IMAGE ANALYSIS STUDY OF THE MINERALS IN THE
SECONDARY ZINC CIRCUIT OF THE BMS CONCENTRATOR

by

William Petruk* and Michael R. Hughson**

ABSTRACT

Samples collected in September, 1979, from the secondary zinc circuit of the BMS concentrator were studied to determine the behaviour of the sphalerite, galena and chalcopyrite. The liberations and size distributions of the minerals were determined and the data were processed by the MATBAL 2 program to adjust the analysed values so that there would be a balance between amounts fed to and discharged from the flotation cells. A comparison of the results with similar data for samples collected in 1977 shows that sphalerite recovery was better from some cells and poorer from other cells. This suggests that monitoring the zinc content of the tailings from the cells would indicate when corrective steps need to be taken to maintain a constant recovery. It was also observed that large, free chalcopyrite grains were lost to the mill tailings as in 1977.

ÉTUDE PAR ANALYSE D'IMAGES DES MINÉRAUX DU CIRCUIT SECONDAIRE
DE RÉCUPÉRATION DU ZINC DU CONCENTRATEUR BMS

par

William Petruk* et Michael R. Hughson**

RÉSUMÉ

On a étudié des échantillons recueillis en septembre 1979 dans le circuit secondaire de récupération du zinc du concentrateur BMS, pour déterminer le comportement de la sphalérite, de la galène et de la chalcopyrite. On a déterminé la libération et la granulométrie des minéraux, et traité les données à l'aide du programme MATBAL 2 pour ajuster les valeurs analysées, de façon à maintenir un équilibre entre les quantités apportées aux chambres de flottation et les quantités provenant d'elles. En comparant ces résultats à des données similaires obtenues avec des échantillons recueillis en 1977, on a constaté que dans certaines cellules de flottation, on obtenait de plus grandes quantités de sphalérite que dans d'autres. Il est donc possible qu'en surveillant le taux de zinc dans les résidus provenant des cellules de flottation, on puisse déterminer quand effectuer un rajustement pour obtenir un taux constant de récupération de la sphalérite. En 1977, on a aussi constaté que de gros grains libres de chalcopyrite étaient perdus avec les résidus de traitement.

INTRODUCTION

The behaviour of minerals in the concentrator of Brunswick Mining and Smelting Corporation Limited (BMS) was studied by Petruk and Schnarr (1981) by analyzing samples that were collected in September 1977. Subsequently the secondary zinc circuit of the concentrator was slightly modified and resampled in September 1979 by R. Grant, Project Development Metallurgist, BMS. The 1979 samples were studied in the same way as the 1977 samples but the analyses were extended. In the initial study, material balances were calculated from the chemical analysis data, using MATBAL 2 (Laguitton 1980), and the liberations and size distributions of the sphalerite in the feed, concentrate and tailings for each bank of flotation cells were determined with the Quantimet 720 image analyser. In the current study the procedure was repeated, but liberations and size distributions were also determined for the galena and chalcopyrite and the materials balance procedure was applied to the image analysis data as well as to the chemical analyses.

FLOWSCHEM, ASSAYS AND MATERIALS BALANCE

The flowsheet of the secondary zinc circuit is shown in Fig. 1. The weight per cent (wt %) of material and assays and distributions of zinc, lead and copper in the zinc concentrate and tailings products are given in Table 1. Details for assays and distributions in the cells are given in Table 2. A materials balance analysis was performed with the MATBAL 2 program using the assay values (raw data) to determine the weight per cent of material going through each point in the circuit (Table 2). To obtain a materials balance, the MATBAL 2 program adjusts the chemical analyses to best fit by applying a weighting to each analysed value because there is always some analytical and sampling error. The balanced values meet the condition that the amount of material, element or mineral, discharged from a bank of flotation cells as concentrate plus tailings is equal to the amount fed to the cells. The balancing program is recycled by the computer

until the change in values between successive cycles is less than 0.01. The adjusted chemical analyses, balanced weight per cent of material, and recovery of each element at each sample point are listed in Table 2. Comparable values for the 1977 study are included in the table.

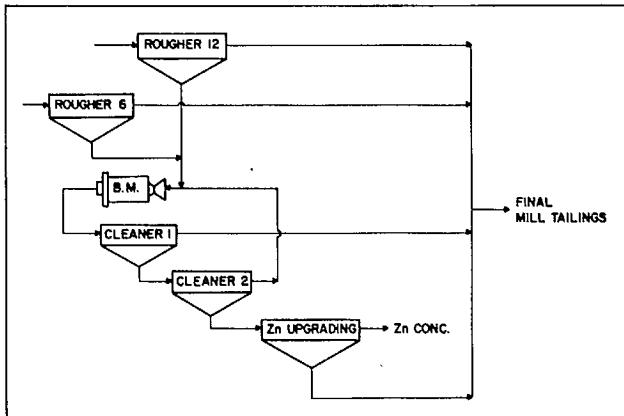

Fig. 1 — Flowsheet of secondary zinc circuit.

All the zinc, lead and copper in each sample were assumed to be in sphalerite, galena and chalcopyrite respectively. This is because no other zinc and lead-bearing minerals were found and only a trace amount of copper-bearing tetrahedrite was present. The quantity of tetrahedrite was so small that it could not account for more than 1% of the copper and was below the limit of analysis.

MINERAL LIBERATION AND RECOVERIES

The proportions of sphalerite, galena and chalcopyrite that were present as free and unliberated grains were determined with a Quantimet 720 image analyser by measuring the surface areas of mineral grains observed in about 50 fields of the polished section using a 16X objective at a magnification of 1.6. At this magnification, the minimum size of grain detected was $1.5 \mu\text{m}$ in diameter and it had a surface area of about $2.25 \mu\text{m}^2$. Each field analysed was $370 \mu\text{m}$ by $290 \mu\text{m}$ and had a surface area of about $107,300 \mu\text{m}^2$. Therefore, the total surface in 50 fields was $5,365,000 \mu\text{m}^2$ or about 5 mm^2 . About 35% of the surface area analysed consisted of mineral grains and the remainder was mounting medium. Each field analysed

contained about 1000 to 1500 grains, 1.5 to 100 μm in diameter. This is equivalent to analysing about 6 to 10 grains of chalcopyrite per field in a sample containing 0.35 wt % Cu, 6 to 10 grains of sphalerite per field in a sample containing 0.6 wt % Zn, and 4 to 6 grains of galena per field in a sample containing 0.9 wt % Pb. Proportionally more or fewer grains were analysed when the assays were respectively higher or lower. Since the zinc assays varied from about 1.5 to 53 wt %, about 1000 to 35 000 sphalerite grains were analysed in the respective samples. Similarly 0 to 1900 galena grains and about 40 to 500 chalcopyrite grains in the respective samples were analysed.

