## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

#### Abstract

In 2018, the Maritimes Region of Fisheries and Oceans Canada will be undertaking a framework assessment of 4X5Y Atlantic Cod (Gadus morhua). Such assessments are intended to be a comprehensive review of the biology, stock structure, the fishery, abundance indices, current assessment methodology and approaches for determining acceptable harvest limits. This document explores a variety of data sources available for 4X5Y Cod, including tagging projects (1980s-2000s), commercial fishery information (1980-2017) and departmental research surveys (1983-2017). The results of stock structure analyses, spatial and temporal patterns in distribution, bycatch, biological attributes (length and weight at age, condition factor, growth and maturity) and updates to data inputs for stock assessment (fishery catch at age, survey indices of abundance, relative fishing mortality, total mortality) are also described here, as well as any persistent data gaps. Finally, a preliminary review of ecosystem indicators and accompanying data considered relevant to the 4 X 5 Y Cod assessment is summarized.

## INTRODUCTION

Atlantic Cod (Gadus morhua) have a broad distribution in the western Atlantic, ranging from Cape Hatteras to the coast of Greenland. Cod on the Southern Scotian Shelf and Bay of Fundy in Northwest Atlantic Fisheries Organization (NAFO) Divisions 4X and Canadian portion of 5Yb have been managed as a single unit since 1985 and are jointly referred to as 4X5Y Cod. The last full assessment for this management unit was conducted in 2008 (Clark and Emberley 2009), followed by a Recovery Potential Assessment (RPA) in 2011, which concluded that this stock was in the critical zone (Clark et al. 2015). This research document is intended to provide an update on several biological and fishery attributes and constitutes the first part of a 4X5Y Cod Framework Review scheduled for 2018-2019.

## FRAMEWORK REVIEW AND OBJECTIVES

The objectives for the Framework Review meeting are to review the data inputs for 4X5Y Cod, as well as the model(s) used to determine stock status, reference points, risk analysis and the inter-framework assessment strategy. There will be two parts to this process:
Part 1 - Review of Fishery Data Inputs and Indices of Abundance (March 2018):

- Review definition of the 4X5Y Cod management unit (growth, morphometrics, movement).
- Review 4X5Y Cod fishery distribution, landings, age composition, timing and bycatch.
- Review Research Vessel survey age-specific indices of abundance, weight/length at age, condition, spatial distribution, age composition, recruitment, survey $Z$ and maturity.
- Examine sources of ecosystem information (environmental factors, diet information, unaccounted for sources of mortality, etc.).

Part 2 - Assessment of Model(s) to determine stock status, reference points, risk analysis and the inter-framework assessment strategy (October 2018)

## BACKGROUND

## STOCK STRUCTURE IN 4X5Y

Atlantic Cod (Gadus morhua) have a broad distribution in the western Atlantic, ranging from Cape Hatteras to the coast of Greenland. It is found in several concentrations along the Canadian Atlantic coast, including the Southern Scotian Shelf and the Bay of Fundy in Northwest Atlantic Fisheries Organization (NAFO) Divisions 4X and the Canadian portion of 5Yb (Figure 1). Cod in these two areas have been managed as a single unit since 1985 and are henceforth jointly referred to as 4X5Y Cod.

Spawning of Cod is distributed geographically throughout the 4X5Y area. In the spring, spawning occurs primarily on Browns Bank, with some fishermen reporting spawning fish in the waters off Digby Neck and Grand Manan (Behnam and Trippel 1998). Egg and larval studies support these findings, with eggs found in high concentrations on Browns Bank and more generally distributed throughout the Bay of Fundy in the spring (Neilson and Perley 1996). The fall spawning event takes place between October and December, and is generally restricted to the inshore waters of Nova Scotia (Neilson and Perley 1996). Although detailed historic accounts of spawning fish around Halifax Harbour, Sambro Head and St. Margaret's Bay exist (McKenzie 1940), recent reports of spawning fish in the area are sparse (Clark and Emberley 2009). Lack of recent, detailed information on the fall spawning event represents a major data gap for interpreting the stock structure of Cod within the 4X5Y management unit.

