# A New Deconvolution Method for Analysis of Probability Density Distribution Spectra Observed in Gamma-Ray Interrogation Measurements of Multi-Phase Flows 

D.D.S. Liu*

#### Abstract

A numerical method for the deconvolution of probability density distribution spectra (PDDS) has been developed. It is based on principles of the least square and the Newton-Raphson iteration algorithm. The PDDS were obtained from measurements of multi-phase flows using a gamma-ray interrogation technique developed recently in the Synthetic Fuels Research Laboratory of the Energy Research Laboratories, CANMET in collaboration with the Chalk River Nuclear Laboratories, Atomic Energy of Canada Limited. The deconvoluted PDDS contain information on the hydrodynamic parameters of multi-phase flow phenomena. Fundamental equations for the numerical method were translated into a Fortran program for practical applications. Examples of PDDS deconvolutions for both simulated and observed spectra are given.

# Nouvelle méthode de déconvolution pour l'analyse des spectres de distribution de la densité de probabilité obtenus lors de mesures d'interrogation aux rayons gamma d'écoulements multiphases 

D.D.S. Liu*

## Résumé

Une méthode numérique de déconvolution des spectres de distribution de la densité de probabilité (SDDP) a été élaborée. Elle est basée sur les principes des moindres carrés et sur l'algorithme d'itération de Newton-Raphson. Les SDDP ont été obtenus lors de mesures d'écoulements multiphases basées sur une technique d'interrogation aux rayons gamma récemment mise au point au Laboratoire de recherche sur les combustibles synthétiques des Laboratoires de recherche sur l'énergie (CANMET), en collaboration avec les laboratoires nucléaires de Chalk River d'Energie atomique du Canada, Limitée. La déconvolution des SDDP fournit des renseignements sur les paramètres hydrodynamiques des phénomènes d'écoulement multiphase.
Un programme Fortran contenant les équations fondamentales utilisées dans la méthode numérique a été écrit en vue d'applications pratiques. Des exemples de déconvolution de SDDP simulés et observés sont donnés.

## INTRODUCTION

Bubble columns are widely used as absorbers, catalytic slurry reactors, and bioreactors (1-5). Although easy to use, bubble columns are difficult to design because their multi-phase flow characteristics are complex. Hydrodynamic studies of multi-phase flows at low temperatures and pressures can be easily carried out using instruments described in the literature (6-9). At high temperatures and pressures, however, difficulties occur because the instruments cannot be immersed suitably in the flow, creating a need for signals which can penetrate the thick reactor walls.

The gamma-ray interrogation method, developed by CANMET in collaboration with the Atomic Energy of Canada Limited's Chalk River Nuclear Laboratories (AECL-CRNL), offers an excellent option (10). No insertion of probes is required.

The principle of gamma-ray interrogation technique for multi-phase flow measurements and statistical methods for data analyses was described previously (10). It shows that the probability density distribution spectra (PDDS) can be used to derive information on factors such as time-averaged holdups, homogeneity of flow fields, bubble size distributions, and flow regimes.

Because of the random emission of photons from a radioisotope, the detected signal fluctuates randomly about a mean value. In a homogeneous flow field, the observed PDDS would be a Poisson distribution with a natural standard deviation (Fig. 1). In this case, the mean counting rate is directly related to the mean path length of gamma-rays passing through the material being measured.
However, in most measurements of multi-phase flow carried out in the present work, the PDDS appear highly asymmetrical (Figs. 2 to 4). Accordingly, not only is the mean counting rate important, but also the shape of the PDD spectrum including major peaks and shoulders must be considered in order to obtain information on hydrodynamic behaviour (11).

To obtain detailed information, a statistical model was developed (11). It involves the deconvolution of PDDS. A numerical method for deconvolution of PDDS for use in analyzing the hydrodynamic behaviour with the model is described.