The analysed values were corrected to account for the slicing effect that causes unliberated grains to appear free in polished sections (Petruck, 1978). The correction was: the corrected per cent of unliberated grains equals the analysed per cent of unliberated grains times 1.15. The corrected per cent of free grains is, therefore, 100% minus corrected per cent unliberated. The corrected percentages of free

sphalerite, galena and chalcopyrite (as observed) are listed in Table 3. The corrected percentages of free mineral grains were adjusted to a materials balance by using the MATBAL 2 so that the amount of free mineral grains entering each cell was equal to the amount discharged. This was done by converting the corrected percentage of free sphalerite, galena and chalcopyrite to a weight per cent of zinc, lead and copper respectively due to free minerals in each sample and performing a materials balance analysis using the MATBAL 2 program. In this balancing step the weight per cent of material at each sample point was fixed to the values in the top line of Table 2, thus the weight per cent of each element due to free mineral grains was forced to adjust. Most of the adjustments were less than 15% of the amount analysed, although one was 36%. This suggests that the error of analysis for mineral liberations is $\pm 15\%$ of the amount analysed. The weight per cent of free sphalerite observed in the samples for the 1977 study is included for comparison. The correlation is poor for most samples, although the values are in the same order of magnitude for the

concentrates from the rougher 6, cleaner 1, and cleaner 2 and for the upgrading tails which is the zinc concentrate (Table 3).

The recoveries of the free and unliberated sphalerite, galena and chalcopyrite at each sample point were calculated from the weight per cent material and the balanced assay values due to free and unliberated mineral grains (Table 4) and the results were plotted in Figs. 2 and 3. Figure 2 shows that, for the 1979 suite, there was

good recovery of free sphalerite from the cleaners but poor recovery from the roughers, especially rougher 12. By contrast, for the 1977 suite, there was good recovery of free sphalerite from the roughers, but a significant loss from the first cleaner. Figure 3 shows that only very small proportions of the free and unliberated galena and chalcopyrite were recovered in the zinc concentrate. Most were lost to the circuit tails.

Fig. 2 — Histograms showing the recoveries and losses of free and unliberated sphalerite for the 1979 and 1977 suites. The last bar (ZN-C) of the recovery graphs shows the recovery in the zinc concentrate and the last bar (CIR-T) of the loss graphs shows the total loss from the circuit. R12-F and R6-F are the amounts in the rougher 12 and 6 feeds and R12-C and R6-C are the recoveries from the respective roughers; R12-T and R6-T are losses from the rougher to the tails. CL1-F is the amount in the cleaner circuit feed and CL2 and up are either recoveries or losses from the 1st and 2nd cleaners and upgrading cells respectively. The total amount of free plus unliberated sphalerite in the circuit is 100%.

