uncertainties in the parameter estimates. Projection results depend strongly on what recruitment rates are realized in the projection years. No model estimates are available for abundances at age 2 in 2017 and ages 2 and 3 in 2018. When there is no direct information on the strength of cohorts appearing in projections, their strength is estimated based on the recruitment rates estimated for recent cohorts. This assumes that recruitment in the near future will be similar to that in the recent past. However, in our case, it appears that the most recent estimates of recruitment rate are biased low and would result in overly pessimistic projections. On the other hand, if we base recruitment in the projection on recruitment observed relatively far in the past, it becomes more likely that the stock was in different recruitment regimes. An intermediate recruitment regime was used in projections based on 2008 to 2012 cohorts, which have been observed five to nine times in the observed data. Recruitment rates were randomly selected from the 2008 to 2012 cohorts. This random selection was repeated in each of the 200,000 MCMC iterations. For each iteration, vectors of beginning of year weight-at-age in each region, weight-at-age in the fishery catch for each region, and partial recruitment at age to the fishery in each region were randomly
selected from the last five years. Projections were conducted at annual catch levels from 10,000 to $50,000 \mathrm{t}$ in increments of $2,000 \mathrm{t}$.

Summed over all three regions, the median value of SSB at the start of 2020 was below the USR at all annual catch levels between 10,000 and 50,000 t (Figs. 40 and 41; Table 36). The probability that SSB would be below the USR at the start of 2020 increased from $90 \%$ at a catch of $10,000 \mathrm{t}$, to $99 \%$ at a catch of $50,000 \mathrm{t}$. At a catch of $20,000 \mathrm{t}$ (the landings in 2017) in 2018 and 2019, this probability would be $94 \%$. The probability that SSB would be below the LRP in 2020 ranged from $0 \%$ at $10,000 \mathrm{t}$ to $17 \%$ at $50,000 \mathrm{t}$ (Table 36). An increase in SSB by $5 \%$ or more by 2020 would only be likely (i.e., probability > 50\%) at catches below 16,000 $t$ whereas a decrease by $5 \%$ or more is probable at catches of $24,000 \mathrm{t}$ and above.
At catch levels from 10,000 to 20,000 tin 2018 and 2019, the median value of weighted average F5-10 over all regions in 2019 was below 0.32 (Figs. 40 and 42; Table 36). The median increased from 0.13 at a catch of $10,000 \mathrm{t}$ to 1.36 at a catch of $50,000 \mathrm{t}$. At a catch of $20,000 \mathrm{t}$ (the landings in 2017), the median was 0.31 in 2019. The probability that F5-10 would be greater than 0.32 in 2019 was 0 at a catch of $10,000 \mathrm{t}$, increasing to $99.6 \%$ at a catch of $50,000 \mathrm{t}$. With a catch of $20,000 \mathrm{t}$ in 2018 and 2019 , this probability would be $46 \%$.

## 6. DISCUSSIONS AND CONCLUSIONS

### 6.1 SPRING SPAWNERS

As with the previous assessment, this assessment used a model for SS that allowed catchability to the fishery to vary over time (Swain 2016a). Estimated catchability increased sharply in the 2000s, reaching a level in 2007 that was about 5.5 times the level in the 1990s. Estimated catchability has remained at this high level since then. The increase in fishery catchability (q) in the 2000s appeared to be density dependent, which has been observed in other herring stocks (Winters and Wheeler 1985). Fishery catchability is often expected to increase as population size decreases (Paloheimo and Dickie 1964; Winters and Wheeler 1985; Swain and Sinclair 1994; Rose and Kulka 1999). This is expected to occur because the area occupied by a stock is expected to decrease as stock size decreases (MacCall1990) and fish harvesters target fish aggregations (e.g., spawning aggregations). Thus, the proportion of the stock removed by a unit of fishing effort is expected to increase as a declining stock becomes increasingly concentrated in a smaller area. In a gillnet fishery, net saturation at high abundance may also contribute to increased catchability at low population size. Finally, catchability by fisheries is expected to increase over time due to technological improvements and improvements in fishing tactics.
The SS component trajectory with respect to spawning stock biomass and fishing mortality levels is shown in Figure 22. Estimated SSB of SS has been below the LRP (19,250 t) since 2004, the median SSB estimate at the start of 2018 is $12,446 \mathrm{t}$. Considering the uncertainty in model estimates, the probability that the SSB was above the LRP at the start of 2018 is $15 \%$. Recruitment rates were high in the early 1980s but have been much lower since. Recruitment rates have been variable in recent cohorts. Recruitment rate was relatively low for the 2012 cohort and high for the 2013 cohort, though uncertainty in the 2013 estimate is very high. Estimated abundances of age-4 herring at the start of 2017 and 2018 were higher than those since 2005, though the uncertainty in these estimates is very high. The median estimate of SS (4+) abundance at the start of 2017 (the most recent full estimate) is about $20 \%$ of the average spawner abundance in 1985 to 1995. Exploitation rates (ages 6 to 8) were high (above the F0.1 removal rate reference level of $F=0.35$ ) from 1999 to 2011 but declined to a lower level since 2012. Once a stock has declined out of the healthy zone, fishing at the maximum removal rate is not advised. This stock is estimated to have been below the healthy zone since 1999.

