PREFACE

A soil survey of the Ontario Regional Municipality of Haldimand-Norfolk has recently been completed and published as Report No. 57. Soil surveys describe the pedological aspect of soils and their application to agriculture and other land uses. Engineers and planners also make use of soil survey information. The publication is complementary to the Haldimand-Norfolk soil survey report. Graphic illustrations are provided to supplement the written descriptions given in the report. It is presumed that engineering users of soil surveys require information about the landscape and its soil characteristics. The term pedotechnical defines this special use and the object of this publication is to encourage more effective use of soil surveys by these professionals.

PREFACE

Des travaux de prospection pédologique ont pris fin récemment dans la municipalité régionale de Haldiman-Norfolk, en Ontario, et ont été publiés dans le rapport n° 57. Ils décrivent les aspects pédologiques des sols et leur application en agriculture et à d'autres usages. Des ingénieurs et des planificateurs utilisent aussi à ces fins les données de la prospection pédologique. Cette publication complète le rapport sur les travaux de prospection à Haldimand-Norfolk. Ces graphiques illustrent les descriptions présentées dans le rapport. On a supposé que les spécialistes utilisant la prospection pédologique désirent avoir des informations sur le paysage et sur ses caractéristiques pédologiques. Le terme pédotechnique définit cet emploi particulier, et la présente publication a pour but de favoriser une meilleure utilisation des données de prospection par ces spécialistes.

ACKNOWLEDGEMENTS:

I would like to thank the many people who have cooperated in this work including the soils, secretarial and cartographic staff of the Land Resource Research Institute and the Ontario Institute of Pedology. Special thanks are given to Mr. E. Presant, Ontario Institute of Pedology.

INTRODUCTION

This publication concerns interpretations for the recently completed Haldimand-Norfolk Soil survey (Presant et al. 1984). It has been customary for many years to include "engineering sections or interpretations" with Canadian soil survey reports (Pawluk, 1968) and to encourage more effective use by planners and engineers (civil as well as agricultural). In response to requests by the Expert Committee on Soil Survey for improved interpretation methodology, pedotechnical interpretations were proposed. The following demonstrates the application of this approach to a very extensive modern survey.

NATURE OF THE INFORMATION:

A great deal of information is obtained during soil survey and most of it is contained somewhere in the soils report. For reference purposes a requirement exists for better presentation for ready use. This is done in the first instance by separating general information from the detailed. The occasional user may choose to refer only to the general information. For engineering users these terms may also have a different meaning and it is necessary to emphasize that detailed refers to detailed descriptions of (generalized) mapping units. The information usually does not apply to specific sites within any map unit - site information must be obtained separately and in addition to the mapping for specific site applications.

For interpretation purposes a requirement to separately illustrate the type of information needed by engineers as contrasted to planners is recognized. For the former, LANDSCAPE interpretation are provided on the premise that information concerning the landscape and its soil characteristics is required. Access to this information is provided by keys to the map and examples of use.

For planners, LAND USE interpretations are provided on the premise that information concerning the application of soil information to land use planning is the most pressing need. Keys to the map and examples of use are separately given.

KEY TO LANDSCAPE INTERPRETATIONS

This key is to help engineering readers make use of the soils map and report to develop a better understanding of the lie of the land. It consists of a number of tables. Listed alphabetically in the first column of Table 1 are the major map unit component symbols of the map units used in the Haldimand-Norfolk soil survey. The 2nd and 3rd column refer the reader to the general and detailed information respectively. The general information is all given on a single page (Table 2) termed "Landscape setting legends", where each of these map unit components is illustrated. This information is complementary to the general legend of the soil survey map.

The third column of Table 1, refers the user to the detailed information on the pedotechnical settings (Appendix 1). The settings illustrate as closely as possible, the concepts of the central theme of the map unit components. The data does not refer to any particular site nor to modal sites within any delineation, although information may have been obtained from specific sites considered to be typical for the map unit component.

Most of these map unit components represent soil series.

EXAMPLE ILLUSTRATING LANDSCAPE INTERPRETATIONS:

(a) General interpretations:

If the symbol LIC occurs in any delineation on the soils map, it infers that the most prevalent soils in that area are likely to be those which are best described by the LIC map unit component. Table 1 lists this map unit component, (LIC refers to the Lincoln soil series) as being illustrated in Legend I on the Landscape Setting Legends (Table 2). Legend I of Table 2 shows that LIC soils illustrated as D on the cross-section diagram, are typical of the poorly drained (P) member of the "D" catena* of soils (SHV, HIM and LIC).