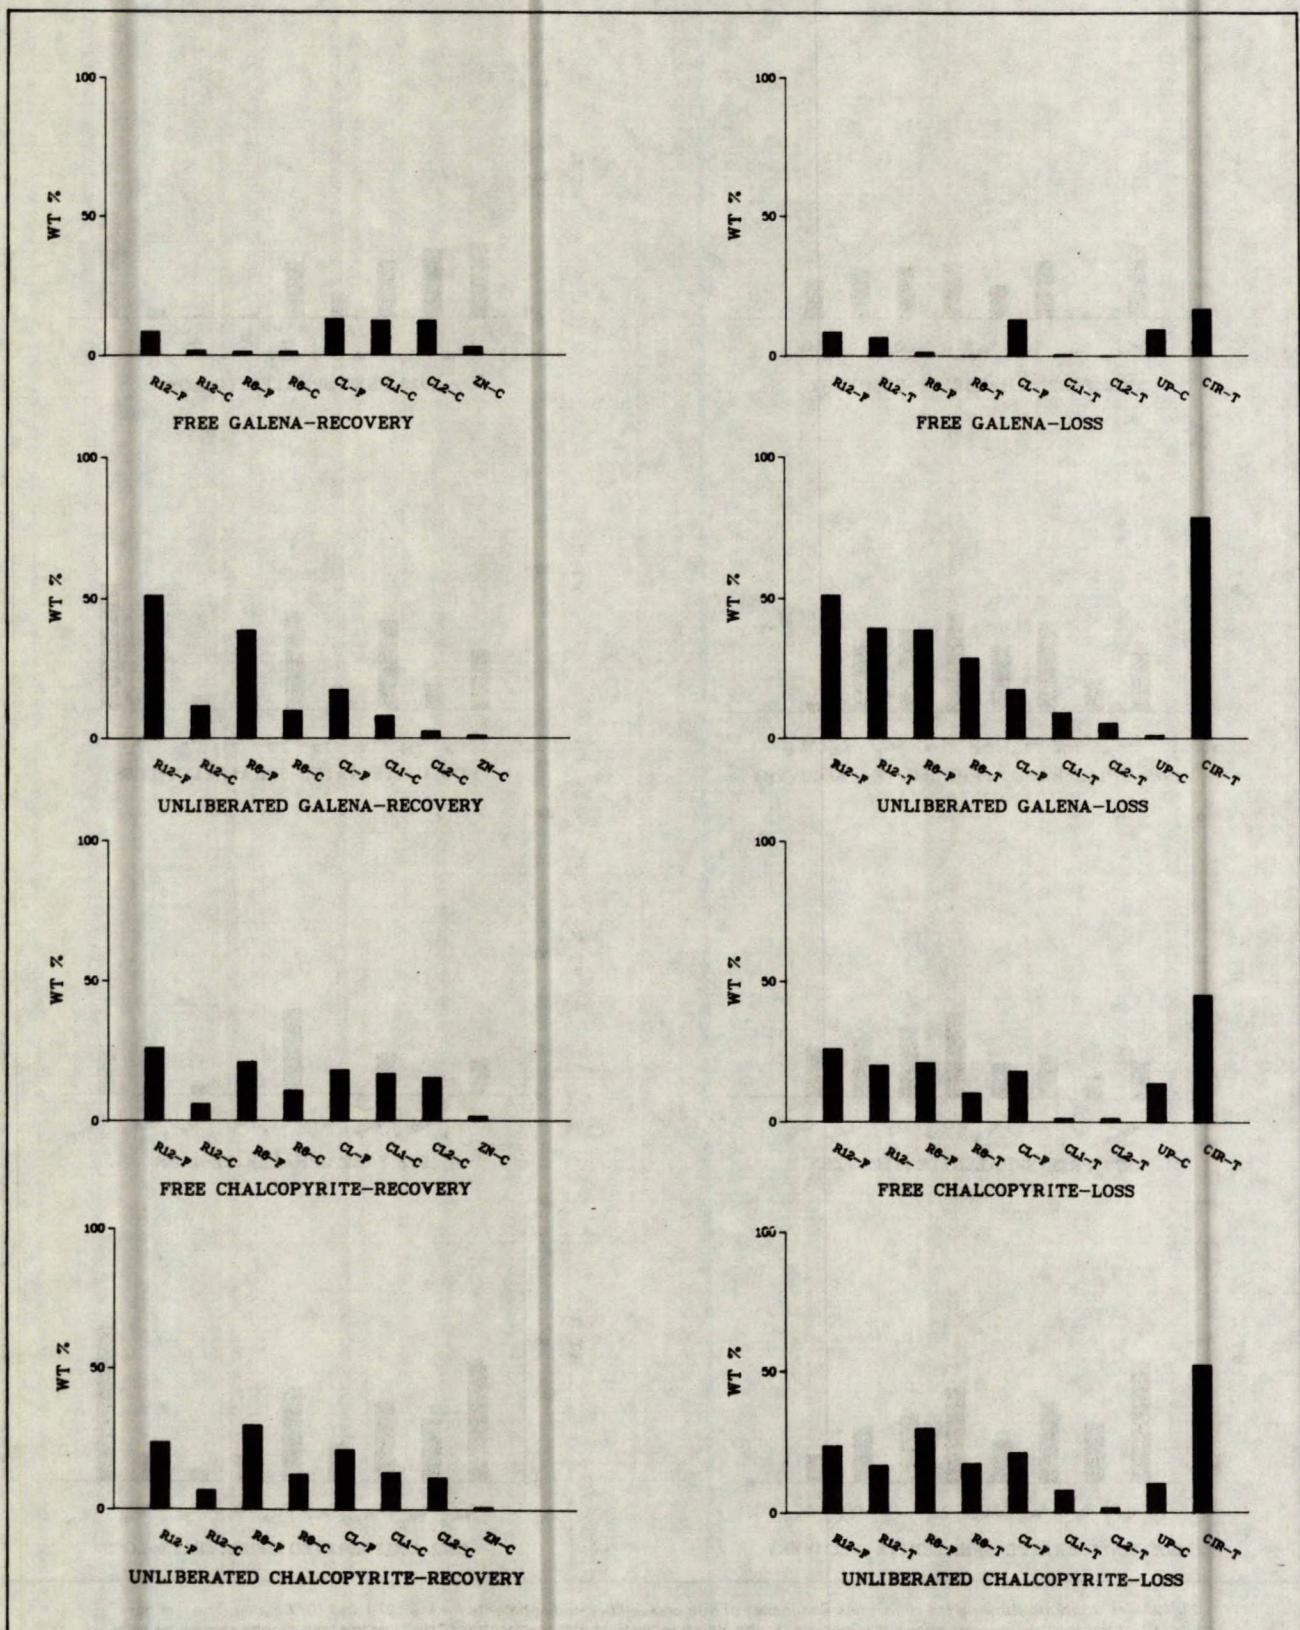

Fig. 3 — Histograms showing the recoveries and losses of free and unliberated galena and chalcopyrite for the 1979 suite. The last bar (Zn-C) of the recovery graphs shows the recovery in the zinc concentrate; the last bar (CIR-T) of the loss graphs shows the total loss from the circuit. Total amount of free plus unliberated mineral in circuit is 100%.

SIZE DISTRIBUTIONS

The size distributions of the free and unliberated grains were determined with the image analyser, and the values were adjusted to a materials balance using the same procedure as for the mineral liberations. The results are given in Tables 5 to 10 and in Figs. 4 to 9. Size distributions from the 1977 study for the zinc concentrate (upgrading tails) and for the combined mill or circuit tails (12 rougher tails + 6 rougher tails + 1st cleaner tails + upgrading concentrate) are included. It is noted that all the free and unliberated grains in the 1977 samples were finer-grained than in the 1979 samples. The relationship between the size of unliberated grains in the zinc concentrate and in the combined mill tailings (Figs. 5-7), however, was the same in both the 1979 and 1977 samples. Unliberated sphalerite, unliberated galena, and unliberated chalcopyrite grains in the zinc concentrate are coarser-grained than in the combined mill tailings; the free chalcopyrite in the combined mill tailings in both the 1977 and 1979 samples is coarse-grained; and the free galena grains in the zinc concentrates are coarser-grained than in the tailings.

The recoveries and losses of the different sized free and unliberated grains in the various cells, the zinc concentrate and the cir-

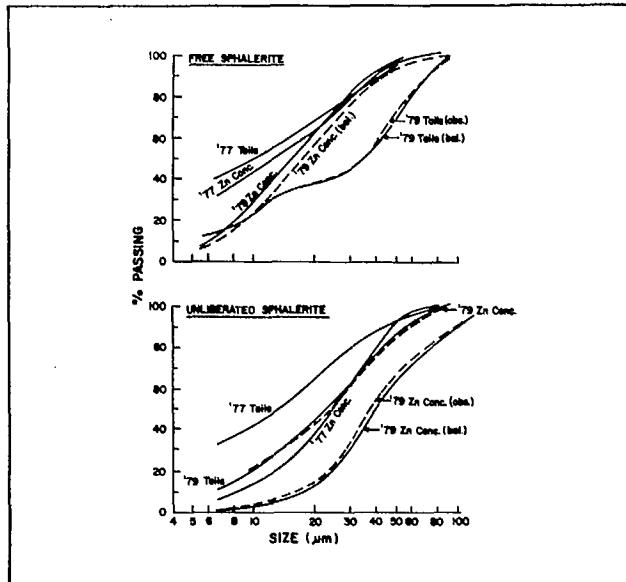

Fig. 4 — Size distributions of free and unliberated sphalerite in tails and zinc concentrates. Plotted as cumulative per cent passing.

cuit tails were calculated using the size distributions of Tables 5 to 10 and recoveries of Table 3. The results are given in Tables 11-13 and are plotted as histograms in Figs. 10-15.

Fig. 5 — Size distributions of free and unliberated galena in tails and zinc concentrates. Plotted as cumulative per cent passing.

Fig. 6 — Size distributions of free and unliberated chalcopyrite in tails and zinc concentrates. Plotted as cumulative per cent passing.