## THEORY

## Convolution and Deconvolution

Consider the measurement of a quantity $\mathrm{T}(\mathrm{x})$ using a linear system characterized by a response function $R(x, u)$. The relation between the measured signal, $M(u)$, and the true signal, $T(x)$, may be represented as:

$$
\begin{equation*}
M(u)=\int_{0}^{\infty} R(x, u)^{*} T(x)^{*} d x+N(u) \tag{Eq 1}
\end{equation*}
$$

where:

$$
\begin{aligned}
\mathrm{N}(\mathrm{u})= & \text { random noise inherent in the sys- } \\
& \text { tem being measured } \\
\mathrm{u}= & \text { variable transformed from } \times \text { by } \\
& \text { the convolution } \\
\mathrm{x} \quad= & \text { variable of the true signal. }
\end{aligned}
$$

When systems exhibit translational invariance, the response function takes the form $R(x-u)$ and Equation 1 becomes:

$$
\begin{equation*}
M(u)=\int_{0}^{\infty} R(x-u)^{*} T(x)^{*} d x+N(u) \tag{Eq 2}
\end{equation*}
$$

Equations 1 and 2 are commonly referred to as the convolution integral (12).

For discrete spectra, such as the gamma-ray interrogation spectrum considered here, the random noise $N(u)$ can be suppressed to a much smaller value than the integral. Therefore, the neglect of $N(u)$ in Equation 1 or 2 may not introduce significant error.

Obviously, the task of data analysis is to obtain the true signal, $T(x)$, from the measured numbers of $M(u)$. Procedures to solve Equation 2 are referred to as deconvolutions (13).

## Problem

A PDD spectrum is a plot of the number of occurrences versus counting rates (counts/sampling time). Examples are given in Figures 1 to 5 . The PDD spectrum for an unperturbed system, such as the spectrum measured in a homogeneous flow field, has a Poisson distribution which is equivalent to a Gaussian distribution when the counting rate is high:

$$
Y(N)=H^{*} \exp \left[-(N-C)^{2} /\left(2^{*} \sigma^{2}\right)\right]
$$

where:
C = counting rate at the peak centre
H = peak height
$\mathrm{N}=$ counting rate [or alternatively, the channel number]
$\sigma=$ standard deviation
$Y(N)=$ height at counting rate $N$.
For a multi-phase flow, the measured PDD spectrum is, in principle, the convolution of many Poisson spectra in which the peak heights and centre positions may be different from one another. This is caused by the fact that under a given set of conditions, the bubble sizes and the shapes of individual bubbles are different. Each Gaussian sub-peak represents the fraction of time (over the sum of all the peaks) in which a particular hydrodynamic phenomenon, (e.g., local holdup) is observed. This is typical for bubble columns in which the hydrodynamic fluctuates with time. The whole PDD spectrum can be written as:

$$
\begin{equation*}
Y(N)=\sum_{i=1}^{m}\left\{H _ { i } { } ^ { * } \operatorname { e x p } \left[-\left(N-C_{i}\right)^{\left.\left.2 /\left(2^{*} \sigma_{i}^{2}\right)\right]\right\}}\right.\right. \tag{Eq 4}
\end{equation*}
$$

where:
$\mathrm{C}_{\mathrm{i}} \quad=$ counting rate for the centre of the ith peak
m = number of Gaussian sub-peaks convoluting the spectrum and subscript i represents the i subpeak.

Equation 4 is similar to an equation describing a digital recording of an ordinary nuclear spectrum (14), except that in the latter, energy or frequency characterized by the material is used for the abscissa and photon density is the ordinate.

The problem is to find an optimal number of peaks, $m$, which is equal to the actual number of peaks ( $M$ ) and value of $H_{i}$ and $C_{i}$ with $i=1$ to $m$ such that values of $Y(N)$ for $\mathrm{N}=0$ to $\propto$ calculated from Equation 2 are the best representation of $\mathrm{Y}(\mathrm{N})$ observed in measurements. All of these parameters are independent variables.