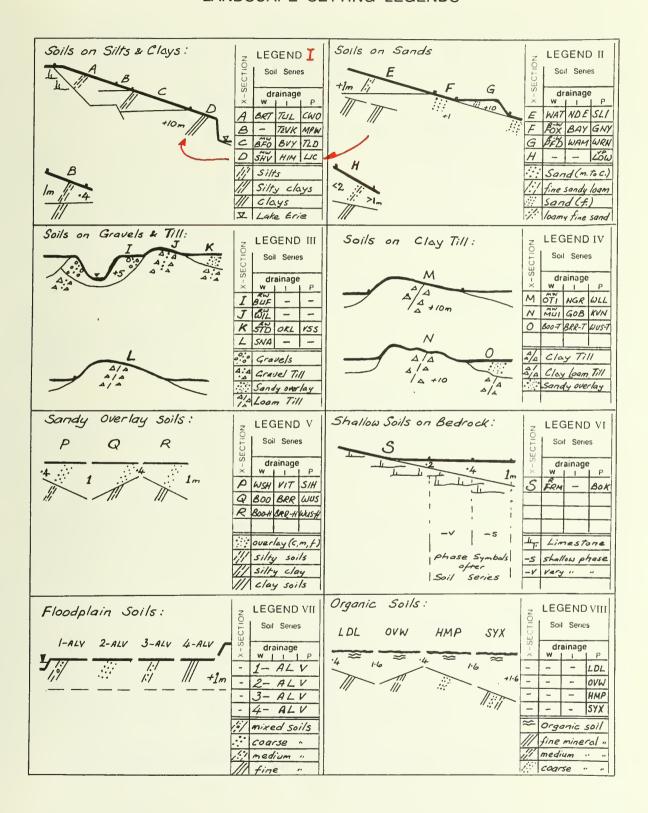

^{*} Catena - a non taxonomic grouping of a sequence of soils of about the same age, derived from similar parent materials, and occurring under similar climatic conditions, but having unlike characteristics because of variations in relief and in drainage (from AG. CANADA "Glossary of Soil Science terms").

LANDSCAPE SETTING LEGENDS

The cross-section indicates that this" D" catena of soils comes under the general heading of soils on silts and clays. The D soils have developed on the clay section of this silt-clay landscape sequence. The clays are deep, generally more than 10 meters thick (+10m), typically found on the Haldimand plain north of Lake Erie. The cross-section also shows that this catena of soils merges with soils of the "C" catena (BFO, BVY, TLD) which usually occurs at higher elevations further from the lake, and which have siltier textures; and also with the "A" catena (BRT, TUC, CWO) which has developed on the still coarser, deep silty soils occurring at somewhat higher elevations. It should be noted that the "B" catena constitutes an "overlay" soil where the silts are only between 0.4 and 1 m in thickness over clays. No well drained member was mapped in the "B" catena.

It is possible to use only this general information and make good use of the soil survey map for a variety of purposes. Indeed this is as far as many users may need to go. The soil survey field and laboratory data, however, does provide a considerable amount of additional information. To utilize this more detailed information, reference is then made to the third column of Table 1.

(b) Detailed interpretations:

Referring to Table 1, it is noted that detailed information for the Lincoln (LIC) soils is given in appendix I on P/T setting sheet SHV which applies to all soils in that catena. The standard key to the symbology used on the P/T setting sheets is explained in Pedotechnique (Wilson 1982). But

for the specialist user of this type of information it is possible to illustrate its use more briefly here with the key to the pedotechnical setting sheet (Fig. 1) and also with the example given by the LIC symbol.

Fig. 1 is a blank P/T setting sheet with brief explanatory notes. These notes indicate that the general landscape concept as previously explained, is reproduced as module 1; under the heading "1. LANDSCAPE X-SECTIONS".