Although assessed together, Cod in the Bay of Fundy (NAFO areas 4Xqrs5Yb) and Scotian Shelf (NAFO areas 4Xmno) areas of the management unit exhibit distinctly different growth rates (Figure 2). Cod from the Bay of Fundy region (henceforth referred to as western fish) have a higher growth rate, reaching an average length of 77 cm by age 5 , while those from the Scotian Shelf (henceforth referred to as eastern fish) attain an average length of 65 cm at age 5 (Figure 2). Instantaneous rates of growth at age (length/age) from the summer RV survey data show the transition in distribution of fast growing fish found throughout the Bay of Fundy region, to the slower growth seen along the Scotian Shelf (Figure 3). Some movement between these areas is bound to occur, but only fish caught in NAFO area 4Xp consistently exhibit characteristics of both growth curves throughout the time series (Figure 4). Although the exact extent of mixing within 4 Xp has not been quantified, it is considered a mixing area for eastern and western Cod within the 4X5Y management unit.

The degree to which fish mix within the whole 4X5Y management area varies seasonally and is not uniform across the region. Tagging studies generally showed that fish tagged in the Bay of Fundy were predominantly recaptured within the bay during the fall, whereas those recaptured in the spring moved southward towards the Gulf of Maine, Georges Bank (5Z) and Browns Bank (4Xp) (Clark and Emberley 2009). Cod tagged on the Scotian Shelf (Roseway, LaHave and Baccaro banks, 4Xmno) were recaptured in much closer proximity to the release locations, with few recaptured west of Browns Bank (4Xp). While Cod tagged in the Bay of Fundy and those tagged on the Scotian Shelf exhibit little intermixing, Cod tagged on Browns Bank ( 4 Xp ) were recovered broadly in both areas (Campana and Simon 1985, Hunt et al. 1999, Clark and Emberley 2009). Results from these tagging studies are consistent with having two stock components within 4 X 5 Y , along with a mixing area in 4 Xp (Browns Bank), but do not provide insight into the actual rates of mixing within 4X5Y (Figure 5).

Tagging studies also found some movement occurring from 4X5Y into adjacent areas. Cod tagged on Browns Bank moved south onto Georges Bank while Cod released on the north-eastern portion of Georges Bank (5Zej) exhibited a reciprocal movement into the Bay of Fundy and Georges Basin; Cod tagged on the south-eastern portion remained on Georges Bank or moved south towards Cape Cod (Hunt et al. 1999, Clark and Emberley 2009, O'Brien and Worcester 2009). Although conventional tagging studies can identify possible linkages between adjacent management areas, the extent of mixing is difficult to quantify, as results are often influenced by fishing effort distribution, tag release location and timing of release/recapture (O'Brien and Worcester 2009). In addition, the rate of mixing between the areas seems to vary with time, as the growth relationship for Cod on eastern Georges Bank (5Zjm) used to resemble that of Bay of Fundy fish prior to 1994, but has shifted closer to that of Scotian Shelf fish since then (Figure 6).
In general, a two stock component structure within 4X5Y seems to persist, with a mixing area in 4Xp and some movement taking place between adjacent management areas. Additional work, particularly in the field of genetics, would be highly beneficial in improving the understanding of the Cod population structure in this area. Finally, given this two-stock component structure within the 4X5Y Cod management unit and assuming no broad mixing between the two stock components, a concentration of fishing effort in one area could lead to overexploitation of a single component, while leaving the other unharmed. Management of the fishery should be conducted in a fashion which aims to avoid over-exploitation in any part of the 4X5Y stock area (Clark et al. 1998).

## HISTORY OF THE 4X5Y FISHERY

Prior to 1962, Cod in NAFO area 4X were caught as part of an inshore fishery prosecuted primarily by small Canadian vessels using handline and longline gears (Figure 7). In 1962, both

Canadian and foreign otter trawlers began fishing heavily on Browns and LaHave banks, quickly increasing Cod landings from < 15,000 t per year to 35,500 t per year (Figure 8). Although no quota was set for Cod at this time, Haddock quota was imposed on the mixed groundfish fishery around 1970 which led to a reduction in fishing effort and a steep decrease in Cod landings followed in subsequent years (Figure 8). This decrease was further emphasized by the closure of Browns Bank to fishing in March and April of 1970.