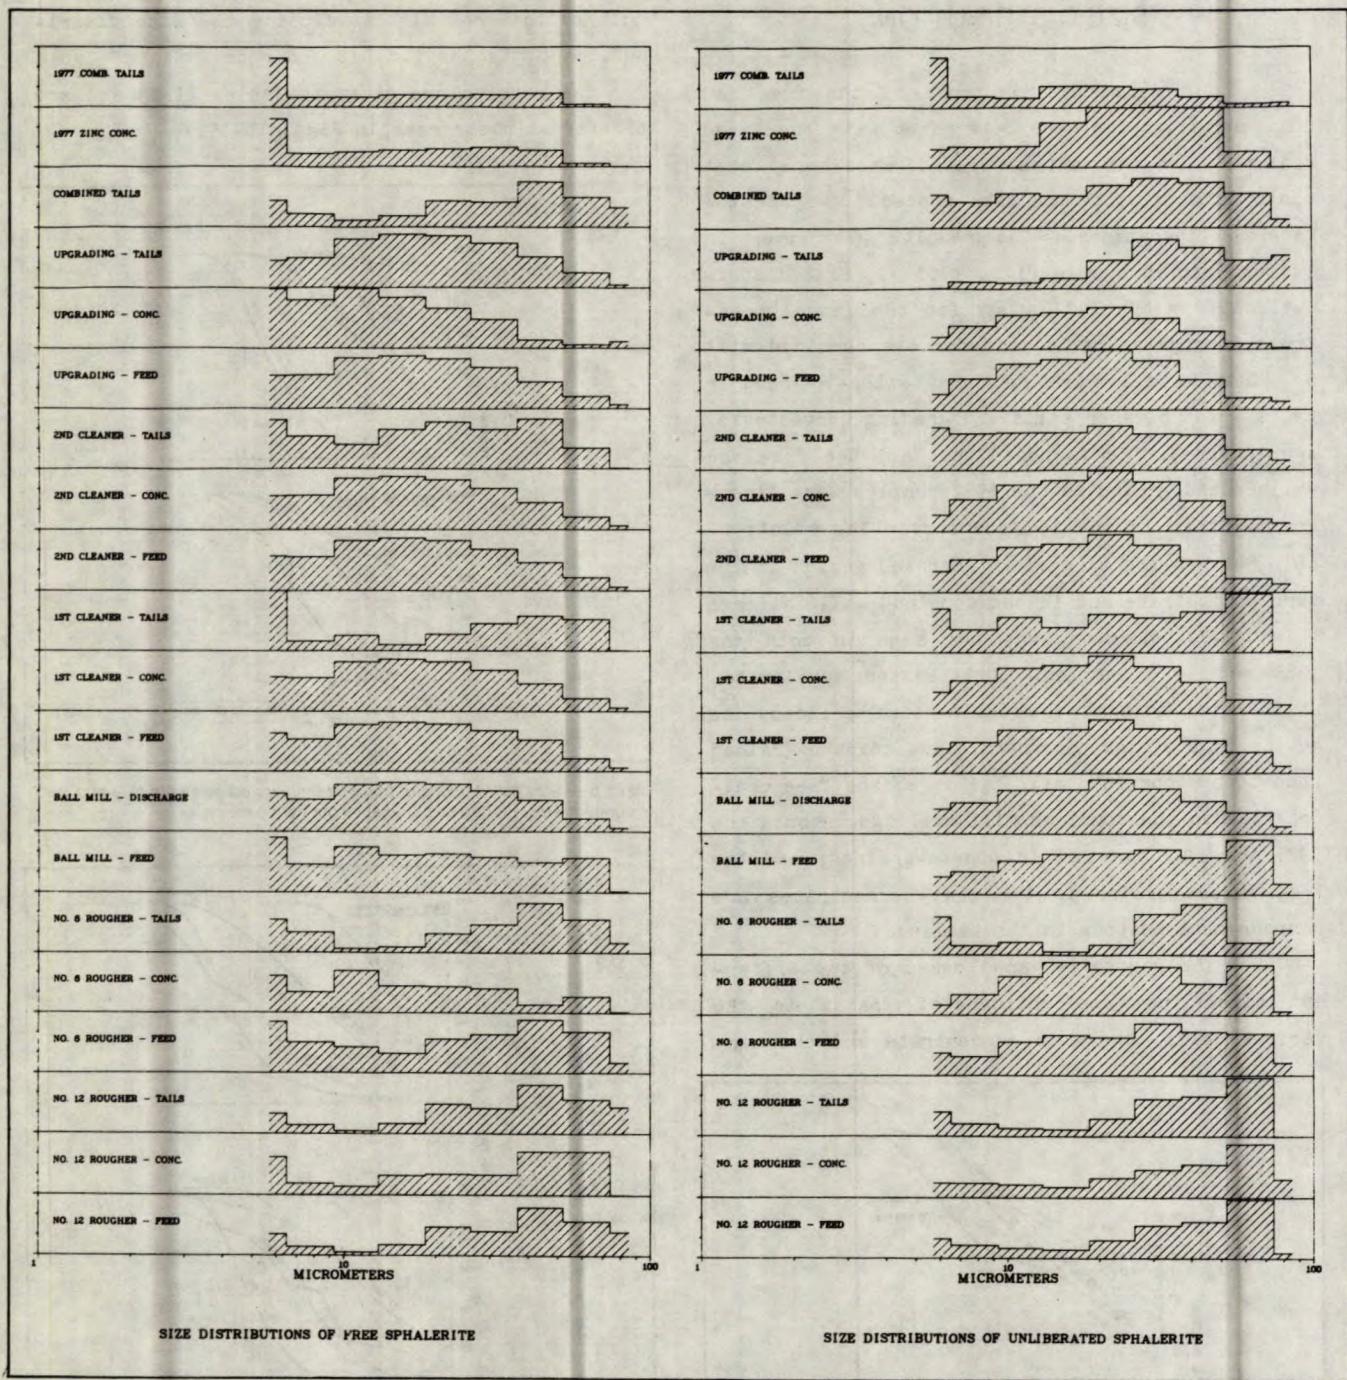

Fig. 7 — Size distributions of free and unliberated sphalerite in products.

Plotted as relative quantities of mineral in each size range of the Tyler series, i.e., $\sqrt{2}$.