A comparison of Equation 4 with the generalized Equation 2 shows the following equivalences in operators and parameters between the two cases:

$$
\begin{aligned}
& \mathrm{x}<====>\mathrm{N} \\
& \mathrm{u}<=====>\mathrm{C}_{\mathrm{i}} \\
& \mathrm{M}(\mathrm{x})<====>\mathrm{Y}(\mathrm{~N}) \\
& \mathrm{T}(\mathrm{u})<====>\mathrm{H}\left(\mathrm{C}_{\mathrm{i}}\right) \\
& \mathrm{R}(\mathrm{x}, \mathrm{u})<====>\exp \left[-\left(\mathrm{N}-\mathrm{C}_{\mathrm{i}}\right)^{2} /\left(2^{*} \sigma_{\mathrm{i}} 2\right)\right] \\
& \mathrm{du}<====>1 \\
& \infty<====>\sum_{i}\left(\delta\left(C_{i}\right)\right)^{*}
\end{aligned}
$$

where:

$$
\begin{aligned}
<====> & =\text { corresponds to } \\
\delta\left(\mathrm{C}_{\mathrm{i}}\right) & =\text { a unit-sampling function. }
\end{aligned}
$$

These equivalences show that Equation 4 can be cast in the generalized form of Equation 2. Therefore, we have a typical deconvolution problem.

## Theoretical Description

The least-square fitting technique is one of the best methods for determining parameters when the experimental results contain deviations and this technique is used here (15).

Let us define a set of values $\left[H_{i},{ }_{F}, \mathrm{C}_{\mathrm{i}} \mathrm{F}^{2}(\mathrm{~N})\right]$ where $\mathrm{i}=1$ to M that represent the final least-squared parameters, where F indicates final fitted values. Similarly, O and C indicate observed and calculated values in the iteration procedures.

According to the least-square principle (15), the problem is to find $\left[H_{i}{ }^{F}, C_{i}{ }^{F}\left(N_{i}\right)\right]$ so that:

$$
S=\sum_{N=0}^{\infty}[Y O(N)-Y F(N)]^{2}=\text { minimum }
$$

Eq 5

The Newton-Raphson iteration method was used to solve Equation 5 (15-17). This method involves the linearization of non-linear equations, e.g., Equation 2 or 3, by the Taylor series. This particular method requires initial values of parameters for iteration. Once reasonable initial values have been estimated, in any step of iteration, the "calculated" parameters are always regenerated. The parameters during iterations are assumed to be $\left[H_{i}{ }^{\mathrm{C}}, \mathrm{C}_{1}{ }^{\mathrm{C}}\right]$ where $\mathrm{i}=1$ to m and $\mathrm{m}>\mathrm{M}$.
The Taylor series gives:

$$
\begin{aligned}
Y F(N) & =Y C(N)+\sum_{i=1}^{m}\left(\partial Y C(N) / \partial \Delta H_{i}\right) * \Delta H_{i} \\
& +\sum_{i=1}^{m}\left(\partial Y C(N) / \partial \Delta C_{i}\right) * \Delta C_{i} \\
& +O\left(\Delta H_{i}^{2}, \Delta C_{i}^{2}\right)
\end{aligned}
$$

where:

$$
\begin{array}{ll}
\Delta \mathrm{C}_{\mathrm{i}}=\mathrm{C}_{\mathrm{i}} \mathrm{~F}-\mathrm{C}_{\mathrm{i}} \mathrm{C} & \mathrm{Eq} 7 \\
\Delta \mathrm{H}_{\mathrm{i}}=\mathrm{H}_{\mathrm{i}} \mathrm{~F}-\mathrm{H}_{\mathrm{i}}^{\mathrm{C}} & \mathrm{Eq} 8
\end{array}
$$

$O(X)=$ sum of all terms with order higher than, or equal to, 2.
Inserting Equation 6 into Equation 5, neglecting higherorder terms, yields:

$$
\begin{aligned}
S & =\sum_{N=0}^{\infty}\left[Y O(N)-Y C(N)-\sum_{i=1}^{m}\left\{\partial Y C(N) / \partial \Delta H_{i}\right\}^{*} \Delta H_{i}\right. \\
& \left.-\sum_{i=1}^{m}\left\{\partial Y C(N) / \partial \Delta C_{i}\right\}^{*} \Delta C_{i}\right]^{2}=\text { minimum } \quad E q
\end{aligned}
$$