Despite large uncertainty in the projections, the probability that SSB will remain below the LRP at the start of 2020 was high, even with no catch ( $>80 \%$ ). The probability that $F$ (ages 6 to 8 ) will exceed 0.35 in 2019 is low ( $0 \%$ ) with catches of $1,000 \mathrm{t}$ or less, increasing up to $57 \%$ (low recruitment scenario) with catches of $2,500 \mathrm{t}$. At catches of $2,000 \mathrm{t}$ (i.e., the spring TAC since 2009) all or most surplus production is being removed. At $2,000 \mathrm{t}$, the probability of an increase in SSB ranges from $0 \%$ (low recruitment scenario) to $19 \%$ (high recruitment scenario). Furthermore, at 2,000 $t$ there is at most a $9 \%$ probability that SSB will exceed the LRP.
By 2027, the probability of exceeding the LRP was most favorable under the high recruitment scenarios and low catches ( $<1,500 \mathrm{t}$ ), however at the low recruitment scenarios even with no catch there was little chance ( 0.13 ) of SSB exceeding the LRP. Even under the high and mixed recruitment scenarios, there is little probability (0.11) of SSB exceeding the USR by 2027 with no catch, at low recruitment there is $0 \%$ chance. At $2,000 \mathrm{t}$, the probability of SSB exceeding the LRP by 2027 depends on the recruitment scenario, ranging from $2 \%$ at low recruitment to $38 \%$ at high recruitment. Furthermore at $2,000 \mathrm{t}$ there is at most a $4 \%$ chance of reaching the USR by 2027 .

### 6.2 FALL SPAWNERS

As with the previous assessment, this assessment used a model that treated FS as independent populations in three spawning regions and allowed catchability to the fishery to vary over time (Swain 2016a, b). As discussed in the SS assessment, catchability to fisheries is expected to change over time for a number of reasons. When estimates from all three regions are included, there was a weak tendency for catchability to increase as population size decreased, as expected from theory (e.g. Winters and Wheeler 1985). However, the variation in estimated $q$ within the Middle and South regions was largely independent of population size. This lack of relationship and comparisons between estimated catchabilities to the fishery and the experimental nets suggest that increasing catchability to the fishery over time is due to technological improvements and improved fishing tactics.
The fall spawner component trajectory with respect to spawning stock biomass and fishing mortality levels is shown in Figure 39. Estimated SSB of FS was above the USR until 2013 but has declined since then. All three regions contributed to this overall decline. The median estimate of total SSB at the start of 2018 was well below the USR, though uncertainty in this estimate was high. The probabilities that total SSB was below the USR at the start of 2017 and 2018 were $98 \%$ and $99 \%$, respectively. Exploitation rates (ages 5 to 10) were high (above the F0. 1 removal rate reference level in the healthy zone of $F=0.32$ ) from 1994 to 2011 but declined to a lower level since 2012. Once a stock has declined out of the healthy zone it is advised that fishing should be at rates which are less than the maximum removal rate (F0.1). Based on the projections, the probability of an increase of $5 \%$ or more in SSB by 2020 is $50 \%$ with catches of $16,000 \mathrm{t}$ and $74 \%$ with catches of $10,000 \mathrm{t}$. The probability of a decrease by $5 \%$ or more is $20 \%$ with catches of $16,000 \mathrm{t}$ and $50 \%$ with $24,000 \mathrm{t}$. With a catch of $20,000 \mathrm{t}$ (the catch in 2017), the probability that total SSB (i.e., summed over regions) will be below the USR at the start of 2020 is $94 \%$. With this catch in 2018 and 2019, the probability that $F$ for ages 5 to 10 would exceed $F=0.32$ in 2019 is $46 \%$.

## 7. SOURCES OF UNCERTAINTY

Fishery dependent indices, such as the commercial gillnet CPUE indices, may not be proportional to abundance due to changes in catchability over time. On one hand, catch rates can remain elevated despite decreases in abundance (increased catchability) due to contractions in stock distribution and targeting of aggregations by fishing fleets, and due to
improved fishing technology and fishing practices. On the other hand, catch rates can be negatively affected by boat limits, saturation of nets at high abundance and closure of prime fishing areas that redirect fishing effort to other locations. Catch rates calculated on the basis of realized landings and available fishing effort information would be subject to such effects. The estimation of time-varying catchabilities in the SS and FS assessments accounts for some of the effects listed above.

The commercial CPUE calculations are subject to uncertainty. The estimates are based on regional average seasonal values of fishing effort data (number of nets, number of hauls, and net length of gillnets) from the telephone survey and not trip-specific information. Trips with no catch are not documented prior to 2006 and therefore not incorporated in the effort data. A CPUE index for this time period should be calculated with the null tows for comparison with the traditional CPUE index. No information is collected on the soak time of nets. There are also potential inconsistencies in the reporting of effort data within and among regions and seasons.
The new modelling approach considers the dynamics of FS herring in three regions. The dynamics are modelled independently among regions and assume closed populations after recruitment at age 2 . This is a strong assumption that can have consequences on regionspecific estimates of abundance and dynamics. Empirical evidence for spawning bed fidelity has been documented in FS herring based on tagging studies. Nevertheless, elemental analyses of otolith structures did not detect region-specific differences among FS despite showing distinct differences between SS and FS in the sGSL. Genetic research has been unable to identify population-level differences between regions for fall spawners (Lamichhaney et al. 2017).