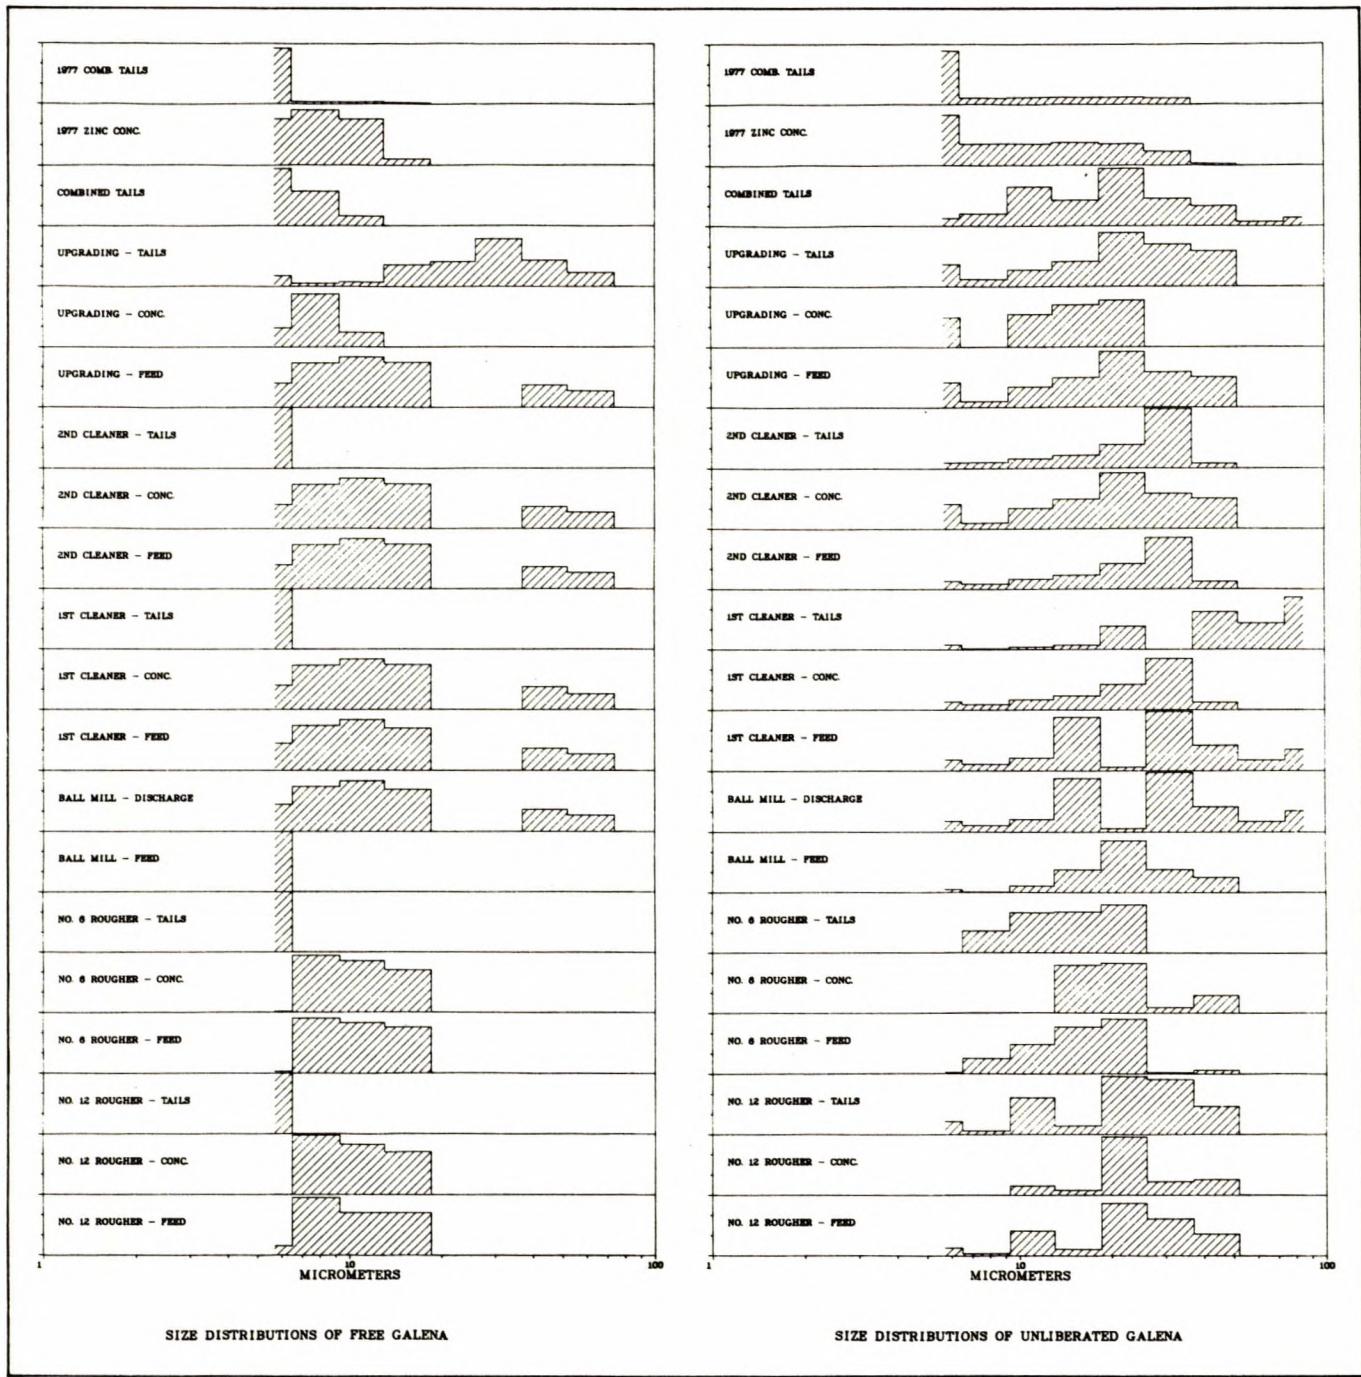

Fig. 8 — *Size distributions of free and unliberated galena in products.*

Plotted as relative quantities of mineral in each size range of the Tyler mesh series, i.e., $\sqrt{2}$.