This equation holds only when $\Delta H_{i}$ and $\triangle C_{i}$ are small. Otherwise, higher-order corrections must be made.
Conditions for Equation 9 are:

$$
\begin{equation*}
\partial \mathrm{S} / \partial \mathrm{H}_{\mathrm{j}}=0 \text { where } \mathrm{j}=1 \text { to } \mathrm{m} \tag{Eq 10}
\end{equation*}
$$

and

$$
\partial \mathrm{S} / \partial \mathrm{C}_{\mathrm{j}}=0 \text { where } \mathrm{j}=1 \text { to } \mathrm{m}
$$

Eq 11
From Equation 9 to 11:

$$
\begin{gathered}
\partial S / \partial H_{j} \sim 2 * \sum_{N=0}^{\sum}\left\{\left[\mathrm{OMC}(\mathrm{~N})-\sum_{\mathrm{i}=1}^{\mathrm{N}}\left(\partial \mathrm{YC}(\mathrm{~N}) / \partial \Delta \mathrm{H}_{\mathrm{i}}\right) * \Delta \mathrm{H}_{\mathrm{i}}\right.\right. \\
\left.-\sum_{\mathrm{i}=1}^{\mathrm{m}}\left(\partial \mathrm{YC}(\mathrm{~N}) / \partial \Delta \mathrm{C}_{\mathrm{i}}\right) * \Delta \mathrm{C}_{\mathrm{i}}\right] *\left[\partial \mathrm{YC}(\mathrm{~N}) / \partial \Delta \mathrm{H}_{\mathrm{j}}\right\}=0
\end{gathered}
$$

Eq 12

$$
\partial S / \partial \Delta C_{i} \sim 2 * \sum_{N=0}^{\infty}\left\{\left[O M C(N)-\sum_{i=1}^{m}\left(\partial Y C(N) / \partial \Delta H_{i}^{C}\right) * \Delta H_{i}\right.\right.
$$

$$
\begin{equation*}
\left.\left.-\sum_{i=1}^{m}\left(\partial Y_{C}(N) / \partial \Delta C_{i}\right) * \Delta C_{i}\right]^{*}\left[\partial Y \mathrm{C}(N) / \partial \Delta C_{j}\right]\right\}=0 \tag{Eq 13}
\end{equation*}
$$

where:

$$
O M C(N)=Y O(N)-Y C(N)
$$

Eq 14
Note that $\mathrm{H}_{\mathrm{i}}{ }^{\mathrm{F}}$ and $\mathrm{C}_{\mathrm{i}}{ }^{\mathrm{F}}$ are constants for $\mathrm{i}=1$ to M and $\mathrm{H}_{\mathrm{i}}{ }^{\mathrm{F}}$ vanishes for $i=M+1$ to m .
Since $C_{i}{ }^{F}$ and $H_{i}{ }^{F}$ are constants, according to Equation 7 and 8 , the following relations hold:
$\partial \mathrm{YC}^{\mathrm{C}}(\mathrm{N}) / \partial \Delta \mathrm{H}_{\mathrm{i}}=-\partial \mathrm{YC}^{\mathrm{C}}(\mathrm{N}) / \partial \mathrm{H}_{\mathrm{i}}^{\mathrm{C}}$
Eq 15
$\partial Y^{C}(N) / \partial \Delta C_{i}=-\partial Y^{C}(N) / \partial C_{i}^{C}$
Eq 16

Inserting Equations 15 and 16 into Equations 12 and 13 results in:

$$
\begin{align*}
& \sum_{N=0}^{\infty}\left\{A(N)^{*}\left[\partial Y C(N) / \partial \Delta H_{j}\right]\right\}=0 \text { for } j=1 \text { to } \mathrm{m}  \tag{Eq 17}\\
& \sum_{N=0}^{\infty}\left\{A(N)^{*}\left[\partial Y C(N) / \partial \triangle C_{j}\right]\right\}=0 \text { for } j=1 \text { to } \mathrm{m}
\end{align*}
$$

where:

$$
\begin{aligned}
A(N) & =\left[O M C(N)+\sum_{i=1}^{m}\left\{\partial Y C(N) / \partial \Delta H_{i}^{C}+{ }^{*} \Delta H_{i}\right.\right. \\
& \left.+\sum_{i=1}^{m}\left\{\partial Y^{C}(N) / \partial \Delta C_{i} C^{*} \Delta C_{i}\right\}\right]
\end{aligned}
$$