The weight-at-age of herring has declined and remains at near record low levels. The causes of these declines in weight-at-age and the consequences to recruitment rate are unknown.

Catches of herring in bait fisheries are presently not accounted for in the assessments of either SS or FS components. Catches in these fisheries are meant to be recorded in harvester logbooks but compliance with the requirement to complete and return logbooks to DFO is low. Catches of herring in the bait fishery are expected to be much lower than landings in the commercial fishery, nonetheless this unaccounted fishing mortality constitutes a source of uncertainty in the total fishing mortality.
Uncertainty in recruitment rate in both the SS and FS leads to uncertainty in projections as these are heavily reliant on the recruitment rate selected. In this assessment, we used various recruitment scenarios in the SS assessment to account for variation in recruitment rates among years. In the FS assessment, we used an intermediate recruitment rate as it appears that the most recent estimates of recruitment rate are biased low and would result in overly pessimistic projections.
The model assumes that natural mortality ( $M$ ) was constant over time. Retrospective patterns from previous assessments indicated a change in dynamics over time which could be because of changes in catchability $(q)$ or $M$. A model that incorporated time-varying change in $q$ provided a better model fit to address non-stationarity in the stock compared to a model that varied $M$. This does not mean that $M$ did not change but the current data and information used in the model only resolve one or the other. Future research should also consider whether $M$ has changed in this ecosystem and what information could be used to incorporate this dynamic in the population model.
In the previous assessment, the FS abundances were declining and the estimate at the end of 2015 was just below the USR. In this assessment, the median of the 2014 and 2015 estimates are below the USR. The declining trend in status has continued into 2018. Given this decline in absolute level of abundance from the previous assessment, it is possible that the current
biomass values from the model are overestimated. This overestimation of the biomass will result in an underestimate of the risk of failing to achieve defined management objectives for different catch options for 2018 and 2019 although the extent of the bias is not known.

## TABLES

Table 1. Landings (t) of NAFO Div. 4T herring in the spring and fall fisheries by gear (fixed and mobile) and spawning group (SS = spring spawners and FS = fall spawners). TAC allocations are also provided. Total catches highlighted in grey indicate years and stocks where the total catch exceeded the TAC.

| Year | Spawning group | Spring fishery |  | Fall fishery |  | $\begin{gathered} \text { Annual 4T } \\ \text { catch } \end{gathered}$ | Annual 4 Vn catch | Total catch 4TVn | TAC 4TVn |

Table 2a. Commercial herring fishery samples collected, number of fish processed for age ( $N$ ), landings ( $t$ ), and \% TAC landed by gear type (fixed gear and mobile gear), and zone in the spring (April 1-June 30) and fall (July 1-December 31) herring fisheries of NAFO Div. 4T in 2016. These data are used to derive the 2016 catch-at-age and weight-at-age matrices for NAFO Div. $4 T$ herring.

Table 12. Percent of annual fishing days with no gillnet catch of Atlantic Herring as reported from the telephone survey for the main fishing areas in the spring and fall fisheries in NAFO Div. 4T.

| Year | Spring fishery | Fall fishery |
| :---: | :---: | :---: |
| 2006 | 46.7 | 16.7 |
| 2007 | 40.0 | 28.8 |
| 2008 | 49.4 | 28.8 |
| 2009 | 23.2 | 17.5 |
| 2010 | 34.1 | 19.9 |
| 2011 | 26.2 | 27.3 |
| 2012 | 43.1 | 24.2 |
| 2013 | 36.3 | 22.8 |
| 2014 | 29.6 | 31.5 |
| 2015 | 16.2 | 40.9 |
| 2016 | 27.8 | 23.9 |
| 2017 | 39.8 | 40.5 |

Table 13. Results of the multiplicative general linear model applied to the fishery catch-per-unit-effort data for the Atlantic Herring spring spawners (NAFO Div. 4T) and fall spawners (by fishing region in NAFO Div. 4T).

| Spawner group | Area | $R^{2}$ | $F_{\text {year }}$ | $P_{\text {year }}$ | $F_{\text {week }}$ | $P_{\text {week }}$ | $F_{\text {area }}$ | $P_{\text {area }}$ |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Spring | Div. 4T | 0.44 | 22.3 | $<0.0001$ | 18.9 | $<0.0001$ | 51.8 | $<0.0001$ |
| Fall | North region | 0.57 | 3.3 | $<0.0001$ | 18.4 | $<0.0001$ | - | - |
| Fall | Middle region | 0.68 | 6.2 | $<0.0001$ | 13.2 | $<0.0001$ | - | - |
| Fall | South region | 0.52 | 4.5 | $<0.0001$ | 13.1 | $<0.0001$ | - | - |

Table 14. Spring spawner (SS) Atlantic Herring fixed gear age-disaggregated mean catch-per-unit-effort values (number per net-haul) for NAFO Div. 4T.

|  | Age (years) |  |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |

Table 20. Maximum likelihood estimates (MLEs) of beginning of year spring spawner Atlantic Herring biomass (t) for NAFO Div. 4T. Shading indicates values that are not directly estimated by the model. These values are calculated using the average of the five most recent estimates of recruitment rate (recruits/SSB). Note that MLEs may differ slightly from the MCMC medians reported in the text.