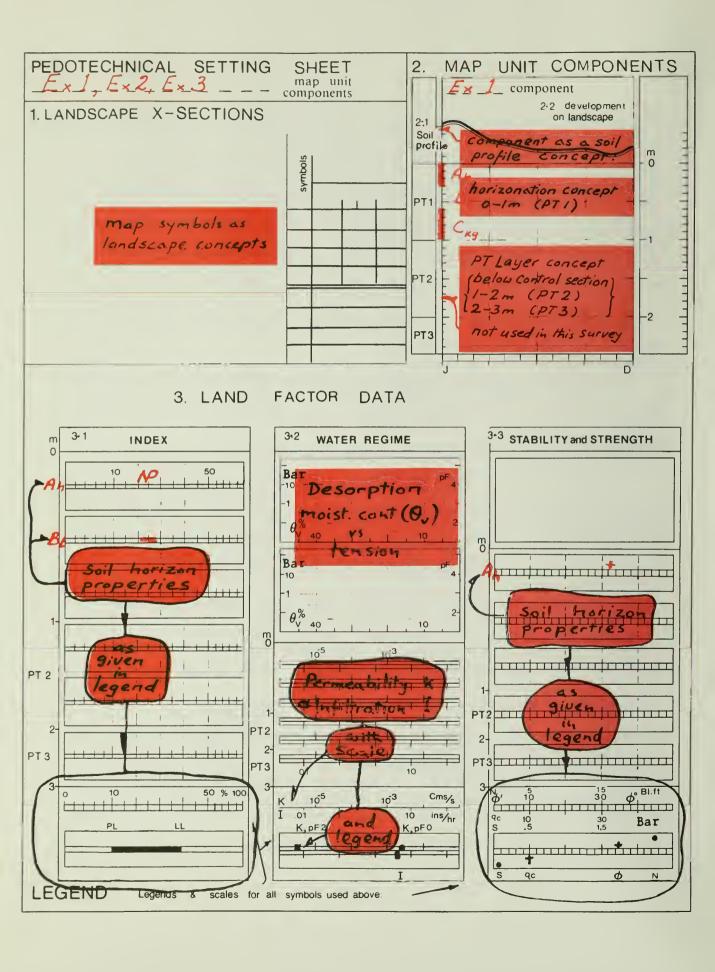

Typical soil profiles, landscape position, etc are given in module 2 entitled "2. MAP UNIT COMPONENTS".

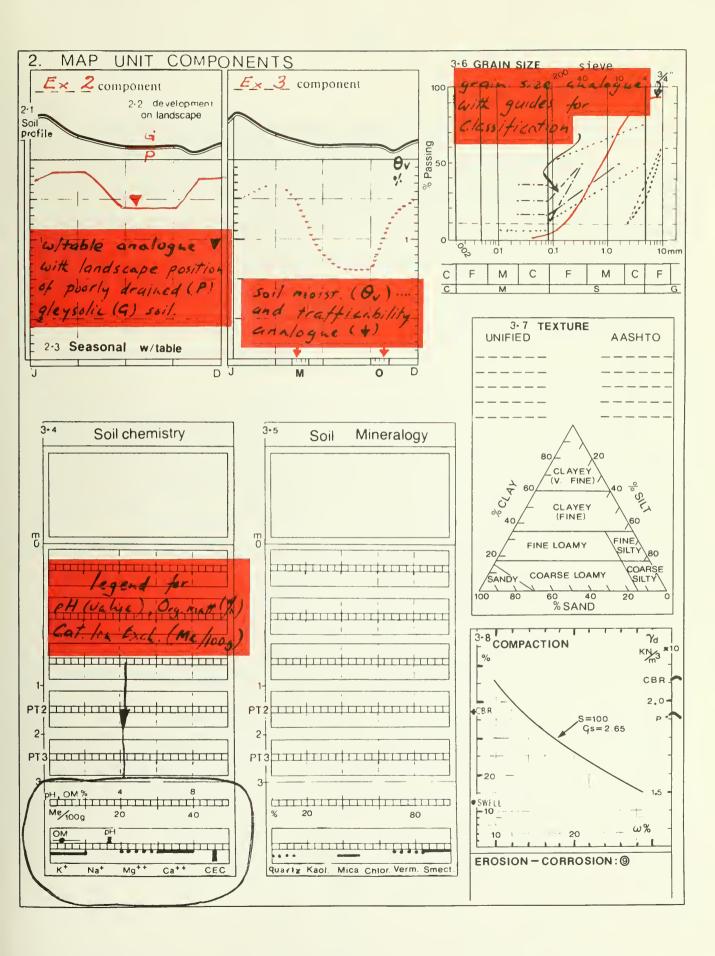

The map unit component concepts are further described in terms of grain size distribution, plasticity, etc which are included in module 3, as "3.