Eq 19
and from Equations 3,15 , and 16 :

$$
\partial Y^{C}(N) / \partial \Delta H_{i}^{C}=\exp \left[-\left(N-C_{i}^{C}\right)^{2} /\left(2^{*} \sigma_{i}^{2}\right)\right] \quad \text { Eq } 20
$$

$$
\begin{align*}
& \partial Y \mathrm{C}(N) / \partial \Delta \mathrm{C}_{\mathrm{i}}^{\mathrm{C}}=\left[\left(\mathrm{N}-\mathrm{C}_{\mathrm{i}}^{\mathrm{C}}\right)^{*} H_{i} / \sigma_{i}^{2}\right] \\
& \quad * \exp \left[-\left(N-C_{i}\right)^{2} /\left(2^{*} \sigma_{i}^{2}\right)\right] \tag{Eq 21}
\end{align*}
$$

Equations 17 and 18 provide 2 m linear equations for 2 m unknowns, $\left(\triangle \mathrm{H}_{\mathrm{j}}, \triangle \mathrm{C}_{\mathrm{j}}\right)$ with $\mathrm{j}=1$ to m . Although $m>M$, the iteration (see below) will eliminate the extra $m-M$ peaks, originally assumed at the beginning of iteration.

## Iteration Procedure

To solve the problem, the following procedure, based on the theory developed in the previous section, can be used:

1. Estimate a set of $\left(\mathrm{H}_{\mathrm{i}}{ }^{\mathrm{C}}, \mathrm{C}_{\mathrm{i}}{ }^{\mathrm{C}}\right)$ values for $\mathrm{i}=1$ to m with $\mathrm{m}>\mathrm{M}$, where M is still unknown. (However, the choice of $m$ can be easily made by the procedure described later.)
2. Calculate the $\sigma_{i}$ for $i=1$ to $m$, according to the calibration from experiments, or from the theory described earlier (18).
3. Calculate values of $\mathrm{Y}^{\mathrm{C}}(\mathrm{N})$, according to Equation 4 for the range of N observed. These allow the calculation of $\mathrm{OMC}(\mathrm{N})$ defined in Equation 14.
4. Formulate 2 m linear equations according to Equations 17 and 18 with the assistance of Equations 19 to 21.
5. Solve the 2 m linear equations to obtain the variables $\left(\triangle H_{i}, \triangle C_{i}\right)$ for $i=1$ to m .
6. Calculate the new parameters $\left(H_{i} C, C_{i} C\right)$ for $i=1$ to $m$, according to the following equations analogous to Equations 7 and 8:

$$
\begin{align*}
& H_{i}=H_{i} \mathrm{C}+\Delta H_{i} \mathrm{c}  \tag{Eq 22}\\
& \mathrm{C}_{\mathrm{i}}=\mathrm{C}_{\mathrm{i}} \mathrm{c}+\Delta \mathrm{C}_{\mathrm{i}} \mathrm{c}  \tag{Eq 23}\\
& \text { where } \mathrm{i}=1 \text { to } \mathrm{m} .
\end{align*}
$$

These values will become closer to the final fitted values if the higherorder effects are much smaller than the first-order effects described in Equation 6.
7. Assign the new parameters for next iteration by:

$$
\begin{align*}
& H_{i} C=H_{i}  \tag{Eq 24}\\
& C_{i} \mathrm{C}=C_{i} \\
& \text { for } \mathrm{i}=1 \text { to } \mathrm{m} .
\end{align*}
$$

Eq 25
8. When some of the $H_{i}{ }^{c}$ values become very small (indicating they are extra parameters originally assumed in the input) they are neglected.
9. Calculate the root mean squared deviation of fit, using the new parameters. If the deviation converges when compared with the results from the previous iteration, the calculation can be terminated.
10. Repeat Procedure 2 for the next iteration.