Table 21. Maximum likelihood estimates (MLEs) of beginning of year spring spawner Atlantic Herring abundance (number in thousands) for NAFO Div. 4T. Shading indicates values that are not directly estimated by the model. These values are calculated using the average of the five most recent estimates of recruitment rate (recruits/SSB). Note that MLEs may differ slightly from the MCMC medians reported in the text.

Table 23. Probabilities of various population states of spring spawning Atlantic Herring from NAFO Div. $4 T$ at the beginning of 2019 and 2020 (for SSB) or 2018 and 2019 (for F) based on projections under various recruitment scenarios (1-high recruitment, 2 - low recruitment, 3 - mixed recruitment) and at different levels of annual catch. The abbreviation "na" signifies not examined.
(1) High recruitment scenario

| Population state | Year | Catch option (t) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | 500 | 1,000 | 1,500 | 2,000 | 2,500 | 3,000 |
| SSB increasing | 2018 | 0.91 | 0.80 | 0.63 | 0.44 | 0.28 | 0.16 | na |
|  | 2019 | 0.80 | 0.66 | 0.49 | 0.32 | 0.19 | 0.10 | na |
| SSB > LRP | 2019 | 0.16 | 0.15 | 0.13 | 0.12 | 0.11 | 0.10 | na |

Table 35. Maximum likelihood estimates of the instantaneous rate of fishing mortality (F) by age of fall spawner Atlantic Herring in NAFO Div. 4T. F5-10 is the abundance-weighted average F for ages 5 to 10 years. No estimates ("na") are available for the shaded cell.

Table 36a. Projections of fall spawning Atlantic Herring biomass (kt) in NAFO Div. 4 T and biomass relative to population status objectives, expressed as probabilities, for various annual catch levels in 2018 and 2019. The same catch is assumed for 2018 and 2019. Spawning stock biomass (SSB) is the beginning-of-year median estimate from MCMC sampling. LRP is the limit reference point ( $58,000 \mathrm{t}$ of SSB) and USR is the upper stock reference (172,000 $t$ of SSB).

| Catch <br> (kt) | Projected SSB (kt) |  | Probability SSB < USR |  | Probability$S S B<L R P$ |  | Probability SSB > SSB 2018 |  | Probability 5\% increase in SSB |  | Probability 5\% decrease in SSB |  |

FIGURES

Figure 1. Southern Gulf of St. Lawrence herring fishery management zones (a - upper panel), Northwest Atlantic Fisheries Organization (NAFO) divisions $4 T$ and 4Vn, where purple represents the North region, blue $=$ Middle region, and green $=$ South region (b-middle panel), and geographic areas used in the telephone survey of the herring gillnet fishery (c - lower panel).

Figure 2. Reported landings (t) of southern Gulf of St. Lawrence Atlantic Herring (spring and fall spawners combined) by NAFO division (a - upper panel), by gear fleet (b - middle panel), and by fishing season (c lower panel), 1978 to 2017. In all panels, the corresponding annual total allowable catch (TAC; t) is shown. For landings by season, the landings in Div. 4Vn were attributed to the fall fishing season. Data for 2016 and 2017 are preliminary.

Figure 3. Estimated landings (t) of the spring spawner component (SS) (left column) and fall spawner component (FS) (right column) of Atlantic Herring from the southern Gulf of St. Lawrence, 1978 to 2017. The upper row (panels a, d) shows the estimated landings by gear type and the proportion of the landings attributed to the fixed gear fleet by spawner component. Also shown in these panels is the TAC for the spawner component (red symbols) for 1991 to 2017. The middle row (panels b, e) shows the estimated landings of herring in the fixed gear fleet that occurred in the spring fishery season (panel b) and the fall fishery season (panel e) as well as the proportion of herring landed in the corresponding fishing season. The lower row (panels c, f) shows the estimated landings of herring in the mobile gear fleet that occurred in the spring fishery season (panel c) and the fall fishery season (panel f) as well as the proportion of herring landed in the corresponding fishing season. For the mobile gear landings by season, the landings in NAFO Div. 4Vn were attributed to the fall fishing season. Data for 2016 and 2017 are preliminary.

Figure 4. Catch-at-age (number of fish) of the spring spawner component of Atlantic Herring from the fishery, all gears combined, in NAFO Div. 4T for 1978 to 2017. The size of the bubble is proportional to the catch numbers by age and year. The diagonal line represents the most recent strong year-class (1991).

Figure 5. Bubble plots of fishery catch-at-age (number of fish) of thje fall spawner component of Atlantic Herring, by region (upper panel North, middle panel Middle, lower panel South) for mobile gear and fixed gear combined, in NAFO Div. 4T for 1978 to 2017. The size of the bubble is proportional to the number of fish in the catch by age and year. The values indicated at age 11 represent catches for ages 11 years and older.

Figure 6. Mean weight (kg) of Atlantic Herring for ages 4, 6, 8, and 10 of spring spawners (left panels) sampled from catches in the spring season and fall spawners (right panels) sampled from catches in the fall season from mobile (upper panels) and fixed (lower panels) commercial gears, in NAFO Div. 4T for 1978 to 2017.