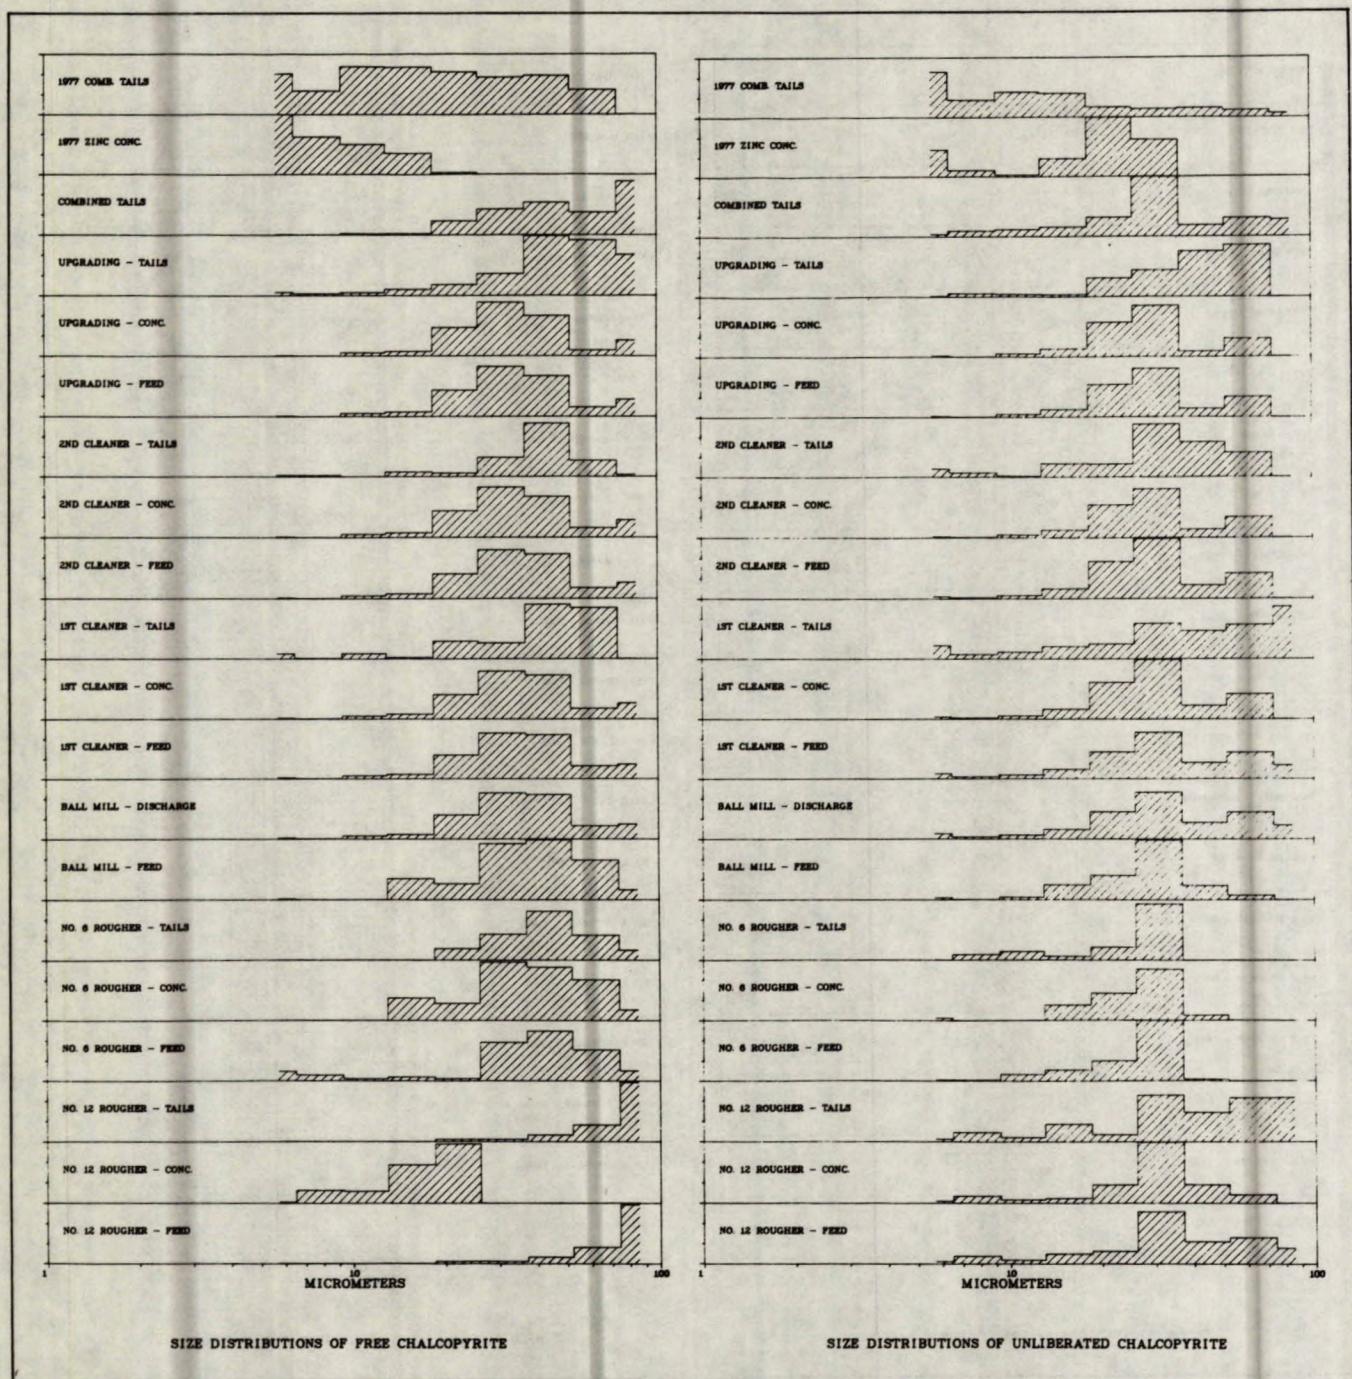

Fig. 9 — Size distributions of free and unliberated chalcopyrite in products.

Plotted as relative quantities of mineral in each size range of the Tyler mesh series, i.e., $\sqrt{2}$.

