INTRODUCTION TO THE GUIDE:

The Cruciferae family, which contains about 3500 species and 350 genera, is one of the ten most economically important plant families (Rich 1991). The tribe Brassiceae is one of the 13-19 tribes which have been recognized within the family and is one of the few tribes believed to constitute a natural group (Hedge 1976, Al-Shehbaz 1984, 1985). It is the most important economically and the most distinctive (Gómez-Campo 1980a, Al-Shehbaz 1985). It is distinguished on the basis of the presence of conduplicate cotyledons (i.e. the cotyledons are longitudinally folded around the radical) and/or two-segmented fruits (siliques) which contain seeds in one or both segments, and only simple hairs if present (Gómez-Campo 1980a, Al-Shehbaz 1985).

Crop brassicas display enormous diversity and are used as a source of oil, vegetables, mustard condiments, and fodder. Those of particular importance in Canada are: *Brassica napus*, *B. rapa*, and *B. juncea* as sources of canola oil, and *B. oleracea* as cole-crops. The genera *Raphanus* and *Sinapis* are also of major importance, the former cultivated for its edible roots and the latter as a source of mustard condiments along with *B. nigra*. Several species have become naturalized weeds in Canada and the United States [eg. *Sinapis arvensis* (wild mustard), *Raphanus raphanistrum* (wild radish), and *B. rapa* (wild rape)], representing both a potential source of germplasm and agricultural problems. In other areas of the world *Crambe* is cultivated as an industrial oil, and the leaves of other genera (eg. *Eruca* and *Diplotaxis*) are eaten as salad greens.

An understanding of the genetic potential of wild relatives of the crop species of *Brassica* and allied genera (members of the Tribe Brassiceae) is critical for the establishment of long-term breeding programs of these crops. In addition, it is clear that many of the wild species in the tribe have potential value as new crops, as sources of industrial oils (*Crambe*, *Eruca*), condiments (*Sinapis alba*), and other diverse products. Wild relatives also possess a number of useful agronomic traits which could be incorporated into breeding programs, including: cytoplasmic and nuclear male sterility; resistance to disease and insect and nematode pests; intermediate C₃-C₄ photosynthetic activity; and tolerance of cold, salt and drought conditions.

The last comprehensive taxonomic treatment on the tribe was conducted by Schulz (1919, 1923, 1936). The tribe Brassiceae contains approximately 217 species and 51 genera, 25 of which are monotypic (Table below). Geographically, it is centered in the southwestern Mediterranean region, particularly Algeria, Morocco and Spain, where c. 41 genera are either endemic or exhibit maximum diversity. The tribal range extends eastward into India and Pakistan and southward into South Africa, with a poor representation in the New World (Hedge 1976, Gómez-Campo 1980a, Al-Shehbaz 1985).

GENERAL OF THE TRIBE BRASSICEAE (no. species in brackets)

Ammosperma (2)	Guiraoa (1)
Boleum (1)	Hemicrambe (2)
Brassica (35)	Henophyton (1)
Cakile (7)	Hirschfeldia (2)
Carrichtera (1)	Kremeriella (1)
Ceratocnemum (1)	Moricandia (9)
Chalcanthus (2)	Morisia (1)
Coincyia (6)	Muricaria (1)
Conringia (6)	Otocarpus (1)
Cordylocarpus (1)	Physorrhynchus (2)
Crambe (26)	Pseuderucaria (2)
Crambellia (1)	Pseudofortuynia (1)
Didesmus (2)	Psychine (1)
Diplotaxis (27)	Quezeliantha (1)
Dolichorhynchus (1)	Raffenaldia (2)
Douepia (1)	Raphanus (2)
Enarthrocarpus (5)	Rapistrum (2)
Eremophyton (1)	Rytidocarpus (1)
Eruca (3)	Savignya (1)
Erucaria (9)	Schouwia (1)
Erucastrum (19)	Sinapidendron (5)
Euzomodendron (1)	Sinapis (5)
Fezia (1)	Succowia (1)
Foleyola (1)	Trachystoma (3)
Fortuynia (2)	Vella (5)
	Zilla (1)

Within the tribe, Schulz (1919, 1923, 1936) also recognized, somewhat arbitrarily on the basis of morphological characters, seven subtribes: Brassicinae, Cakilinae, Moricandiinae, Raphaninae, Savignyinae, Vellinae, and Zillinae. Gómez-Campo (1980a) has since proposed a reduction to six subtribes with the inclusion of the Savignyinae in the Vellinae. The Brassicinae and Moricandiinae both include genera with elongated siliquose dehiscent fruit, while the other subtribes include those with reduced or "nucamentaceous" fruits.

Generic boundaries in the tribe are still somewhat arbitrarily drawn, and the establishment of clear-cut intergeneric relationships requires clarification. Unlike many of the small genera, the species are generally very distinct throughout the family, with fruit characters being the most reliably used structures for the proper identification of genera and species. Taxonomic debate in the tribe has centred most particularly upon the number of and relationships between the subtribes and genera (Hedge 1976, Al-Shehbaz 1985).

The genus *Brassica* is one of ten core genera in the subtribe Brassicinae, which also includes *Coincya*, *Diplotaxis*, *Eruca*, *Erucastrum*, *Hirschfeldia*, *Raphanus*, *Sinapidendron*, *Sinapis*, and *Trachystoma*. The Brassicinae is defined primarily on the basis of elongated (siliquose) dehiscent fruits, presence of median nectaries, and usually seeded beaks. Although morphologically quite distinct from subtribes Cakilinae, Vellinae, and Zillinae, its separation from the Raphaninae and Moricandiinae is less clear. Current generic circumscriptions within the subtribe Brassicinae have also been considered to be highly artificial by many taxonomists, with generic delimitation based primarily on only one or two morphological traits.

