# Assessment of Voisey Bay, Anaktalik Bay, and Okak Bay Arctic charr stocks in 1983 and projections for 1984 

## by

J. B. Dempson, and L. J. LeDrew Fisheries Research Branch Department of Fisheries and Oceans P.O. Box 5667

St. John's, Newfoundland A1C 5X1

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette sērie documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échëanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traitēs mais plutôt comme des rapports d'étape sur des études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscript envoyē au secrétariat.

#### Abstract

Using a method developed to account for the additional exploitation of the Anaktalik Bay Arctic charr stock in offshore fishing areas, cohort analyses were performed on adjusted catch at age data from 1977-83. Stock projections using population numbers generated from a terminal fishing mortality of 0.2 for Anaktalik Bay and 0.5 for Okak Bay indicated an $F_{0.1}$ yield in 1984 of $8 t$ and 27 t for the two stocks respectively. Owing to the low catch in Voisey Bay in 1983 and the problêm of not being able to account for Voisey Bay charr losses in the Antons area, it was decided that there was insufficient new information to recommend a TAC different from the 16 t quota of 1983.

Résumé A l'aide d'une méthode mise au point pour prendre en considération l'exploitation supplémentaire dont est l'objet la population d'omble chevalier de la baie Anaktalik dans les zones de pēche au large, des analyses de cohorte ont êtē effectuées sur des données revisẻes des prises par âge de 1977 à 1983. Des projections de stock effectuées à partir des chiffres de population obtenus par une mortalitē par pêche de dernière année de 0,2 pour la baie Anaktalik et de 0,5 pour la baie 0kak rēvēlaient un rendement à $\mathrm{F}_{0.1}$ en 1984 de 8 t et de 27 t pour les deux stocks respectivement. En raison de la faiblesse des prises dans la baie Voisey en 1983 et de l'incapacitē de prendre en considération les pertes d'omble chevalier de la baie Voisey dans la rêgion de Antons, on en est venu à la conclusion qu'on ne disposait pas d'information nouvelle suffisante pour recommander un TPA différent du contingent de 16 t de 1983.

## Introduction

Catch statistics from the Arctic charr fishery in Voisey Bay, Anaktalik Bay, and Okak Bay (Fig. 1) have been available since 1974. Quotas have been applied to Voisey Bay and Anaktalik Bay catches since 1979 and Okak Bay catches since 1981 (Dempson and LeDrew, 1982). Quotas were obtained in Voisey Bay in 1979 and 1981 and in Anaktalik Bay in 1981 and 1982. The 1983 quotas of $16 t$ and 11 t for Voisey and Anaktalik Bay respectively were not reached but the Okak Bay quota of 21 t was surpassed. The expansion of the northern Labrador Arctic charr fishery into the Hebron-Saglek region in 1981-82 resulted in a redistribution of fishing effort away from these areas. Increased catch per unit effort for Arctic charr in offshore fishing areas suggests increased movement out of the inner bay areas in recent years.

This paper examines the results of the 1983 fishery and provides an outlook for 1984.

Catch and effort data
Landings of Arctic charr from 1974-83 are summarized in Table 1. Catches in 1983 from Voisey Bay and Anaktalik Bay were very low. Fishermen, anticipating a fishery in the Hebron-Saglek region, were reluctant to devote themselves to a fishery in the Voisey-Anaktalik area until it was confirmed that the northern fishery would not occur. The increased catch per unit effort of charr in the offshore areas suggests that by early-mid July many charr had moved into offshore areas. As a.result, catches from these two areas were the lowest or second lowest on record as were the catch per unit effort estimates.

The Okak Bay catch of 31 t was back at levels attained in 1977-79. The decreased effort in 1981 and 1982 was largely the result of the expanded northern fishery.

Catches of Arctic chary in the offshore fishing areas of Dog Island and Black Island have increased over the past several years and these fish are largely from the inner bay areas. The same method used to apportion Tikkoatokak Bay catches into inshore and offshore components was applied to both Voisey Bay and Anaktalik Bay catches in order to provide a more complete evaluation of total stock losses by the commercial fishery.

Recaptures of Voisey Bay charr in the Anton's area indicate that Voisey Bay charr are caught in varying numbers in this area as well. Losses to the Anton's area, however, cannot as yet be quantified.

A similar problem exists in the Okak Bay area where the catch of Arctic charr in the offshore Cutthroat region is likely composed of a composite of stocks from Okak Bay, Napartok Bay, and the Kiglapait area. From 1979-83 landings of Arctic charr from the Cutthroat area have averaged 26.4 t . The geographic position of Cutthroat in relation to Okak Bay (Fig. 1) would tend to indicate that a substantial portion of the catch is of Okak Bay origin which to date have not been accounted for in assessments of the Okak Bay charr stock.

Information, however, is not available to apportion the Cutthroat catches back into the respective inner bay or coastal areas.