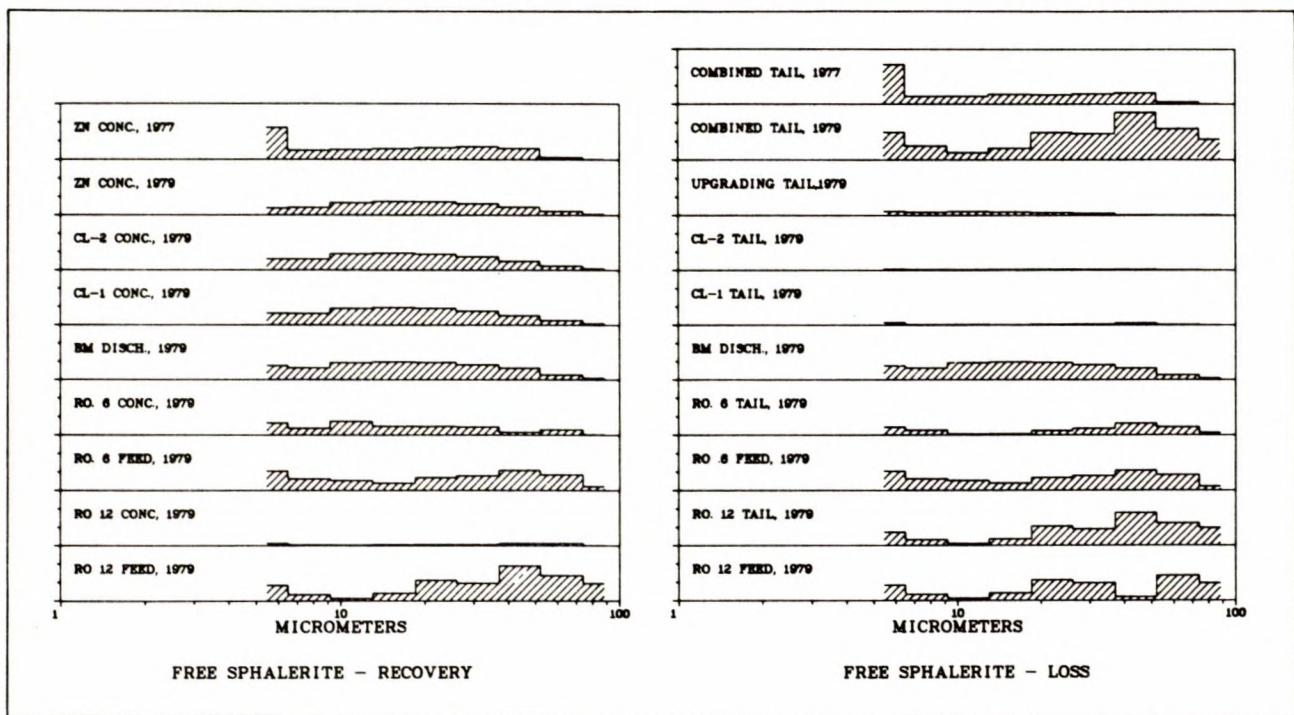

Fig. 10 — Quantities of sized free sphalerite grains recovered and lost from rougher 12, rougher 6 and cleaner cells (BM'Disch = cleaner circuit feed), and recovered and lost in zinc concentrate and circuit tails (combined tail) respectively. Data for 1977 are included for comparison. Vertical scale = 0 to 10%.

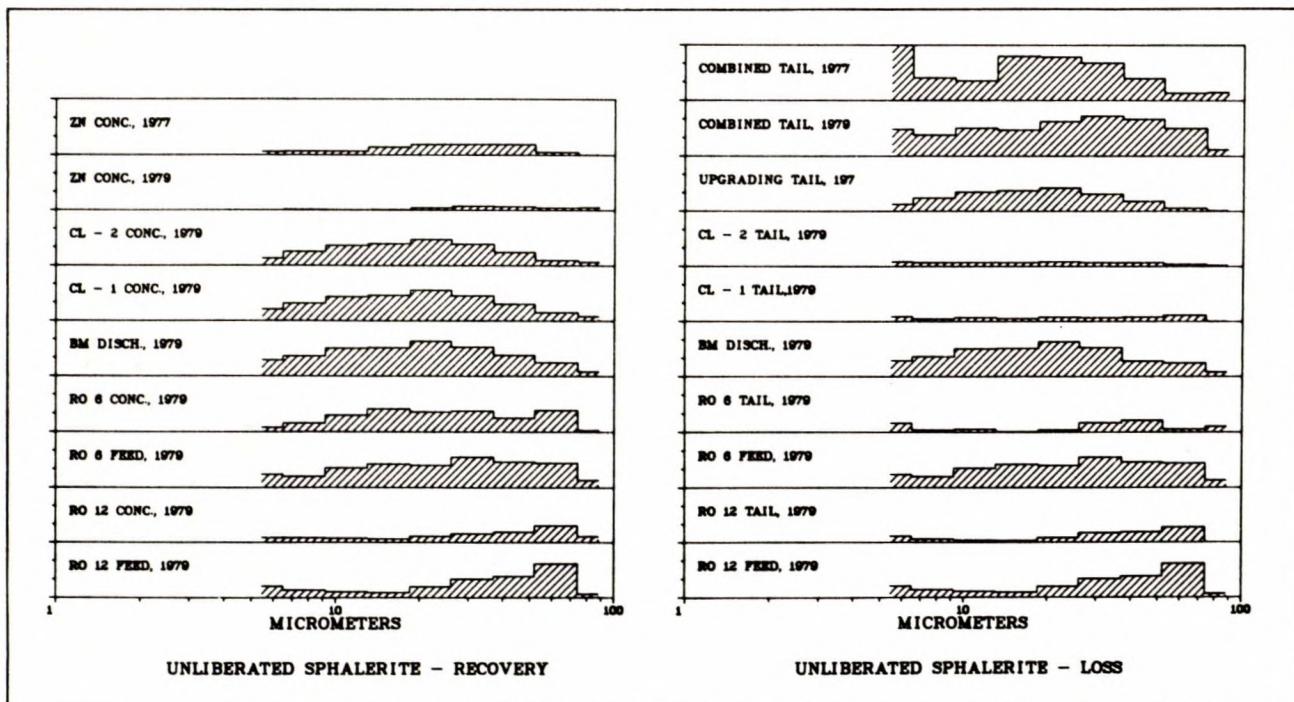

Fig. 11 — Quantities of sized unliberated sphalerite grains (size of sphalerite in middling particle) recovered and lost, as in caption to Fig. 10. Vertical scale = 0 to 10%.

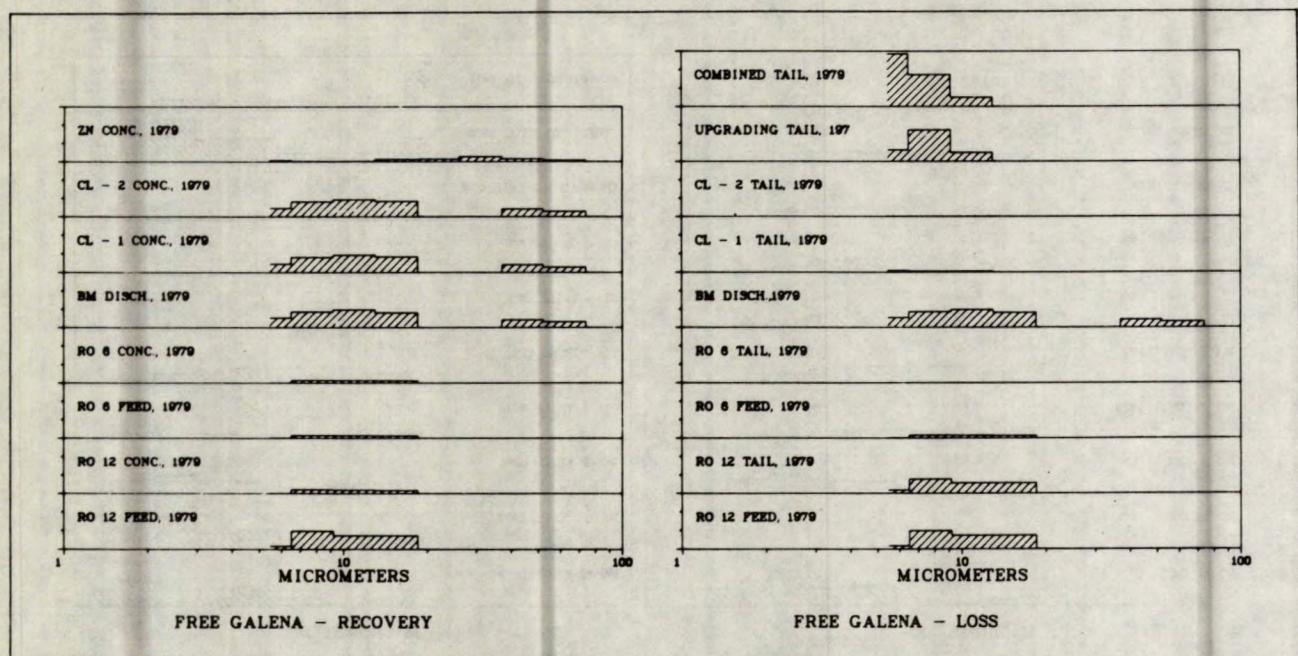

Fig. 12 — Quantities of sized free galena grains recovered and lost, as in caption to Fig. 10. Vertical scale = 0 to 10%.