Figure 7. Bubble plot of spring spawner Atlantic Herring fixed gear catch-per-unit-effort values (number per net-haul per trip) at age from NAFO Div. 4T for 1990 to 2017. The size of the bubble is proportional to the maximum CPUE index value.

Figure 8. Fixed gear age-disaggregated catch-per-unit-effort indices (number per net-haul per trip) of fall spawner (FS) Atlantic Herring by region (upper panel North, middle panel Middle, and lower panel South), from NAFO Div. 4T for 1986 to 2017. The size of the bubble is proportional to the maximum CPUE index value.

Figure 9. Bubble plot of the fisheries-independent acoustic survey abundance-at-age indices (number of fish) for fall spawner (upper panel; ages 2 and 3) and spring spawner (lower panel; ages 4 to 8) Atlantic Herring for NAFO Div. 4T from 1994 to 2017.

Figure 10. Bubble plots of the experimental gillnet catch-at-age indices (numbers per hour) of fall spawner Atlantic Herring by region (upper panel North, middle panel Middle, and lower panel South) for NAFO Div. $4 T$ from 2002 to 2017. The size of the bubble is proportional to the maximum CPUE index value.

Figure 11. Variations in the proportions of gillnets with mesh sizes $2 \frac{5}{8}$ inches used in the fall fixed gear fishery of AtlanticHherring by region for NAFO Div. $4 T$ from 1986 to 2017. It is assumed that all other nets used were of mesh size $23 / 4$.

Figure 12. Multispecies bottom trawl survey abundance index (number of fish per standardized tow) for fall spawning Atlantic Herring of ages 4 to 6 years for NAFO Div. 4T from 1994 to 2017.

Figure 13. Residuals (observed - predicted indices) for population models of spring spawner Atlantic Herring in NAFO Div. 4T. The upper panel shows residuals for the CPUE index and the bottom panel shows residuals for the acoustic index. Rows are for ages and columns are for years. Circle radius is proportional to the absolute value of residuals. Black circles indicate negative residuals (i.e., observed $<$ predicted) and white circles indicate positive residuals.

Figure 14. Observed (circles) and predicted (lines and shading) age-aggregated CPUE (upper panels) and acoustic (lower panels) indices for the model of spring spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling.

Figure 15. Retrospective patterns in estimated spawning stock biomass (SSB, kt) of ages 5 to 10 for spring spawner Atlantic Herring in NAFO Div. 4T.

Figure 16. Estimated fully-recruited catchability to the CPUE index for spring spawner Atlantic Herring for NAFO Div. 4T. Lines show the median estimates and shading their $95 \%$ confidence interval based on MCMC sampling.

Figure 17. Fully-recruited catchability of Atlantic Herring to the spring gillnet fishery in relation to estimated spring spawner spawning stock biomass (SSB) for NAFO Div. $4 T$.

Figure 18. Estimated spawning stock biomass (SSB, kt) of the spring spawner component of Atlantic Herring in NAFO Div. 4T. Circles show the maximum likelihood estimates (MLEs). The solid line is the median MCMC estimate and shading its $95 \%$ confidence interval. The red dashed horizontal line is the Limit Reference Point (19,250 t of SSB). The blue dashed line shows the estimates from the 2016 assessment.

Figure 19. Recruitment rates for age 2 (circles) and age 4 (bars) recruits for the 1978 to 2013 cohorts of spring spawner Atlantic Herring in NAFO Div. 4T. Vertical lines indicate 95\% confidence intervals.

Figure 20. Estimated beginning-of-year abundance (millions) of 4 year old (blue bars) and 4 years and older (line) Atlantic Herring spring spawners in NAFO Div. 4T. Bars and the line show the median MCMC estimate and vertical lines or shading its 95\% confidence interval. Age-4 abundance in 2018 (the red bar) was estimated assuming the recruitment rate for this cohort was the average of the rates for the preceding five cohorts.

Figure 21. Estimated exploitation rate of spring-spawning Atlantic Herring aged 6 to 8 years in NAFO Div. 4T. Circles are the median estimates based on MCMC sampling and vertical lines their 95\% confidence intervals. The red horizontal line shows the reference level ( $F 0.1=0.35$ ) exploitation rate ( 0.295 ).

Figure 22. The population trajectory of the NAFO Div. 4T spring spawner Atlantic Herring expressed as the estimated spawning stock biomass (SSB) relative to the estimated fishing mortality rates for ages 6 to 8 years. The solid red vertical line is the Limit Reference Point (LRP; SSB $=19,250 t$ ), the green dashed vertical line is the Upper Stock Reference (USR; SSB $=54,000 t$ ), and the orange dashed horizontal line is the removal rate reference (FO.1 $=0.35$ ) in the healthy zone when SSB > USR. Point labels are years ( $83=1983,0=2000$ ). Colour coding is from blue in the 1970 s and early 1980 s to red in the 2000s.

Figure 23. Projected spawning stock biomass (SSB in kt) of spring spawner Atlantic Herring in NAFO Div. $4 T$ for three recruitment scenarios (columns) and three catch levels (rows) in 2018 and 2019. Lines show the median estimates of the beginning-of-year SSB and shading the $95 \%$ confidence intervals of these estimates (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. The red horizontal line is the limit reference point (LRP).