## Other Applications

The deconvolution method can be used for almost any type of spectroscopy where quantized discrete spectra exist. In the deconvolution of ordinary spectra (e.g., Mossbauer spectrum) the frequencies of peak centres are fixed. Therefore, known numbers of $C_{i}$ - where $i=1$ to $m(m>M)$ - can be initially assigned. The problem is then simplified to only one set of $m$ linear equations resulting from Equation 17. This is much simpler than the case considered here.
Note that in particular applications, the appropriate response function (e.g., slit function in the optical spectroscopy, or 'kernel' in the nuclear spectroscopy equivalent to that of Equation 1) must be used.

## NUMERICAL EXAMPLES

A computer program based on the procedures described above was written in Fortran-77 for a Cromemco System One computer. It has been tested to deconvolute spectra simulated by given parameters and spectra observed in two-phase flow measurements using the gamma-ray interrogation technique ( 10,11 ). Some examples are given below.
In the gamma-ray interrogation equipment, a multichannel analyzer coupled with a rate meter capable of signal suppression was used. The counting rate N is linearly proportional to the channel number. Therefore, examples of probability density distribution spectra will be expressed as number of occurrences versus channel number. Since a high counting rate system is used, the PDD spectrum for an unperturbed system is nearly a perfect Gaussian which is assumed for the response function. The instrument was calibrated using a pulse generator. It showed that the true signal was a unitsampling function, i.e., each frequency is represented by a single channel. The standard deviation of the Gaussian peaks is given by (11):

$$
\begin{equation*}
\sigma_{i}=19.3+0.00743^{*}\left(C_{i}-172\right) \tag{Eq 26}
\end{equation*}
$$

This relation was used for both simulated and observed spectra.

## Initial Estimation of Convoluting Peaks

A convoluted PDD spectrum has a full width at half maximum [FWHM] always larger than, or equal to, the theoretical FWHM of the unperturbed PDD spectrum at the same peak position. Also, the channel number of the peak maximum is always close to a peak in the convoluted spectrum. Based on this fact, the value of $\mathrm{C}_{1}{ }^{\mathrm{C}}$ can then be assigned to the position of peak maximum.

Using the peak height at maximum, the $\mathrm{C}_{1}{ }^{\mathrm{C}}$, then $\sigma_{1}$ from Equation 26, a theoretical Gaussian peak based on Equation 1 was calculated. Subtraction of the calculated Gaussian peak from the original PDDS resulted in the first differential PDD spectrum. This method is referred to as spectrum stripping. Subsequently, the differential PDD spectrum from this step was considered independently for further spectrum stripping to obtain the centre position of the next peak by the same technique. This procedure was repeated until the differential spectrum became very small. Thus, m central positions were estimated for the initial iteration.

Following the spectrum stripping, the peak positions, $\mathrm{C}_{\mathrm{i}}$, where $i=1$ to $m$, were fixed and a least-square procedure was used to obtain the initial estimated input peak heights, $\mathrm{H}_{\mathrm{i}}^{\mathrm{C}}$, where $\mathrm{i}=1$ to m . Very small or negative peaks were ignored. A new number of ( $\mathrm{H}_{\mathrm{i}}{ }^{\mathrm{C}}, \mathrm{C}_{\mathrm{i}}{ }^{\mathrm{C}}$ ) where $i=1$ to a new number $m^{\prime}$ was then obtained. We observed that the $\mathrm{m}^{\prime}$ was always larger than the final fitted number of peaks, M , thus fulfilling the requirement of the Newton-Raphson iteration method.
In the example given in Table 1, five peaks located at channels 194, 227, 269, 313 and 355, with heights of 2043.9, 261.2, 172.8, 143.3 and 11.03, respectively, were assumed. These values and Equation 26 were used in Equation 4 to construct the simulated spectrum. The simulated spectrum was then considered as observed data, $\mathrm{Y}^{\circ}(\mathrm{N})$, for deconvolution. The first section of Table 1 lists the assumed parameters. In this case, the value of $M$ is 5 . Results of the spectrum stripping are given in the second section of Table 2. This gives a value of $\mathrm{m}^{\prime}=7$, larger than $M=5$.

## Deconvolution of Simulated PDD Spectra

In this section, deconvolution of some simulated spectra is shown. The input peak positions and heights, as shown in Tables 2 to 6, were used to calculate the simulated PDDS based on Equation 4 and 26. The simulated PDDS were then deconvoluted by the procedures described above.

