

1979 Review of Inshore Cod Stock
in Subdivision 4Vn (May-Dec.)

D. F. Gray, B. A. Fowler and O. V. Maessen

Marine Fish Division

INTRODUCTION

It is hard to divide the catch of cod in 4Vn (May-Dec.) between inshore and offshore stocks, and the usual split by gear has been assumed (Halliday, 1974). The inshore catch is taken to be all the Canadian catch other than by otter trawls. The total catch in 4Vn (M-D) dropped to a low of 4,000 tonnes in 1975 under a TAC of 10,000 tonnes. In 1976, the catch rose again to 6.5 thousand tonnes. After reviewing the situation, fearing that most of this catch was from the then depleted 4TVn (J-A) stock, the TAC was set at 3,500 tonnes in 1977 and 1978. Catches in these years were 8,000 and 5.5 thousand tonnes respectively. The inshore catch was also low in 1975 but dropped again in 1976, supporting the view that the higher offshore catches that year were from other stocks. The inshore catch rose to 3.3 and 3.9 thousand tonnes in 1977 and 1978. These catches reflect changes in catch per unit efforts.

CATCHES

Table 1 gives the catches by country for all of 4Vn (M-D) with a summary shown in Figure 1. Table 2 gives the breakdown of the "inshore" catch by gear, while Table 3 shows the monthly breakdown of all catch for the last three years. The concentration of catch by otter trawlers in the months of May, November, and December is evident and may indicate catches are from part of the 4TVn (J-A) stock. The catches by longliners are much more dispersed.

CATCH PER UNIT EFFORT

Catch per unit effort (when available) for otter trawls and longliners is summarized in Table 4. This is directed catch over directed effort for the months indicated. Figure 2 shows the longline CPUEs. Two series are given for tonnage class 2 that give credence to the belief that they fish the same stock throughout the period. Figures 3a and 3b show the OTB series. Again, two series are shown for tonnage class 4. These show more divergence than the two series for longline tonnage class 2, again supporting the belief that OTB catches early and late in the season are not from local stocks. Though most series show increases in recent years, there is little other agreement between the otter trawl and longline series.

Table 5 and Figure 5 show research population estimates. Table 5 gives the detailed estimates and derivation of the three-year moving average series for 4+, 5+, and 6+ numbers. These latter are plotted in Figure 5. These show similar trends to the CPUE series for longlines.

CATCH COMPOSITION

Figure 4 shows the proportional breakdown of inshore catch between longlines, handlines, gillnets and other gears. Seiners only took more than 10% of the catch in 1977.

Table 6 shows what age length keys and length and age distributions are available from catch sampling. In Tables 7 and 9, age compositions are given for sampled catches. This gives an idea of trends in the longline catch and the differences between age compositions of longlines, gillnets, and Danish seiners. It is felt that there are not adequate data to construct a complete catch at age table. Hence, no cohort analyses were run.

Tables 8 and 9 give weight at age by gear when available.

SUMMARY

Indications from inshore catch, commercial CPUE and research population estimates point to an improvement in recruitment to this stock. Since 4VsW cod and 4TVn (winter) cod show similar improvements, this is not unlikely. However, due to stock mixing, it is possible that the data are just showing the improvement of the other two stocks.
