Assessment of the Nain Unit Arctic Charr Population in 1987
by
J. B. Dempson

Science Branch
Department of Fisheries and Oceans
P. 0. Box 5667

St. John's, Newfoundland AlC 5X1

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche $q u^{\prime} e l l e$ contient ne doivent pas être considérés comme des énoncés finals sur les sujets traitēs mais plutôt comme des rapports d'ētape sur les êtudes en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyē au secrētariat.

#### Abstract

Reported landings of Arctic charr from the Nain assessment unit totaled 46 t in 1987, essentially achieving the total allowable catch of 47 t . This represented $47 \%$ of the total catch of Arctic charr from the Nain Fishing Region in 1987. Catch was $24 \%$ higher than in 1986, while catch per unit effort was 14\% higher. Likelihood ratio statistics were used to examine temporal and spatial variation in the size composition of the catches from 1980 to 1987. Significant differences were found among years, inshore and offshore fishing zones, and specific time periods within the fishing season. However, no consistent trends have occurred in the mean length or age of catch since 1977, although mean size of the catch in 1986 and 1987 was smaller than in other years. Part of this difference could be related to the spatial distribution of fishing effort with more of the catch being taken in the offshore zone and generally later in the fishing season in comparison with earlier years. The 1977-79 year-classes represented $62 \%$ of the catch in 1987. A sequential. population analysis was carried out on catch-at-age data from 1977 to 1987 and suggested a reference level catch in 1988 from 41.1 to 48.5 t.

## RESUME

Les débarquements d'omble chevalier enregistrēs pour l'unité d'évaluation de la Nain ont totalisé 46 t en 1987, ce qui atteint presque le TPA de 47 t . Cette quantité représentait $47 \%$ du total des prises d'omble chevalier de la région de péche de la Nain en 1987. Les prises étaient de $24 \%$ supérieures à celles de 1986, tandis que les captures par unité d'effort ètaient en hausse de $14 \%$. Les statistiques sur le rapport de vraisemblance ont servi à examiner la variation spatiale et temporelle dans la composition par taille des prises de 1980 à 1987. On a observé des différences significatives d'une annēe à l'autre, entre les zones de pêche côtières et hauturières et entre des pēriodes données pendant la saison de pêche. Cependant, on n'a relevé aucune tendance stable dans la longueur moyenne ou l'âge à la capture depuis 1977, bien que la taille moyenne des captures en 1986 et 1987 ait été infërieure à celle des autres annēes. Cette différence peut s'expliquer en partie par la distribution spatiale de l'effort de pêche, car une proportion plus grande des prises a eu lieu dans la zone hauturière, et de façon génērale plus tard dans la saison de pēche que les années prēcēdentes. Les classes annuelles 1977-1979 reprēsentaient $62 \%$ des captures en 1987. L'auteur a effectué une analyse séquentielle de population sur les données concernant l'âge à la capture entre 1977 et 1987, et juge que le niveau de référence des captures en 1988 serait de 41,1 à $48,5 \mathrm{t}$.

## Introduction

The Nain assessment unit (Fig. 1) consists of an inshore zone made up of Anaktalik Bay, Nain Bay, Tikkoatokak Bay, and Webb Bay subareas, and an offshore island zone consisting of the Dog Island and Black Island subareas (Dempson et al. 1986). It was first assessed as a homogeneous unit in 1985 (Dempson and LeDrew 1986). Prior to this, individual assessments were conducted separately on Arctic charr populations from Nain-Tikkoatokak Bay and Anaktalik Bay. Annual landings from the Nain assessment unit have ranged from 34 to 76 t (mean $=54$ t) (Table 1) and from 1977 to 1987 have represented $36 \%$ of the total commercial production from the Nain Fishing Region. In 1987, 47\% of the commercial landings came from the Nain unit. The recommended TAC for 1987 was 47 t . This TAC was partially divided into specific inshore quotas of: Anaktalik Bay - 5.2 t ; Nain-Tikkoatokak Bay - 15.5 t ; Webb Bay - 8.4 t.

This paper summarizes results of the 1987 fishery and provides a forecast of available harvest, or reference level catch, for 1988.

## Assessment

## Catch and effort data

Catch and effort data for the Nain assessment unit are summarized in Table 1 for 1974-87. The highest catch of 76 t occurred in 1977, the lowest catch of 34 t was in 1975. The quotas listed in Table 1 for 1979-83 applied only to the specific subareas of Anaktalik Bay and Nain-Tikkoatokak Bay. In 1984 and 1985, an offshore component was included in the TAC. The quota area catch in Table 1 summarizes landings for those subareas specifically under quota restrictions only, prior to the derivation of assessment units in 1986. In 1986 and 1987, the TAC applies to the entire assessment unit.