LAND FACTOR DATA".

Continuing with the previous example; according to Table 1 the detailed interpretation of the LIC map unit component is given on P/T setting sheet SHV (Appendix I). Module 1 on this sheet again shows that the LIC symbol refers to the poorly drained member of the Smithville (SHV) catena and illustrates the general setting on the landscape as described previously.

Module 2 indicates that this poorly drained (P) condition refers to a position on the landscape (2.2) where gleysolic soils (G) developed on flat lying ground as a result of groundwater table conditions (2.3) in which the piezometric level (∇) in the Bg soil horizon does not drop more than 0.10 to 0.40 m below the ground surface for most of the year except at mid-summer (the ordinate scale is depth, m; the abscissa is a yearly time scale Jan.

(J) to Dec. (D)). For the Lincoln soils (LIC), the water table is generally not perched; the piezometric level in the Ckg horizon is somewhat less than it is in the Bg horizon indicating downward movement of ground water throughout the year. The soil profile (2.1) indicates that below the cultivated surface horizon Ap (.20 m thick) there is a gleyed horizon Bg (0.2 m thick), and the parent material horizon Ckg is also gleyed.

The grain size distribution curve, (Module 3.6), shows the Bg and Ckg horizons to be similar, with clay contents around 60% which classify the texture of the soil as clayey or very fine, (Module 3.7).

The index properties shown on Module 3.1 indicate the Ckg horizon to be clay of low plasticity, but with high plasticity characteristics in the Bg horizon (LL 50%); shrinkage limit (SL) just below the PL indicating non-elastic parent material soils; porosity is 35%. Combining this plasticity data with the grain size curves exhibited, and using interpretation sheets (Wilson 1982), the C horizon soils have been classified in the range of CL (Unified) and A-7-6(12) (AASHTO) in Module 3.7. Compaction characteristics (Module 3.8) are normal for silty clay, with CBR (γ_d) values of 1.5 at optimum water content of 27%. The moisture availability is not high (Module 3.2), with 10% available between field capacity (1/10 bar) and wilting point (15 bar). Hydraulic conductivity (K) is very low at less than 1 x 10-6 cm/sec, although infiltration rates (I) have not been measured.

This method of presenting soil survey information sets the stage for its use by other interest groups. A recent example involved specialists concerned with the soil moisture and farm equipment operation. Combining the index, water regime and climatic data the soil moisture analogues and dates for the ground being trafficable 80% of the time were compiled. The method is described, Dyer 1984 and 1985. The analogues are presented on Module 2; the trafficability probability dates (by the arrows) and the soil moisture (by the dotted lines).

APPLICATION OF SOILS INFORMATION

For planning, engineering and other non-biological applications of soil survey, interpretations are normally made for land use purposes, (Soil Survey Staff, 1975). For every project involving a change of land use, the value of prime agricultural land should be considered as a first priority. This does not necessarily imply safeguarding individual cultivated areas but rather maintaining the integrity of larger regions well-suited for commercial agriculture. The Haldimand-Norfolk soil report discusses agricultural interpretations which include land capability and crop suitability ratings. These can be used as a guide to the impact of projects involving land use changes. Other engineering land use interpretations are given below. They include interpretations for land use changes associated with such activities as the extraction of material for construction purposes and the use of the land for building site development. The method used in developing ratings with these interpretations is adopted from procedures

described by Marshall et al. (1979) for agricultural capability. However the intent is quite different and instead of referring to capability, the procedure is termed Land Factor Ratings".

Land Factor Ratings

A major difference of land factor rating from capability rating is that the pedotechnical scheme refers only to specific land factors important for the use considered, whereas capability for agriculture is a comprehensive rating of the land for general agriculture. In considering the suitability for the land for septic tanks for example, the soil survey information could be used for a basic classification because most factors controlling biological filtration in the soil are already encompassed in agricultural capability ratings. But official ratings of the land for the use of septic tank effluent disposal may also require consideration of certain other factors not fully encompassed during the soil survey operations. (eg. the geo-hydrological conditions of specific areas).