Total Allowable Catch (TAC) for Cod in 4X was first set in 1975, but only applied to the offshore portion of 4 X , as Browns and LaHave banks were thought to be a discrete stock. However, the impact of this offshore TAC on 4X Cod landings was limited, due to misreporting of catches as adjacent 4X inshore areas which did not have a TAC (Gagne et al. 1983). Following a rapid increase of 4X Cod landings from 1976 to 1981, a TAC of 30,000 t was imposed on the whole 4 X management area. This resulted in a spike in misreporting of 4 X catches as 5 Y in subsequent years (Figure 9). The TAC on 4X Cod was held constant until 1985, when 4X5Y Cod was first assessed as a single stock (Figure 8). Following this assessment, 4X5Y Cod quotas quickly became more stringent, leading to both underreporting of landings and misreporting of landed Cod as other species, particularly in 1987 and 1988 (Campana and Simon 1987, Campana and Hamel 1990). In response, enforcement efforts increased, mandatory weigh-outs were established (1990) and data accuracy improved (Campana and Hamel 1992, Gavaris 1993).

The 1990s were a period of drastic quota changes, increasing to a maximum of $26,000 \mathrm{t}$ in 1991, dropping to $9,000 \mathrm{t}$ by 1995, and decreasing even further after 1997 (Figure 8). Although total fishing effort in 4X5Y declined accordingly across all gear sectors, the decline was concentrated on the Scotian Shelf portion of 4X5Y, with gillnet and otter trawl effort in the Bay of Fundy remaining stable throughout the 1990s (Clark et al. 1998). This redistribution of fishing effort into the Bay of Fundy was attributed to a combination of changing management measures (e.g., area-time closures), the industry's need to balance quotas and an apparent shift in resource distribution (Clark et al. 1998).
A rebuilding strategy was adopted for 4 X 5 Y Cod in 2000, and quota was maintained at $6,000 \mathrm{t}$ for four years (Table 1). Groundfish directed effort (Cod, Haddock and Pollock) for the mobile fleet remained focused on the Bay of Fundy throughout the early 2000s, but shifted almost entirely to Haddock directed trips (Clark and Hinze 2003). Inshore catch rates began to decline in 2003, forcing inshore fixed gear fishermen further offshore, but most other groups continued to catch their quota (Clark and Hinze 2003). Between 2004 and 2008, Cod landings fell well below quota, with many participants targeting other species and reserving Cod quota as bycatch (Clark and Emberley 2009). As quota continued to decrease into the 2010s, the proportion of Cod directed trips (>50\% of landed weight is Cod) in the mixed groundfish fishery decreased across all gear types and Cod became primarily a bycatch species (Figure 10; Table 2). The most recent quota decrease took place in 2014, with TAC reduced by $50 \%$ to a total of $1,650 \mathrm{t}$ over two years (2015-2016 and 2016-2017) and this arrangement was renewed for the 2017-2018 and 2018-2019 quota years (Table 1).

## HISTORY OF THE 4X5Y ASSESSMENT

The treatment of inshore and offshore Cod stock components in 4X5Y as a single unit for assessment purposes commenced in 1985 (Campana and Simon 1985). The increasing range capability of the fleet made the apportioning of landings to inshore or offshore, on the basis of tonnage class, unreliable. Furthermore, the results from tagging of Cod on Browns Bank in spring suggested substantial mixing between inshore and offshore components, as well as among inshore spawning groups. Consequently, it was felt that separate assessments of
inshore and offshore components of 4X5Y were no longer appropriate (Campana and Simon 1986).

Growth differences between eastern (Scotian Shelf) and western (Bay of Fundy) fish were first incorporated into the 4X5Y stock assessment in 1994 (Clark et al. 1995). Shortly after, a variety of model formulations for the 4X5Y Cod stock were explored, including changes in survey catchability ( $q$ ), natural mortality (M), and separate assessments for Bay of Fundy and Scotian Shelf stocks, but none seemed to adequately capture the variability in the data (Clark 1997, Clark and Paul 1999). The attempt at modeling two stocks separately showed no significant difference from modeling them together, suggesting that recruitment patterns were very similar in the two areas (Clark 1997). These results may, however, have been confounded by the degree of mixing of Cod between these areas.