Figure 24. Projected ages 6 to 8 fishing mortality rate (F) of spring spawner Atlantic Herring in NAFO Div. $4 T$ for three recruitment scenarios (columns) and three catch levels (rows) in 2018 and 2019. Lines show the median estimates and shading their 95\% confidence intervals (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. The red horizontal line is the removal rate reference level (FO.1) corresponding to $F=0.35$.

Figure 25. Commercial gillnet CPUE index residuals (observed - predicted indices) by region (cpueN = North; cpueM = Middle; cpueS = South) and residuals between predicted and observed indices from the acoustic survey (Acoustic, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. Rows are for ages and columns are for years. The circle radius is proportional to the absolute value of the residuals. Black circles indicate negative residuals (i.e., observed < predicted) and white circles indicate positive residuals.

Figure 26. Experimental gillnet index residuals (observed - predicted indices) by region (exptIN = North; exptIM = Middle; exptlS = South), and residuals between predicted and observed indices from the RV survey (RV, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. Rows are for ages and columns are for years. The circle radius is proportional to the absolute value of residuals. Black circles indicate negative residuals (i.e., observed < predicted) and white circles indicate positive residuals.

Figure 27. Observed (circles) and predicted (lines and shading) age-aggregated commercial gillnet CPUE indices by region (CPUE North, CPUE Middle, CPUE South) and acoustic indices (Acoustic, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling.

Figure 28. Observed (circles) and predicted (lines and shading) age-aggregated experimental gillnet indices by region (North, Middle, South) and RV indices (RV, all regions combined) for fall spawner Atlantic Herring in NAFO Div. 4T. The lines show the median predicted indices and the shading the $95 \%$ confidence intervals of the predictions based on MCMC sampling.

Figure 29. Retrospective patterns in spawning stock biomass (SSB) of fall spawner Atlantic Herring within the three regions (North, Middle, South) and overall (Total) in NAFO Div. $4 T$.

Figure 30. Estimated fully-recruited catchability of fall spawner Atlantic Herring for the commercial gillnet CPUE index by region (North, Middle, South) in NAFO Div. 4T. Lines show the median estimates and shading their 95\% confidence intervals based on MCMC sampling.

Figure 31. Estimated adjusted catchability (q) at age to the gillnet fishery in three regions (North, Middle and South) for fall spawner Atlantic Herring in NAFO Div. 4T. The adjusted catchability takes into account changes in mesh size and length at age as well as the changes over time in fully recruited $q$.

Figure 32. Catchability (q) at age to the experimental gillnets by region (upper left panel) compared to $q$ -at-age in the commercial gillnet fishery in selected years (1986, upper right panel; 2000, lower left panel; and 2014, lower right panel) for fall spawner Atlantic Herring in NAFO Div. 4T.

Figure 33. Fully-recruited catchability (q) in relation to spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring for the three regions in NAFO Div. 4T. For each region, the marker denotes the first year in the 1986 to 2017 time series.

Figure 34. Estimated spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring by region (North, Middle, South) and summed over regions (Total) in NAFO Div. 4T. The line and circles show the median estimates and the shading their 95\% confidence intervals. In the lower right panel, the upper horizontal line is the upper stock reference level (USR) and the lower horizontal line is the limit reference point (LRP).

Figure 35. Posterior distributions of estimated total spawning stock biomass (SSB, kt) of fall spawner Atlantic Herring in NAFO Div. 4T at the start of 2015 to 2018 based on MCMC sampling. In each panel, the dashed vertical line shows the Upper Stock Reference (USR $=172,000$ ) and $p$ is the probability that the $S S B$ will not be in the healthy zone ( $S S B<U S R$ ).

Figure 36. Estimated abundance (millions) of age 4 (histograms) and age 4+ (circle symbols and lines) fall spawner Atlantic Hrring in the three regions (North, Middle, South) and summed over regions (Total) of NAFO Div. 4T. Line and circles (age 4+) and bars (age 4) show the median estimates and shading or vertical lines show the 95\% confidence intervals.

Figure 37. Estimated recruitment rate (recruits per kg of SSB) at age 2 (circles) and at age 4 (bars) of fall spawner Atlantic Herring in the three regions (North, Middle, South) and summed over regions (Total) of NAFO Div. 4T. Line and circles (age 4+) and bars (age 4) show the median estimates and shading or vertical lines show the 95\% confidence intervals.

Figure 38. Estimated ages 5 to 10 instantaneous fishing mortality rate (F, left axes; annual exploitation rate right axes) of fall spawner Atlantic Herring in the three regions (North, Middle, South) and averaged over regions (Total; weighted by regional abundance at ages 5-10 years) in NAFO Div. 4T. Lines show the median estimates and shading their $95 \%$ confidence intervals. In the lower right panel, the horizontal line shows the reference removal rate ( $F 0.1 ; F=0.32$ ) that applies in the healthy zone.

Figure 39. Population trajectory of the fall spawner component of Atlantic Herring in NAFO Div. $4 T$ expressed as the spawning stock biomass (SSB) relative to the fishing mortality rates for ages 6 to 8 years. The solid red vertical line is the $\operatorname{LRP}(58,000$ t), the green dashed vertical line is the Upper Stock Reference ( $U S R=172,000 t$ ), and the orange dashed horizontal line is the removal rate reference ( $F 0.1$; $F=0.32$ ). Point labels are years ( $83=1983,0=2000$ ). Colour coding is from blue in the 1970 s and early 1980s to red in the 2000s.