Classes and subclasses are used in the land factor rating system as discussed below:

Classes

The classification scheme is comprised of seven (7) classes according to the likelihood of encountering problems (limitations) for the uses being considered. These seven classes provide the user with information about the degree and kind of limitation for broad planning purposes and for assessment

of mitigation measures. These classes are:

Class Ul: Land having factors indicative of <u>UNLIKELY</u> soil problems for the use considered.

Classes P2 to P4: Land having factors indicative of <u>POSSIBLE</u> soil problems for the use considered.

Classes L5 to L7: Land having factors indicative of LIKELY soil problems for the use considered.

Subclasses

Subclasses are divisions within classes having similar kinds of limitations or problems. These define the land factor problems for the use.

The list of subclasses given below applies to two interpretations which have been made for this report, namely septic tank absorption fields, and dwelling sites. A third interpretation, location of construction materials, follows this discussion.

Septic Tank Interpretation:

Subclasses Ds - Stony ground affecting tile trench excavation; stoniness above lm.

Ds' - Stoniness at surface

Dr - Depth to bedrock or hardpan; depth between 1 to 2m.

Dr' - At surface (to lm)

Dc - Depth to impervious layer; impervious layer
between 1 to 2m

Dc' - Impervious layer at surface (to lm)

Dw - Depth to water table;

water table between 1 and 2m

Dw' - Water table at surface (to lm)

Nn - Nitrogen attenuation problems due to highly pervious layer between 1 & 2m.

Nn' - Highly pervious layer at surface (to lm).

Np - Phosphorus retention problems due to lack of fixation sites between 1 and 2 m.

Np' - Inadequate fixation near surface (to lm).

Ss - Unfavourable land slopes

Class E slopes: (9-15%)

Ss' - Slopes above Class E (and Class"A" depressional)

Si - Pollution hazard due to inundation by overland flow or very poorly drained soil

Si' - In predicted floodplain area.

Dwellings Interpretation:

Subclass Es - Stones interfering with excavation; stones at

less than lm

Es' - Stones at surface

Er - Excavation problems;

Bedrock (or hardpan) between 1 & 2m

Er' - At less than lm

Ew - Wet excavation problems; unstable soils between 1 & 2m

Ew' - At less than lm

Fb - Flooding basement hazard; wet pervious zone, between 1 & 2m

Fb' - At less than lm

Fi - Inundation of land;
by overland flow (very poorly drained)

Fi' - Within floodplain

Hf - Hazard due to frost heave; susceptible soils between 1 & 2m

Hf' - From surface to lm

Hc - Hazard due to swelling clays; susceptible soils from surface to 2m

Hc' - From 2 to 3m

Hr - Hazard due to expansive rock; susceptible rock between 1 & 2m

Hr' - From surface to lm

Sb - Hazard due to differential settlement; weak soil within 4m

Sb' - Very weak soils within 4m

So - Hazard due to organic soil subsidence; soils with peaty phases

So' - Organic soils

St - Hazard due to soil shrinkage; borderline soils within 4m

St' - Shrinkable soils within 4m

Construction Materials Interpretation:

A similar procedure can be used to indicate the "potential of a soil for a use" rather than limitations for a use. This was done for interpreting the suitability of various soils for construction materials. In this instance the land factor classes are defined as follows:

Class UI : <u>Unlikely</u> potential for location of construction materials.

Classes P2 to P4: <u>Possible</u> potential for location of construction materials.

Classes L5 to L7: <u>Likely</u> potential for location of construction materials.

Subclass F - Potential sources of roadfill; thickness more than

lm (with less than lm overburden);

F' - More than 2m in thickness

G or S - Potential sources of sand(S) or gravel (G); more
than lm (with less than lm overburden)

S' or G' - More than 2m in thickness

R - Potential sources of rockfill (R); bedrock, with between 1 & 2m overburden

R' - Bedrock, with less than 1m overburden

Guidelines Used in the Rating Scheme:

The land factor classification is developed for components of soil map units for which the relevant land factors are identified and separated. The pedotechnical setting sheet permits the central concept of the various soil series, soil phases and miscellaneous land units (soil map unit components) to be identified in terms of land factors such as grain size and compaction characteristics of the soil, etc. A number of specific problems to which the land factors relate are identified for each interpretation.