Adjusted catch data are summarized in Table 2 for Voisey Bay and Anaktalik Bay. For Anaktalik Bay, the impact of adjusting catch data is substantial only for the last five years. Owing to the low catch in Voisey Bay in 1983 and the problem of being unable to account for Voisey Bay losses in the Anton's, area, it was decided that there was insufficient new information to recommend a TAC different from the 16 t quota of 1983.

Numbers at age were available from annual commercial sampling programs for Okak Bay charr since 1977 (Table 3). For Anaktalik Bay, numbers at age were available from 1977-78 and 1980-83. An estimate for numbers at age in the 1979 catch was derived from average proportion at age for 1977-78 and 1980-82 (Table 4a adjusted catch, $4 b$ non-adjusted catch).

Weights at age were calculated from commercial samples (1974, 1977-78 for yield per recruit analysis, and 1982-83 for stock projections) and were converted from gutted head-on to whole weight using the conversion factor 1.24 (Coady and Best, 1976) (Table 5).

Partial recruitment rates were calculated from a matrix of fishing mortality rates generated from cohort analyses run on 1977-83 data. F values were averaged at age for 1977-81 and are presented in Table 5.

Yield per recruit was calculated by the method of Thompson and Bell (Ricker, 1975) using partial recruitment values and mean weight at age data from 1974, 1977-78. Natural mortality was assumed constant at 0.2. Age range extended from 6-15 for Voisey Bay, 6-16 for Anaktalik Bay, and 6-20 for Okak Bay. Fo. 1 values were: $0.3979,0.4050$, and 0.4013 for Voisey Bay, Anaktalik Bay, and Okak Bay respectively. Tikkoatokak Bay had a value of 0.3868 (0.39). Owing to the fact that all input parameters are subject to error and the similarity of the values, all $F_{0,1}$ values were standardized at 0.39 ; the first value chosen and used for Tikkoatokak Bay. $F_{0,1}$ values for Anaktalik Bay and Okak Bay are lower than estimates used in previous assessments (Dempson and LeDrew, 1983). The lower updated values resulted from using longer age span and historical weight at age data.

Total mortality rate (z) calculated using the Paloheimo method gave an average value of 0.61 for Okak Bay ( averaging 1979-80 to 1982-83 except 198182 where $z=0.10$ ) (Table 3). The total mortality as estimated from a catch curve was 0.66 ( $95 \%$ C.L. $=0.56-0.75$ ) and estimates the average mortality in effect from 1974-75 to 1981-82. Owing to the large variation in catch per unit effort at age data for Anaktalik Bay, an estimate of total mortality was also derived from a catch curve. The total mortality rate of 0.57 (95\% C.L. $=0.31$ 0.84), however, refers to the average mortality in effect from 1976-77 to 1981-82 and is likely an overestimate in relation to the decrease in both catch and effort during the past several years.

Cohort analyses for Okak Bay were performed using terminal fishing mortalities ranging from 0,4 to 0.6 . The $r^{2}$ values for regressions of $F$ on effort showed little variation ( $r^{2}=0.92-0.94$ ) Table 6 . For regressions of biomass on
catch per unit effort highest $r^{2}$ was at $F_{T}=0.6\left(r^{2}=0.89\right)$ but this appears high in relation to other areas. As the estimated average total mortality rate derived from a catch curve was 0.66 ( $F \approx 0.46$ ), and considering the above information, an $F_{T}$ of 0.5 was used for 1983.

With $F_{T}=0.5$ and fishing at $F_{0.1}$, the projected available catch for the Okak Bay stock in 1984 is 27 t ( $\operatorname{Table}^{-1} 7$ ) and it is recommended that this is the TAC for 1984. The long-term projected catch (recruits of $39,601 \times$ yield per recruit of 0.796 kg ) is 29 t . It is recognized that Okak Bay Arctic charr stocks likely contribute to the charr fishery in the Cutthroat area and that attempts should be made to clarify the contribution and thus be able to account for the total losses of Okak charr in the commercial fishery.

Given the low estimated catch for Anaktalik Bay Arctic charr in 1983, and that the catch curve total mortality rate refers to the period of time when these fish were being recruited into the fishery, a stock projection for 1984 was run using a terminal fishing mortality of 0.2 . The projected available catch at $F_{01}=0.39$ is 8.2 t (Table 7); a decrease from last years TAC of 11 t , and it is recommended that this is the TAC for 1984. In comparison, the long-term projected yields at $F_{T}=0.2$ and $F_{T}=0.3$ were 12.8 and 10.8 t respectively (recruits of 11,178 and 9,417 with a yield per recruit of 1.143 kg ).

The projected available catch for Anaktalik Bay can be apportioned into respective offshore and inshore allocations. The approximated inshore and offshore catch for 1984 is 6.1 t and 2.1 t respectively, which could range from 4.8-7.0 $t$ inshore and 1.2-3.4 $t$ offshore.