Landings in 1987 totaled 46 t , essentially achieving the recommended TAC for this stock unit. This represented an increase of $24 \%$ over the catch in 1986. Effort increased by $8 \%$, while catch per unit effort (CUE) was $14 \%$ higher than in the previous year.

In 1987, $61 \%$ of the catch from the Nain assessment unit occurred in the offshore zone, continuing the trend for increased catch and abundance of fish (CUE) which began in the early 1980s. Table 2 summarizes the mean date of the fishery as estimated by a migratory timing statistic (Mundy 1982; Dempson and Kristofferson 1987). Based on either catch or catch per unit effort, data suggest that Arctic charr have been more abundant at sea later in the summer during more recent years (1983-87) in comparison with earlier years. Regression analyses were used to examine the relationship between catch, effort, and timing of the fishery (Table 3). During the past nine years (1979-87), a total of $87 \%$ of the variation in catch can be explained by the two variables of effort and timing; effort explained $71 \%$ of the overall variation while timing explained an additional $16 \%$. Years with earlier timing statistics generally coincided with higher landings of Arctic charr, a phenomenon which
has also been observed in catches of chinook salmon, Oncorhynchus tshawytscha, in the Yukon River, Alaska (Mundy 1982).

Variation in catches among years may also be a function of different catchability of fish as it relates to annual changes in the ocean migration patterns. Within the Nain stock unit it has been reported that of fish tagged and released within this unit ( $N=3707$ ), $97 \%$ of the subsequent recaptures ( $N=1268$ ) came from the same stock unit (Dempson and Kristofferson 1987). It was also noted, based on tagging data from 1982 to 1985, that fish from one particular subarea (Nain Bay-Fraser River) showed variable ocean migration patterns in different years. Using updated information from 1982 to 1987, the categorical data modeling procedure (Bishop et al. 1982; SAS 1985) now indicated that there is evidence to show that movement patterns at sea varied annually for both Nain Bay and Tikkoatokak Bay fish (Table 4). Differences in abundance of fish in specific subareas, as evidenced by CUE data, probably reflect a combined influence of changes in the distribution of fishing effort, variable movement patterns of fish, variability in the duration of fishing effort, as well as actual changes in stock abundance.

## Size distribution of commercial landings

Since 1980, approximately 57,000 fish have been sampled from the Nain assessment unit to obtain information on the size distribution of the commercial landings. Length-frequency sampling is also used to weight the information from an age-length key to obtain representative information on catch at age. The length-frequency data were examined to determine any heterogeneity of samples which could be related to the effect of commercial exploitation on the stock. Likelihood ratio statistics were used to examine temporal and spatial variability in the size distributions following the method employed by Baird et al. (1987).

Arctic charr were measured for fork length and recorded in two-centimeter intervals. The smallest fish measured over the past eight years (1980-87) were in the 36 cm interval ( $36.0-37.9 \mathrm{~cm}$ ), while the largest were from the 80 cm grouping. Analyses, however, were conducted on truncated data which excluded fish less than 42 cm in size and those fish which were in size categories 66 cm and higher. In total, $99.3 \%$ of all fish measured were within the $42-64 \mathrm{~cm}$ intervals. This truncation also removed the possibility of obtaining any zero values for expected cell counts.

There was a highly significant difference in the size distribution of catches between years ( $G=5650$, $\mathrm{df}=77, \mathrm{P}=0.000, \mathrm{~N}=56,473$ ). As indicated in Table 5, modal size of fish has changed from the 52 cm interval in 1980 and 1982 to 50 cm in 1983-85, and then to the 48 cm interval during the past two years. Mean lengths are also summarized in Table 5. Mean length has decreased, particularly during the past two years, but not consistently. Significant differences also exist in the size distribution of catches between the inshore and offshore zones $(G=1077, \mathrm{df}=11, \mathrm{P}=0.000, \mathrm{~N}=56,473$ ). Within the two zones there are also differences among years (Table 6). The fishing season was stratified into four time periods: June 15-July 14 , July 15 -July 31 , August $1-15$, and August 16 to the end of the season. There is
a tendency for mean length of the catches to decrease as the fishing season progresses for both the total assessment unit and for separate inshore and offshore zones (Table 7). This is consistent with the observation for size of fish entering local rivers to decrease with time (Dempson and Green 1985). Within individual time periods, the size distribution of catches differs between zones. In addition, there are also size differences between years when comparisons are made by individual zones and time periods.

Results from these analyses indicate significant variation in the length composition of catches between years, inshore and offshore zones, and among specific time periods during the fishing season. The decrease in the mean and modal size of the catch during the past several years may be due to a selective removal of larger fish from the population. However, it may also be related to the spatial distribution of fishing effort with a greater proportion of the catch now being taken in the offshore zone and generally later in the fishing season in comparison with earlier years. Thus it is important to obtain representative samples throughout the entire fishing season and from both inshore and offshore subareas if possible.