Figure 40. Estimated and projected spawning stock biomass (SSB in kt; left column) and ages 5 to 10 fishing mortality rate (F) (right column) of fall spawner Atlantic Herring in NAFO Div. 4T for three annual catch levels (rows) in 2018 and 2019. Lines show the median estimates of the beginning-of-year SSB or the median estimates of $F$ in the year whereas shading shows the $95 \%$ confidence intervals of these estimates (based on MCMC sampling). Black and grey indicate the historical period and blue the projection period. In the left column, the blue horizontal dashed line is the upper stock reference (USR) and the red horizontal line is the limit reference point (LRP). In the right column, the red horizontal line is the removal rate reference level ( $F 0.1 ; F=0.32$ ).

Figure 41. Profiles of the estimated probabilities of the projected spawning stock biomass (SSB) of fallspawning Atlantic Herring at the start of 2019 and 2020 relative to stock status indicators for increasing levels of annual catch from 10,000 t to 50,000 tin 2018 and 2019. The stock status indicators are: a) the probability that SSB will be less than the USR at the start of 2019 (dashed line) and 2020 (solid line) (top left panel); b) the probability that SSB will be below the 2018 level (top right panel); c) the probability of a $5 \%$ increase above the 2018 level (lower left panel); d) the probability of a 5\% decrease below the 2018 level (lower right panel).

Figure 42. Probability profiles that the average fishing mortality rates for ages 5 to 10 (F5-10) in 2018 and 2019 will be greater than the reference removal rate (F0.1; $F=0.32$ ) at various annual catch levels of 10,000 t to 50,000 t for fall spawner Atlantic Herring in NAFO Div. 4T.

## APPENDICES

## APPENDIX A. AGE READING CONSISTENCY TEST

A new reader was trained in 2015 to become the primary reader who aged the 2016 and 2017 otoliths. A new secondary reader was also trained in 2017.
Yearly age reading consistency tests are done in order to evaluate and ensure the consistency of age reading over time. A sub-sample of pairs of herring otoliths from years 1993, 1994, 1996 and 2003 was re-aged, and the new ages were compared to the reference ages. Otolith samples were randomly selected for age-groups 1 to 11+ and from years between 1993 and 2003, gear types used and type of sample (commercial and research). In total, a final set of over 200 otoliths was used. Results are presented for the primary and secondary reader.

The results show an overall agreement of $86 \%$ and a coefficient of variation (CV) of $3.8 \%$ for the primary reader and an agreement of $85 \%(3.7 \% \mathrm{CV})$ for the secondary reader (Fig. A1). The CV is considered to be a more robust measure of the precision of age determination (Campana et al. 1995). Based on the reading bias plot, there was no bias present, and age determination is more variable for older (9+) herring (Fig. A1).

Figure A1. Comparison of Atlantic Herring ages in NAFO Div. 4T obtained during the validation test with the original ages assigned. Bars indicate $95 \%$ confidence intervals. Straight line indicates original ages.

## APPENDIX B. FISHERY-INDEPENDENT ACOUSTIC SURVEY RESULTS

The 2015 to 2017 acoustic surveys were carried out in the 4Tmno areas (i.e., Chaleurs-Miscou; Fig. B1) and the biomass of herring were estimated to be $157,373 \mathrm{t}$; 63,493 ; and 69,023 respectively. The distribution of herring in the area can also be seen in Fig. B1 and Table B1. The 2015 acoustic biomass index of the Chaleurs-Miscou area for the combined spring (SS) and fall (FS) spawner groups was among the similar to the highest seen in the history of the survey; however the biomasses in 2016 and 2017 were similar to values observed since 2006, and are near the lowest value of the time series (Fig. B2).

Midwater trawl samples were made where herring densities were greatest. The catch (length frequency) by set was weighted by the sum of acoustic herring densities recorded in the stratum or group of strata defined in the catch-at-age parameters as representing the biomass in that area. Using the herring densities recorded as the weighting factor is considered a better method as it does not depend on an estimated standardized amount of herring caught in a set of one nautical mile.

Table B1a. Atlantic Herring biomass densities and estimates by stratum and area from the fisheryindependent acoustic surveys conducted in 2015 in NAFO Div. 4T.

| Area | Stratum | Mean target strength (dB kg ${ }^{-1}$ ) | Stratum area (km ${ }^{2}$ ) | Mean backscatter ( $\mathrm{dB} \mathrm{m}^{-2}$ ) | Density ( $\mathrm{kg} \mathrm{m}^{-2}$ ) | $\underset{(\mathrm{t})}{\mathrm{Biomass}}$ | Std. Error (t) | Std. Error (\%) |

## APPENDIX C. SPAWNING GROUND ACOUSTIC SURVEY RESULTS

The spawning ground acoustic survey was first conducted in 2015, and has been every year since. It follows a stratified random design with a protocol consistent with the fisheryindependent acoustic survey. Six spawning grounds were identified: Gaspé, Miscou, Escuminac/Richibucto, West PEI, East PEI (Fisherman's Bank/North Lake), and Pictou (Fig. C1). Strata were defined on each spawning ground using the acoustic information collected in previous industry partnership studies. Strata were designed to be large enough to encompass the historical spawning grounds in each region. Transects were randomly generated within strata at a minimum of 400 m apart (Fig. C2).

