Abstract

This new surficial geology map product represents the conversion of Map 46-1989 (Aylsworth, 1990) and its legend only, using the Geological Survey of Canada's Surficial Data Model (SDM) version 2.3 (Deblonde et al., 2017). All geoscience knowledge and information from Map 46-1989 that conformed to the current SDM were maintained during the conversion process. Supplementary legacy information was added to complement the converted geoscience data. This combination of streams and field data from Wright (1967) and McMartin et al. (2013, 2016, 2017) that may be identified in the accompanying geodatabase. The purpose of converting legacy map data to a common science language and common legend is to enable and facilitate the efficient compilation, interpretation, management, and dissemination of geological map information in a structured and consistent manner. This provides an effective knowledge management tool designed around a geodatabase that can expand, following the type of information to appear on new surficial geology maps.

Résumé

Ce nouveau produit cartographique de la géologie des formations superficielles correspond à la conversion de la Carte 46-1989 (Aylsworth, 1990) et de sa légende unique, en utilisant le Modèle des données superficielles (MDFS) version 2.3 de la Commission géologique du Canada (Deblonde et al., 2017). Toutes les connaissances et l'information de nature géoscientifique de la Carte 46-1989 qui sont en conformité avec le modèle de données ont été conservées pendant le processus de conversion. Des données supplémentaires existantes ont été ajoutées pour compléter les données géoscientifiques converties. Il s'agit de stries glaciaires et de données de terrain tirées de Wright (1967) et de McMartin et al. (2013, 2016, 2017). Ces entités et données sont identifiées dans la géodatabase du présent produit cartographique. Le but de la conversion de cartes publiées antérieurement vers une langue scientifique commune et une légende commune est d'améliorer et de faciliter la compilation, l'interprétation, la gestion et la diffusion efficaces de l'information géologique cartographique en mode numérique de façon structurée et cohérente. Cette façon de faire offre un outil efficace de gestion des connaissances élaboré à l'aide d'une géodatabase qui pourra évoluer suivant le type d'information à paraître sur les nouvelles cartes des formations superficielles.

Author: Geological Survey of Canada
Geology based on air photo interpretation by J.M. Aylsworth
Geology conforms to Surficial Data Model v. 2.3 (Deblonde et al., 2017).
Data conversion by D.E. Kerr, 2012, 2016, 2017
Geomatics by GISMO Solutions Ltd. and C. Lai
Cartography by N. Côté
Scientific editing by A. Weatherston

Initiative of the Geological Survey of Canada, conducted under the auspices of Natural Resources Canada's Geo-mapping for Energy and Minerals (GEM) Program
Map projection Universal Transverse Mercator, zone 15
North American Datum 1983
Base map at the scale of 1:250 000 from Natural Resources Canada, with modifications
Elevations in metres above mean sea level
Mean magnetic declination 2018, 7°16'W, decreasing 4.8' annually
Readings vary from 5°27'W in the SW corner to 9°09'W in the NE corner of the map.

This map is not to be used for navigational purposes.
The Geological Survey of Canada welcomes corrections or additional information from users.

Data may include additional observations not portrayed on this map.
See map info document accompanying the downloaded data for more information about this publication.

QUATERNARY HOLOCENE

NONGLACIAL ENVIRONMENT

A Alluvial sediments, modernized: stream-deposited material within modern active drainage systems; "modern" is defined as the period since retreat of the sea, proglacial lakes, and glacial ice.

Alluvial sediments, undifferentiated: silt, sand, and gravel; variable thickness; deposited in channels and depressions; may include alluvium in terraces which form cut-offs due to present base level in glacial and marine sedimentary fill; when associated with glaciogenic sediments it occurs as flat areas in stream valleys or abandoned channels; when associated with marine sediments it occurs as flat areas consisting of modern alluvium mixed with marine silt and sand that were washed from slopes by wave action or deposited in the sea by meltwater streams; surface generally covered by fibrous peat on which mosses, sedges, and grasses grow; surface characterized by frost polygons and thaw ponds related to vertical ice wedges extending to a depth of 2-3 m.

L Lacustrine sediments, undifferentiated: silt and sand; variable thickness; permanently drained postglacial lake basin; may include deposits of silty sediments with up to 15% organic carbon.

NONGLACIAL AND GLACIAL ENVIRONMENT

MR Marine sediments: materials deposited in the Tyrrell Sea and glacial deposits modified by marine processes.

Md Beach and nearshore sediments: sand, gravel, cobbles, or boulders; generally well sorted; variable thickness; deposited as beaches, bars, spits, and ice-pushed ridges; surface characterized by sparse vegetation and orthogonal frost cracks.