Systematists are continuing to re-evaluate relationships within the tribe Brassiceae by way of morphological, cytological, hybridization, isozyme and molecular analyses (studies reviewed in Warwick and Black 1991, 1993). Such research has confirmed many proposed species relationships, but has also indicated new relationships between genera and species. In particular, these studies have identified new potential sources of germplasm for *Brassica* crops, indicating that the range of germplasm important to the genus is much greater than previously recognized.

The following Guide to the wild germplasm of *Brassica* and allied crops (Tribe Brassiceae, family Cruciferae) will be divided into five parts as indicated below:

- I. **Taxonomy and Genome Status** - [Complete list of genera and species in the tribe and their genomic status, containing cross references for commonly confused names];
by S.I. WARWICK
- II. **Chromosome Numbers**;
by S.I. WARWICK & J.K. ANDERSON
- III. **Interspecific and Intergeneric Hybridizations**;
by S.I. WARWICK & L.D. BLACK
- IV. **Wild Species as Sources of Agronomic Traits** - [List of potentially useful agronomic traits and possible wild germplasm sources in the tribe];
by S.I. WARWICK
- V. **Life History Data** [Summary of habitat and geographical distributions of all species indicated in part I.]
by S.I. WARWICK

The information provided in this guide is intended to be useful in providing direction for future genebank needs for these crops and for assisting biotechnologists and breeders wishing to utilize these genetic resources in their research programs.

PART II: CHROMOSOME NUMBERS IN THE TRIBE BRASSICEAE (Cruciferae)

The following publication is the second part of a guide to the wild germplasm of *Brassica* and allied crops (Tribe Brassiceae, family Cruciferae).

This checklist contains the haploid chromosome numbers (n) for taxa of the tribe Brassiceae for which information is available. The compilation updates the list provided by Gómez-Campo and Hinata (1980). Since the latter publication, an additional 159 counts have been reported. Seven counts are reported here for the first time as Warwick, Black & Anderson (unpubl.). Counts are required for 45 of the 217 species and seven of the 51 genera [*Ammosperma*, *Dolichorhynchus*, *Douepia*, *Eremophyton*, *Henophyton*, *Pseuderucaria*, and *Quzelianthus*].

Progress in this field has been as follows:

	New counts	Accumulative
Several authors between 1916 and 1932	59	59
Several authors between 1933 and 1972	84	143
Several authors between 1973 and 1980	100	243
Several authors between 1981 and 1993	159	402

In the family Cruciferae a continuous series of base chromosome numbers from 4 to 13 exists (Al-Shehbaz 1984), with 37% of the species having a base chromosome number of 8 (range $2n = 8$ eg. *Physaria* spp. to $2n = 256$ *Cardamine* spp.). Approximately 37% of species in the family are polyploid. It is believed that aneuploidy (i.e. the gain or loss of individual chromosomes) and diminution in chromosome size have played a more important role in the evolution of the family than polyploidy.

Chromosome number has been particularly well documented within the tribe Brassiceae with 171 (79%) of the 217 species counted. Gametic chromosome numbers range from $n = 6$ in *Erucaria cakiloidea* to $n = 75$ in *Crambe gordjagini*. No single chromosome number appears to be dominant within the tribe. The gametic chromosome numbers 7, 8, 9, and 15 occur in 14-18% of the species, while 10, 11, and 12 occur at frequencies ranging from 6-9% (Al-Shehbaz 1985).

In the tribe, species with gametic chromosome numbers greater than 13 are believed to be polyploid (Gómez-Campo and Hinata 1980). Based on this premise, 37% of the 171 species counted should be polyploid. Half of the 51 genera would appear to contain some polyploid species. So far, the hexaploid level has been observed in four genera (*Boleum*, *Erucastrum*, *Moricandia*, and *Crambe*). Indeed, many genera (e.g., *Crambe*, *Moricandia*, *Vella*, *Boleum*,

Zilla, and *Euzomodendron*) appear to be entirely polyploid. In the genus *Erucastrum*, there is a continuous series from diploids to octoploids. Allopolyploidy has been reported in the tribe. The most familiar crop examples are *Brassica carinata* ($n = 8+9$), *B. juncea* ($n = 10+8$), and *B. napus* ($n = 10+9$), combinations of the basic chromosome numbers $n = 8, 9, 10$ of *B. nigra*, *B. oleracea*, and *B. rapa*, respectively. Three other natural allopolyploid taxa have also been reported: *Diplotaxis muralis* ($n = 11+10$), *Erucastrum elatum* ($n = 7+8$) and *Erucastrum gallicum* ($n = 7+8$). Aneuploidy is also proposed as having a profound impact on the evolution of *Diplotaxis*, *Brassica*, and other genera in the tribe (Al-Shehbaz 1985).

Chromosome number in diploid species of the genus *Brassica* varies from $n = 7-11$. On the basis of cytological studies, Röbbelen (1960) proposed $x = 6$ as the basic chromosome number of the genus *Brassica* and the above range in chromosome numbers an aneuploid series. However, molecular studies do not provide support for the ancestral status of $n = 7$, as it has been found to have multiple origins in separate lineages (Warwick & Black 1991, 1993). In addition, recent isozyme studies have shown evidence for genome duplication in some species with chromosome numbers as low as $n = 7-10$ (Quiros 1987, Warwick & Black 1993). This has led some researchers to suggest $x = 3$ as the basic chromosome number for the genus *Brassica* (Chen & Heneen 1991).

In the checklist below, taxa are arranged alphabetically and correspond to the taxonomic framework for the tribe indicated in part I of this guide.

A very faint, light gray watermark-like image of a classical building with four prominent columns and a triangular pediment occupies the background of the entire page.