## Cohort analyses

Numbers at age were available since 1977 and are summarized in Table 8. Data were derived from annual commercial sampling programs. Mean age has ranged from 8.5 to 9.8 years with no consistent increasing or decreasing trend. On average, over $60 \%$ of the catch is made up of three age-classes of fish represented by 8-, 9-, and 10-year-01ds. The 1977-79 year-classes represented $62 \%$ of the catch in 1987.

Weights at age were calculated from commercial samples obtained from 1977 to 1987. Gutted head-on weights were converted to whole weight using the conversion factor 1.22 (Dempson 1984). For yield-per-recruit analysis, mean weight at age for the period 1977-79 was used, similar to previous assessments. For stock projections, mean weight at age for the period 1984-87 was used (Table 9).

Total mortality ( $Z$ ) was calculated using the Paloheimo method (Ricker 1975) and the average value from all years (1977-78 to 1986-87) was 0.55. The average $z$ for the past four years was 0.54 . Assuming a natural mortality rate of 0.2 yields an estimate of fishing mortality of about 0.35. An estimate of total mortality was also derived from a catch curve using catch per unit effort at age data from 1985 to 1987. This also indicated a $z$ of 0.55 .

As in past years, an estimate of fishing mortality was derived from:

$$
\mu=1-e^{-F}(\text { Ricker 1975) },
$$

where $\mu$ was estimated from tag recaptures. Using last year's value of $10 \%$ for an estimate of tagging mortality, tag loss or non-reporting of tags results in a value of $\mu$ of

$$
\mu=\frac{126}{374}=0.3369
$$

which translates into an estimate of fishing mortality (F) of 0.41 ( $95 \% \mathrm{CL}=$ 0.33-0.51).

An initial cohort analysis was run using partial recruitment values and terminal fishing mortality ( $F_{T}=0.4$ ) from last year's assessment (Dempson and LeDrew 1987). An iterative procedure was used to obtain estimates of $F$ for the oldest age group ( $F_{B}$ ) (Rivard 1982). Following this, partial recruitment rates were calculated using the historical averaging method from the matrix of fishing mortality rates generated by the cohort analysis using years 1981-85. These values were then applied to the value for terminal fishing mortality and the procedure repeated until the partial recruitment values stabilized (Table 9).

Yield per recruit was calculated by the method of Thompson and Bell (Ricker 1975) using partial recruitment rates and mean weight at age. $F_{0.1}$ was 0.40 at a yield per recruit of 0.89 kg .

Cohort analyses were run using a range of terminal fishing mortality rates from 0.2 to 0.7 . In each run, fishing mortality rates for the oldest age group $\left(F_{B}\right)$ were re-evaluated using the iterative procedure. Regressions of $F$ (weighted mean $F$ for fully-recruited fish) on fishing effort and mean mid-year population biomass on catch per unit of effort of fully-recruited fish were used in tuning the analysis to key in on an appropriate value for $F_{T}$ in 1987. Data from 1977 to 1987 were included in the regression analyses.

Regressions of $F$ on effort showed a decrease in the correlation coefficient with an increase in $F$ (Table 10). The residual from the last point (1987) to the regression line was smallest when $F_{T}=0.375$ while the intercept value was closest to 0 when $F_{T}=0.4$. The sum of the residuals for the last three years was the smallest when $F_{T}=0.6$, but the sum of squares of residuals for the last three years (1985-87) was the lowest when $F_{T}=0.35$ (Table 10).

With respect of the regressions of population biomass on CUE, the correlation coefficient had the highest value when $F_{T}=0.4$ (Table 10). The residual of the last year (1987) to the regression line was lowest when $\mathrm{F}_{\mathrm{T}}=$ 0.375, while the sum of the residuals or the sum of squares of residuals for the last three years (1985-87) was lowest when $F_{T}=0.4$

## Catch projections

Projections were run with $F_{T}$ varying from 0.375 to 0.45 . Recruitment for the projections was estimated from the geometric mean of population numbers for age 6- and 7-year-01d fish for years 1977-85. Weights at age were based on 1984-87 data. Table 11 summarizes the population numbers and fishing mortality matrix for the cohort analysis run with $F_{T}=0.4$.

Results of the projections are summarized in Table 12. The reference level catch in 1988 ranges from 41.1 to 48.5 t with the highest value occurring with $F_{T}=0.375$. Owing to the similarity in the 1987 recommended catch ( 47 t ) with the values projected with $\mathrm{F}_{\mathrm{T}}=0.375$ and 0.4 , it is suggested that the reference level catch of 47 t remain in effect for the Nain assessment unit in in 1988 with no additional changes to the individual quotas assigned to the inshore subareas of Anaktalik Bay, Nain-Tikkoatokak Bay, and Webb Bay.