Fig. 13 — Quantities of sized unliberated galena grains (size of galena in middling particles) recovered and lost, as in caption to Fig. 10. Vertical scale = 0 to 10%.

Fig. 14 — Quantities of sized free chalcopyrite grains recovered and lost, as in caption to Fig. 10. Vertical scale = 0 to 10%.

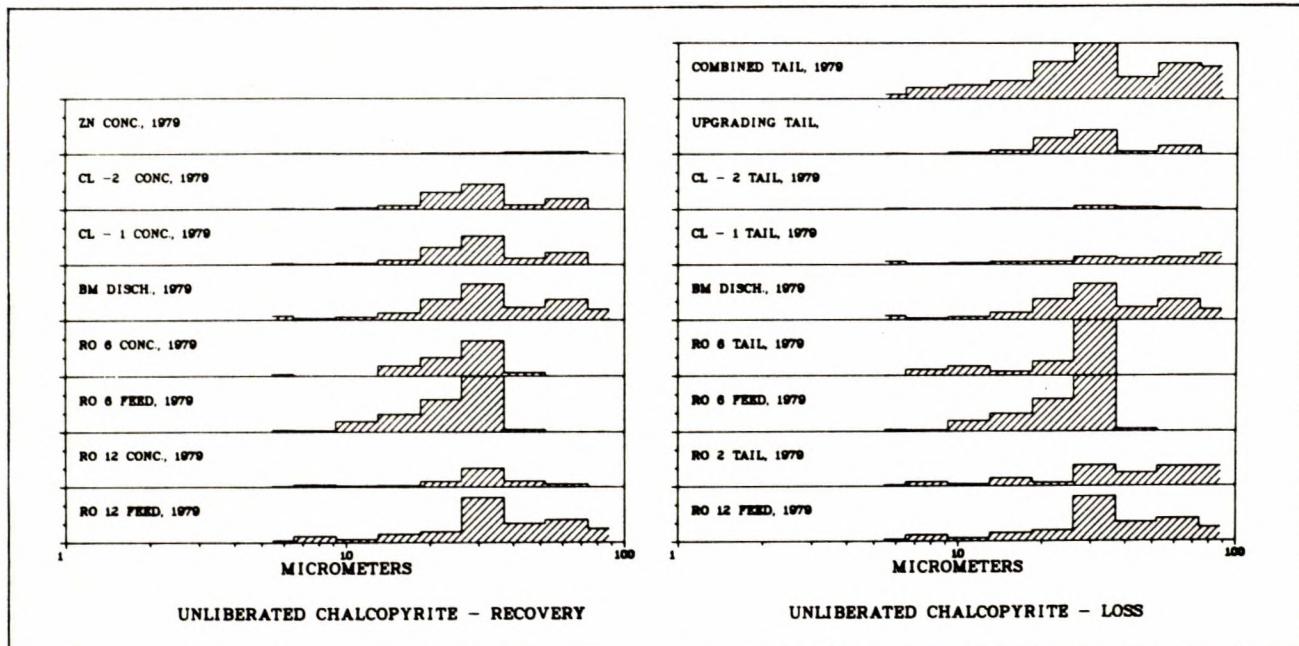

Fig. 15 — Quantities of sized unliberated chalcopyrite grains (size of chalcopyrite in middling particles) recovered and lost, as in caption to Fig. 10. Vertical scale = 0 to 10%.

* Total free plus unliberated chalcopyrite in rougher 12 plus rougher 6 = 100%

** Upgrading of tail = zinc concentrate

*** Size of unliberated chalcopyrite is size of chalcopyrite inclusions in larger middling particles

DISCUSSION

A comparison between the 1979 and 1977 samples shows several differences in the behaviour of sphalerite in the secondary zinc circuit. The main problem observed in the 1977 operation was a loss of free sphalerite to the first cleaner tailings (Table 4). This loss was reduced in the 1979 operation to 1.4 wt % of the zinc from 6.2 wt %. On the other hand, in the 1979 operation there was a higher loss of free sphalerite to the rougher tailings than in 1977 (24.5% vs 5.3% for No. 12 rougher cell and 8.6 vs 2.7% for the No. 6 rougher cell). The grain size analysis (Figs. 10 and 11) shows that the free sphalerite grains in the rougher cells are large enough to be recovered. This suggests that, periodically, parts of the concentrator do not operate efficiently. It is proposed that fluctuations in the operation of the rougher cells in the secondary zinc circuit could be reduced to a minimum by monitoring the zinc content of the rougher tailings and keeping the value around 0.9 wt % Zn which is the value obtained in the 1977 operation.

The grade of the zinc concentrate from the 1979 operation was much higher than from the 1977 operation (53.5 vs 40.5 wt % Zn), but the recovery was lower (17.3 vs 27.4% of the zinc in the secondary zinc circuit). The higher grade zinc concentrate was achieved by discarding more of the unliberated sphalerite (7% of the total unliberated sphalerite in the circuit was recovered in zinc concentrate versus 15% in 1977), but there was also a high loss of free sphalerite (35% of the total free sphalerite in the circuit was recovered in zinc concentrate versus 50% in 1977).

Most of the galena in the circuit (80 wt %) is in middling grains and nearly all of it (79 wt %) is lost to the tailings. The free galena is very fine-grained and most of it (17 wt % of galena) is also lost to the tailings (Fig.

13). A small amount of free galena (3.0 wt % of galena in the circuit), and of galena attached to sphalerite (1.5 wt % of galena in the circuit) is recovered in the zinc concentrate.

A significant amount of the chalcopyrite (47 wt %) in the circuit is free and most of it (45 wt %) is discharged to the tailings. Much of this free chalcopyrite is in grains larger than 37 μm in size. In the 1977 samples a significant proportion of the chalcopyrite in the tailings was also in large free grains. The unliberated chalcopyrite grains are also discharged to the mill tailings. Some of the unliberated grains are large enough to be liberated by regrinding.

ACKNOWLEDGEMENTS

The authors thank R. Grant of BMS for supplying the samples and chemical analyses, and J.M.D. Wilson of the Ore Processing Laboratory for consultations and guidance in using the MATBAL 2 program.

OPINION POLL

The opinion of concerned readers may influence the direction of future CANMET research.

We invite your assessment of this report - No.

Is it useful? Yes _____ No _____

Is it pertinent to an industry problem? Yes _____ No _____

Is the subject of high priority? Yes _____ No _____