M Deltaic sediments: sand, pebbly sand, and gravel; variable thickness; deposited in the Tyrrell Sea by glacial or nonglacial streams.

Marine sediments, undifferentiated: sand and silt; variable thickness; washed from slopes by wave action or deposited in the sea by meltwater or modern streams; appears only as secondary unit in complex polygons.

GLACIOFLUVIAL SEDIMENTS: water-sorted sediments deposited in, or around, or near a glacier, largely as a result of meltwater stream flow.

GFP Outwash plain sediments: sand and gravel; variable thickness; with terraced, hummocky, and kettle surfaces; deposited by subaerial meltwater streams in areas above local sea level; includes 1) sediment deposited between the esker ridges, 2) a surface of outwash plains, 3) a surface of outwash fans, 4) temporary floor 3) outwash fans, 3) outwash plains, and 4) materials on the floor or at the mouth of meltwater channels; sparsely vegetated.

Gf2 Subaqueous outwash-fan sediments: sand, fine gravel, and silt; variable thickness; deposited by subaerial meltwater streams in areas below the esker surface; deposited by subaqueous meltwater streams; vegetation is common sedge, grass, and moss growing on thin fibrous peat; surface characterized by thaw ponds and tundra polygons; difficult to differentiate from unit A.

Gfc Ice-contact sediments: sand and gravel; stratified; variable thickness; deposited near ice margins in, over, or around ice or ice tunnels, commonly as eskers, but includes isolated hummocky deposits of uncertain origin; many eskers are beaded or interrupted at irregular intervals by major bulges marking positions where deltaic or subaqueous fan deposition occurred during periods of ice retreat.

GF Glaciogenic sediments, undifferentiated: silt, sand, and gravel; variable thickness; deposited in or near a glacier; appears only as secondary unit in complex polygons.

Glaciogenic sediments (Till): poorly sorted till with distinctive forms deposited directly by glacial ice.

Hummocky till: diamict, variable thickness; till without significant boulder content occurring as low, rounded hummocks; includes ridges of till that are minor end moraines or erosion remnants beneath subparallel meltwater channels; exact origin unknown; may have formed in association with stagnant ice or in some places from erosion of till surfaces by streams in anastomosing meltwater channels; vegetation and periglacial features similar to those on Tb.

Tr Ridged moraine: diamict, in places sand and gravel; generally bouldery; variable thickness; ribbed (Rogen) moraine; forming hummocks and straight to sinuous ridges, generally less than 1 km long and 2–10 m high; ridges generally oriented at right angles and form trains parallel to direction of ice movement; may be beaded; may be symmetrical or asymmetrical; on one side facing down-ice; trains of ribs may terminate in drumlin fields and may be drumlinized in the transition zone; surfaces have sparse vegetation and generally a heavy cover of large boulders and mudballs where composed of till, and marked by frost cracks where composed of gravel.

Tv Till veneer: generally sandy, silty diamict; less than 1 m thick.

Till blanket: generally sandy, silty diamict; noncalcareous; grey till; variable thickness; includes areas of clay-rich red till; plain surface characterized by elevated peaty ridges, small shield hummocks, and grasses; at lake margins characterized by cobble-covered, 2 m wide rims separated by 2 m wide boulder-filled troughs; generally trending downslope to a water depth of about 2 m; may include prominent striped pattern on airphotos.

PRE-QUATERNARY

R Bedrock, undifferentiated: Precambrian intrusive igneous and metamorphic rocks, red volcanic rocks, and unmetamorphosed sedimentary rocks; surface comprises more than 80% outcrop; vegetation sparse; surface may be glacially rounded or covered by talus material; bedrock with less than 1 m of the surficial deposit indicated in complex polygons.

Complex units: two map-unit designators are used in cases where the surficial cover forms a complex area and the map units are too small to be mapped individually; the first designator is the general extent of the complex unit (e.g. Tv-R) designates an area of till veneer with numerous small bedrock outcrops. In such instances a dot (.) is used to separate the map-unit designators.

Stratigraphic relationship: a stratigraphic relationship is shown with two map-unit designators separated by a slash (/) (e.g. Tr-R designates ridged till overlying bedrock).

Felsenne

Geological contact, defined

Beach crest, bar, or ice-shoved ridge

Limit of marine submergence

Major meltwater channel, direction unspecified

Minor moraine ridge, undifferentiated, De Geer

Esker, direction known or inferred

Drumlinoid, fluting

Crag-and-tail

Hummock (hummocky moraine)

Striation:

Ice-flow direction unknown

Ice-flow direction known

Small bedrock outcrop

Station location, ground observation (see geodatabase)

Sample location (see geodatabase)