Interpretation sheets (Appendix II) illustrate these problems and provide tables to obtain the subclasses, using the setting sheet as the source of information. The subclasses are grouped according to their combined

potential or limitation for the particular land use considered.

The example given below is for the septic tank interpretation. The use of the land for disposal of septic tank effluents is seen as a pollution problem and three specific problems are identified. Land factors are grouped according to these basic problems:

I/ Limitations due to depth limits (D) which define the boundaries of the soil as an effective biological filter.

II/ Limitations due to the degree to which the biological filter (soil) is effective for nutrient attenuation (N).

III/ Limitations due to the setting (S) of the mapping unit on the landscape relative to potential pollution hazards.

Interpretation Sheets D, N and S (Appendix II) permit land factor subclasses (as previously listed) to be determined from the setting sheets for each map unit component. For example on interpretation sheet "D", (Fig. 2), it is seen that the problem has been interpreted in terms of the mitigation measures required to correct the deficiency. The extra amount of fill required to bring the land to an acceptable standard for this land use, provides a rating in quantitative terms. For the 'D' sheet these ratings are:

UNLIKELY - no extra fill required;

POSSIBLE - up to lm of fill required;

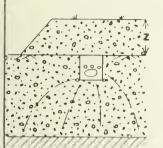

LIKELY - more than lm of fill required.

INTERPRETATION

SEPTIC TANKS

SOIL PROBLEMS DUE TO

DEPTH OF SOIL FILTER, D

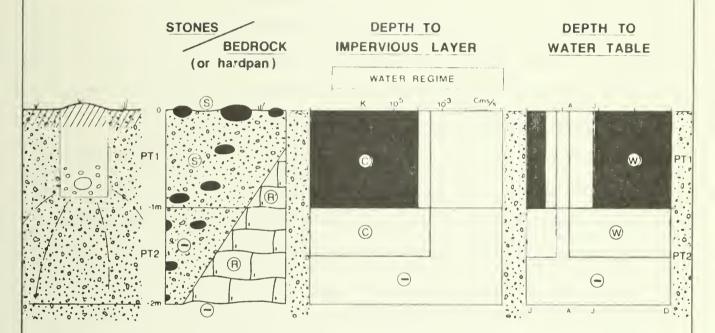

PROBLEM

Extra Filter (z) Required

FACTORS CONSIDERED

Depth to Bedrock (and hardpan)	Dr
Presence of Stones	Ds
Depth to Impervious Layer	Dc
Depth to Water Table	Dw

INTERPRETATION

PROBLEM CLASS	STONES in PT1 lay		BEDROC AND HARD		IMPERVIO LAYER		WATER TA	BLE
UNLIKELY	below PT1	_	below PT2 🕣	-	zone 😑	-	within zone	-
POSSIBLE	at surface only S	Ds	in PT2 only	Dr	zone C	Dc	within zone W	Dw
LIKELY	in PT1 S'	Ds'	in PT1 (R')	Dr'	within zone C'	Dc'	within zone W'	Dw'

The different land factors contributing to this depth deficiency are listed as the presence of stones (s), the presence of bedrock or hardpan (r), the presence of an impervious layer (c), and the presence of a high water table condition (w). The method of rating is to compare the information on the appropriate module of the setting sheet with that of the interpretation sheet. On the interpretation sheet (D), the column entitled "Depth to impervious layer", shows 3 envelopes; one with the symbol ("C", one with the symbol "C" and another with the symbol "-"). The C' symbol indicates that any soil between the ground surface and a depth of lm (i.e. the PT 1 layer), which has a K value of 10-4 cm/sec or less (i.e. an infiltration rate of less than 0.5 in./hr) is given the LIKELY rating, Dc' for the land factor C (presence of impervious layer at shallow depth). A borderline condition is recognized for soils with infiltration rates between 1" and 0.5 in./hr in the top metre. The borderline (POSSIBLE) rating, Dc is also given for soils with infiltration rates less than 0.5 in./hr but which are between 1m and 2m below the ground surface. For all other conditions the UNLIKELY rating "-" applies.