Each fishing association selected one or two fish harvesters to conduct the acoustic surveys to quantify the biomass of fish schools using a hull-mounted 120 KHz single beam transducer Acoustic data from fishing vessels have been used to analyze school morphology characteristics, spatial patterns, relative changes in school density (Shen et al. 2008) and to develop estimates of abundance (Melvin et al. 2002; Honkalehto et al. 2011). In the sGSL, fishery acoustic data collected on Atlantic Herring spawning aggregations can be used to obtain relative nightly biomass estimates (Claytor and Allard 2001; Claytor and Clay 2001). For each region, the goal of the analysis is to estimate the relative spawning biomass from a set of nightly acoustic observations. Surveys were to be conducted prior and following the fishing season and during the weekend fishing closure where possible. Escuminac and West PEl regions did not have week-end fishing closures for the years covered by this study, so sampling was only possible before and after the fishing season. For 2017 and 2018, these regions should have weekend closures, allowing a complete sampling grid. Size and age frequency data to convert the acoustic data into biomass estimates were obtained from the experimental gillnet surveys. Nightly acoustic data were processed and analyzed for each region in order to obtain a nightly biomass estimate (Table C1 to C3), as described in Claytor and Clay (2001).

Figure C3 shows the mean nightly biomass per spawning ground for every year. Some regions/years show great variations in nightly fish biomass (Miscou and Gaspé 2016, Escuminac 2015). As not every sampling trip has been undertaken for different regions/years, the presence or absence of samples in the beginning or the end of the season will have a great impact on the mean. Escuminac and West PEl regions are especially sensible to this, as only two trips can be done per year in these regions. The proportion of the strata covered and the frequency of survey coverage varied among year and regions from complete strata coverage on a weekly basis to a complete absence of surveys for East PEI in 2015 (Tables C1 to C4 for details). Gaspé (except 2017, harvester's boat sank), Miscou and Pictou regions show good coverage of the sampling season with almost five samples every year (Table C4).

The results show lower nightly biomass for every year in the West PEI and East PEI regions. Pictou region shows intermediate nightly biomass when compared to all regions, with a descending trend from 2015 to 2017. For the Escuminac region, biomass can reach high levels as in 2015 with $15,238 \mathrm{t}$, but other years do not show such high biomasses. Again, the low sampling effort on this spawning bed cannot allow an adequate characterization of the biomass for the whole spawning season. The Gaspé region shows intermediate biomasses for 2015 and 2017 (only one survey in 2017), but elevated biomass in 2016. The Miscou region shows the same trend as Gaspé, with the highest mean nightly biomass of all the sGSL in 2016.

For this survey to be included in the assessment, surveys need to be consistent across regions and conscientiously carried out. Weekend closures in West PEI and Escuminac for the next years will help acquiring more samples from these spawning beds. Also, the beginning of the sampling season could be moved to earlier dates, as the first sampling dates generally show the highest biomasses with a descending trend until the end of the fishing season. Earlier sampling
would allow a better estimation of the spawner biomass throughout the complete spawning season.

Table C4. Number of individual acoustic sampling trips per year and region from the spawning ground acoustic surveys.

| Region | 2015 | 2016 | 2017 |
| :--- | :---: | :---: | :---: |
| Gaspé | 5 | 5 | 1 |
| Miscou | 5 | 5 | 4 |
| Escuminac | 2 | 2 | 1 |
| West PEI | 2 | 1 | 2 |
| Pictou | 5 | 5 | 4 |
| East PEI | 0 | 3 | 5 |
| Total | 19 | 21 | 17 |

Figure C1. Fall spawner Atlantic Herring spawning grounds surveyed during the industry spawning ground acoustic survey.

Figure C2. Surveyed transects covered during the Atlantic Herring spawning ground acoustic surveys (white lines).

Figure C3. Nightly Atlantic Herring biomass estimates (t; mean plus one standard error bar) by spawning ground from the spawning ground acoustic surveys during August to October, 2015 to 2017.

Figure C4. Season advancement expressed as the nightly Atlantic Herring biomass (t) (whole survey period estimate divided in six equal periods of 13 days) during August to October, from the spawning ground acoustic surveys conducted during 2015 to 2017.

## APPENDIX D. MULTISPECIES BOTTOM-TRAWL SURVEY RESULTS

Figure D1. Spatial distribution of Atlantic Herring catches (number per tow) from the September multispecies bottom-trawl survey in the southern Gulf of St. Lawrence. The dots indicate the location of fishing sets.

Figure D2. Abundance indices (mean, approximate $95 \%$ confidence limits, i.e. $\pm 2$ standard errors, as vertical lines) expressed as number per tow (left column) and weight (kg) per tow (right column) of Atlantic Herring <26 cm in length (top row) and $\geq 26 \mathrm{~cm}$ (bottom row) from catches in the September multispecies bottom-trawl surveys in the southern Gulf of St. Lawrence.

[^0]:    * Catch-at-age for the Edge fishery used samples collected in 4Tf during the multi-species bottom trawl survey.

[^1]:    * Catch-at-age for the Edge fishery used sampled collected in 4Tf during the multi-species bottom trawl survey.