Table 1 lists the results of individual iteration steps followed by a comparison of observed and calculated values with their differences obtained in the sixth iteration.

In each iteration, following the list of root-mean-squared deviations of fit, values of $\mathrm{H}_{i}{ }^{\mathrm{C}}$ and $\mathrm{C}_{i}{ }^{\mathrm{C}}$ were listed in "List of Corrections". The new parameters $\mathrm{C}_{i}{ }^{\mathrm{C}}$ and $\mathrm{H}_{\mathrm{i}}{ }^{\mathrm{C}}$, obtained from Equations 23 and 22, respectively, were then listed. Although six iterations were shown here, only five iterations were needed to give a good fit.
Tables 2 to 6 summarize the results of some examples. For the PDDS convoluted from two peaks at channels 200 and 210 with heights of 1500 and 500 occurrences, respectively, only three iterations are required to obtain a satisfactory result (Table 2). Table 3 shows that a PDD spectrum consisting of a symmetrical pair of Gaussians with a centroid space of ten channels requires only about six iterations. Three observed spectra shown in Figures 1 to 3 by dots were reconstructed and then deconvoluted. Results are given in Tables 1, 4,5 and 6. All converged quickly.

## Deconvolution of Observed PDD Spectra

More than 200 PDDS measurements were recorded from hydrogen-pitch two-phase flows in a 3.81 cm ID bubble column with and without continuous liquid flow (11) and have been successfully deconvoluted by the program developed.

Figures 1 to 5 show various shapes of PDDS (dots). They were deconvoluted to obtain the peak heights and positions using the numerical method described above.

The deconvoluted spectra are shown by vertical bars. The peak centre positions and heights resulting from deconvolution were used to calculate the PDD spectra shown by solid curves for comparison with the observed spectra. All of them show excellent fit between observed and calculated data.

## DISCUSSION

The problem considered is very similar to the analysis of seismic data or data in sonar or radar detections, in which deconvolution techniques are used for the interpretation of echoes due to a signal pulse of possibly unknown shape from objects of unknown position (19). Methods for dealing with this problem are commonly based on the Taylor minimizing technique (19) or the Baysian algorithm (20-23). Other methods were also used (24).
Both methods are similar to the theory described involving the formulation of recursion equations. The Baysian technique was originally formulated by the Fourier transform. Recently, Kennett et al. (20-23) formulated it by the Laplace transform method. The result of transformation forms a set of linear equations similar to Equations 17 and 18. They can be written in a recursion form to be solved by digital computer. It requires a large computer memory and a procedure to solve a large eigenvalue matrix. Therefore, for the problems considered, the present method is much more efficient.

The spectrum deconvolutions are very often used in optical spectroscopy to obtain electron, vibration, and rotational parameters as described by the so-called spectrum contour analysis (25). The analysis of ESCA and Mossbauer and other nuclear spectra is also identical to the optical spectral contour analysis. In these fields, the spectrum is convoluted by peaks with centres characterized by well-known formulae consisting of quantum numbers and parameters $(14,26)$. The deconvolution method described here can be easily applied to these fields.

Finally, the neglect of the random noise term $N(u)$ in Equation 1 can often be justified from the experimental set up. For example, as discussed in a previous report, the noise in the gamma-ray interrogation method can be suppressed sufficiently by using the narrow beam technique (10).

## ACKNOWLEDGEMENTS

The author sincerely thanks D.J. Patmore and W.H. Dawson of the Energy Research Laboratories, CANMET, and J.J. Lipsett of AECL-CRNL for their interest and encouragement during the course of this work.