The soil unit components of the Haldimand-Norfolk Region were classified into seven (7) land factor classes following the procedure described. This provides for a ranking of the map components according to the severity of the problem. The scheme in detail is shown below;

LAND FACTOR CLASS		INTERPRETATION
SEPTIC TANKS		
UI	-	Pollution problems unlikely: mitigation methods
		should not be required.
P2	-	Possible problems due to depth (Ds, Dr, Dc, Dw):
		mitigation may require < lm of fill.
Р3	-	Possible problems due to nutrients (Nn, Np);
		further investigation is required.
Р4	-	Possible problems due to setting (Ss, Si);
		mitigation may require design modifications.
L5	-	Likely problems due to depth (Ds', Dr', Dc', Dw');
		mitigation should require > lm of fill.
L6	-	Likely problems due to nutrients (Nn', Np');
		mitigation should require special construction
		methods.
L7	-	Likely problems due to setting (Ss', Si'); serious
		problems not likely to be mitigated.

KEY TO LAND USE INTERPRETATIONS:

The key to general land use interpretations is given on Table 4. It illustrates how the reader can make use of the rating symbols given in Table 3, for interpretation purposes. The LIC map unit component is used for the illustration; the rating for septic tanks for this map unit component is obtained from Table 3 as L5Dc'w' (column 2). The most general interpretation of this symbol, Table 4 is shown to be that pollution problems are LIKELY (L) to result if septic tanks are used on this type of land. This is the most general level of the land use interpretations and it may be as far as many users of this information need to go.

It is possible however, to progress beyond this as shown on Table 5 which provides the key to detailed land use interpretations. The rating L5Dc'w' could also denote that the land factors contributing to this rating are due specifically to the lack of sufficient depth (D) of aerated soil due to the presence at shallow depth of an impervious layer (c') and the water table (w'). It is further implied that the problem could be mitigated, but this could require the addition of more than lm of pervious fill. Table 3 lists the map unit components and their ratings for the 3 land use changes considered i.e. septic tanks, dwelling sites and extraction of construction materials.

EXAMPLE ILLUSTRATING LAND USE INTERPRETATIONS:

If the symbol LIC occurs in any delineation on the soil map, it infers that the most prevalent soils in that area are likely to be those best described by the LIC map unit component. Table 3 gives, for this map unit component, the ratings L5Dc'w', P4HfSb and UI for land use changes due to installation of septic tanks, dwelling sites and extraction of construction materials, respectively. These ratings can be generalized by considering only the first letter i.e. L, P and U. As indicated in Table 4, these symbols can be interpreted as indicating severe pollution problems to be likely (L) if septic tanks were used without strict control at dwelling sites where soil problems (P) could occur, suggesting the land is only moderately suited for this purpose. The land is unlikely to be a resource for construction materials (U). Thus it might be better to leave such land in agriculture since it is generally unsuitable for septic tanks or construction materials. However if dwelling sites were to be seriously considered, it would be advisable to have soils experts report on septic tank waste disposal systems and to carry out tests on the soils, especially the deeper soils, to verify their competence for building foundations.

If two components are included in a map unit e.g. LIC (Lincoln) and FRM (Farmington), in approximate proportions of 70:30, the above remarks would only apply to the soils occupying about 70% of the area. For the remaining 30% of FRM soils, Table 3 (map unit component FRM) would indicate L5, L5 and L7 for the same uses. Similar remarks as given above for the LIC symbol might apply to the use of septic tanks and dwellings for this other type of land, but for different reasons. There could also be possible land use conflicts with quarry operations (L7), but little conflict with agriculture (agricultural capability would only be rated as Class 6).

HOW TO USE THIS PUBLICATION

If the reader is only interested in the general role of the Haldimand-Norfolk soils map in planning or for similar regional problems, reference could be made directly to the section explaining the (key to land use interpretations) and to Table 3.

If on the other hand the reader is only interested in obtaining a general appreciation and understanding of the soils in the area, reference could be made directly to the section explaining the (landscape interpretations) and to Table 2. For these purposes it should be noted that the information given applies to the entire area delineated and not to any particular site within these delineations.

Users interested in developing a working knowledge of the soils and an ability to efficiently use the soils map would be advised to consider both

sections of this publication and also to consult the Haldimand-Norfolk soil survey report. Finally it may be said that there are also other survey records, (geological, hydrological, ground water, terrain analysis and others) from provincial, federal and private agencies which should be consulted for a full appreciation of the land resources of this region.