The author also sincerely thanks his wife, Esther, for carrying out a major part of the literature survey and to Nita Harcourt for editing the text.

| After 2nd iteration | 202.7 | 2318.1 | 211.0 | 685.0 | 47.25 |
| After 3rd iteration | 201.0 | 1854.5 | 209.8 | 1055.8 | 58.54 |
| After 4 th iteration | 200.5 | 1622.2 | 211.6 | 1378.8 | 7.16 |
| After 5th iteration | 200.7 | 1553.9 | 210.8 | 1444.7 | 8.34 |
| After 6th iteration | 200.6 | 1478.8 | 210.7 | 1520.2 | 3.17 |
| After 7th iteration | 200.7 | 1510.0 | 210.7 | 1489.3 | 1.60 |
| After 8th iteration | 200.7 | 1497.7 | 210.7 | 1501.6 | 0.40 |

Table 5 －Results of iterations during PDDS deconvolution — Example 4

| Peak | 1 |  | 2 |  | 3 |  | 4 |  | RMS Deviation |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | CN非 | Peak | CH⿰⿰三丨⿰丨三一灬 | Peak | CH⿰⿰三丨⿰丨三一灬 | Peak | CH⿰⿰三丨⿰丨三一灬 | Peak |  |
| Input | 189.0 | 1523.9 | 219.0 | 781.6 | 255.0 | 335.6 | 289.0 | 73.4 |  |
| After Spectrum stripping | 195.0 | 1858.3 | 236.0 | 598.3 | 274.0 | 189.5 | 311.0 | 11.3 | 55.69 |
| After lst Iteration | 190.7 | 1643.1 | 226.0 | 605.6 | 264.0 | 316.2 | 301.0 | 119.7 | 70.18 |
| After 2nd Iteration | 190.1 | 1568.1 | 218.6 | 742.8 | 255.2 | 323.2 | 294.6 | 75.2 | 27.21 |
| After 3rd Iteration | 189.1 | 1516.0 | 219.5 | 793.7 | 255.6 | 337.4 | 291.3 | 68.0 | 4.32 |
| After 4th Iteration | 189.1 | 1524.8 | 219.6 | 781.4 | 255.7 | 355.9 | 289.4 | 72.2 | 0.50 |
| After 5th Iteration | 189.1 | 1523.8 | 219.6 | 781.6 | 255.7 | 335.5 | 289.4 | 73.3 | 0.03 |
| After 6th Iteration | 189.1 | 1523.8 | 219.6 | 781.6 | 255.7 | 355.5 | 289.4 | 73.4 | 0.04 |

Table 6 －Results of iterations during PDDS deconvolution－Example 5

| Peak | 1 |  | 2 |  | RMS <br> Deviation |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | CH\＃ | Peak | CH⿰⿰三丨⿰丨三一灬 | Peak |  |
| Input | 171.0 | 2753.0 | 203.0 | 27.6 |  |
| After spectrum stripping | 171.0 | 2754.7 | 205.0 | 26.9 | 0.63 |
| After 1st iteration | 171.0 | 2753.2 | 203.1 | 27.4 | 0.09 |
| After 2 nd iteration | 171.0 | 2753.0 | 203.1 | 27.6 | 0.00 |
| After 3rd iteration | 171.0 | 2753.0 | 203.1 | 27.6 | 0.00 |

## FIGURES

Fig. 1 - Observed and calculated PDD spectrum for Run 84-FD-946 at temperature of $200^{\circ} \mathrm{C}$, pressure of 2.76 MPa and superficial gas velocity of $0.00 \mathrm{~cm} / \mathrm{s}$

Fig. 2 - Observed and calculated PDD spectrum for Run 84-FD-615 at temperature of $200^{\circ} \mathrm{C}$, pressure of 13.79 MPa and superficial gas velocity of $1.77 \mathrm{~cm} / \mathrm{s}$

Fig. 3 - Observed and calculated PDD spectrum for Run 84-FD-657 at temperature of $200^{\circ} \mathrm{C}$, pressure of 13.79 MPa and superficial gas velocity of $1.31 \mathrm{~cm} / \mathrm{s}$

Fig. 4 - Observed and calculated PDD spectrum for Run 84-FD-990 at temperature of $200^{\circ} \mathrm{C}$, pressure of 2.76 MPa and superficial gas velocity of $2.38 \mathrm{~cm} / \mathrm{s}$

Fig. 5 - Observed and calculated PDD spectrum for Run $84-F D-681$ at temperature of $200^{\circ} \mathrm{C}$, pressure of 13.79 MPa and superficial gas velocity of $0.53 \mathrm{~cm} / \mathrm{s}$