Eventually, a single model formulation was accepted (Clark et al. 2000) but displayed a strong retrospective pattern and was rejected in 2003, leaving the 4X5Y stock without a formal assessment model until 2008. Several models investigating a change in survey catchability, change in natural mortality and exclusion of the Individual Transferable Quota (ITQ) survey were again examined during the 2008 assessment (Clark and Emberley 2009). The accepted model assumed no change in survey catchability, estimated an increase in M from 0.2 to 0.76 on older Cod (ages $4+$ ) since 1996, and excluded the ITQ survey from the assessment (Clark and Emberley 2009). Since then, multiple stock status updates have been provided, summarizing DFO Summer Research Vessel and fishery landing data to date (DFO 2016, DFO 2017).

A Recovery Potential Assessment (RPA) for 4X5Y Cod was carried out in 2011 to provide the information and scientific advice required to meet requirements under the Species at Risk Act (SARA). This process used data from the 2008 assessment (1980-2008) and concluded that the 4X5Y stock was in the critical zone (Clark et al. 2015).

## FISHERY

Atlantic Cod are captured as part of a multi-species groundfish fishery in NAFO areas 4 X and Canadian portion of 5 Yb . A recreational fishery for Cod also exists within this management area, but catches are not currently recorded.

## DATA QUALITY

As with many fisheries, data quality is a crucial part of the assessment process, and efforts to improve the collection, verification and processing of data are constantly ongoing. Use of pre-1980 catch data is limited to total amounts, as catch sampling prior to 1980 excluded the Bay of Fundy region, rendering any age or size stratification of the catch within the 4X5Y area inaccurate prior to 1980. The institution of Cod quotas in 1982 led to misreporting of catches into NAFO area 5 Y , as well as a decrease in the voluntary reporting of landings in a specific region of $4 X$, causing a spike in landings in 4Xunspecified (4Xu; Figure 9). In general, landings by NAFO sub-area are considered reliable since the institution of mandatory weigh-outs in 1990 (Campana and Simon 1987, Campana and Hamel 1990, Gavaris 1993). The issue of misreporting throughout the 1980s necessitates the assessment of 4X5Y Cod as a single unit; assessing Bay of Fundy and Scotian Shelf Cod separately would require additional work to address misreporting throughout the 1980s, or a time series starting post 1990. Since then, data quality has continuously improved, though anecdotal reports of misreporting of Cod catches were noted throughout 2000 and 2001 (Clark et al. 2002, Clark and Hinze 2003). The extent of the unreported catches was unknown, but they were thought to be considerably less than the reported landings at the time.

## FISHERY SAMPLES

The annual age-length key applied to the 4X5Y catch at length has been based on 750+ aged otoliths every year (Table 5). The collected otolith samples are selected for ageing based on having a broad length distribution, timing (quarter) and gear type. The otoliths for 4X5Y Cod have been aged by the same ager since 1988, with ager validation completed annually. The most recent evaluation (2017; 215 otoliths aged) resulted in a $90.7 \%$ agreement, with a CV of $2.37 \%$ and no indication of bias (Figure 11). The aged samples are aggregated by area and quarter; quarters 1 and 2 (Q1, Q2) do not exhibit distinct differences in age at length and are combined into half 1 (H1; Table 5).

Dockside monitors also sample groundfish trips for length composition of the catch. Length samples are grouped in the same manner as the otolith samples (area, gear and quarter), with small samples ( $<50$ fish measured) excluded from the analysis. Although efforts are made to achieve representative sampling for all groupings every year, in reality the catch sampling program is not set up for random sampling, so representativeness can be undermined by port sampler availability, proximity to port or even processing plant.

Separation of length and age samples by area is intended to account for growth differences between western ( 4 X qrs 5 Yb ) and eastern ( 4 Xmno ) fish. Cod in 4 Xp are considered a mixture of the two stock components and catches, have been historically separated based on a line which roughly follows the 90 fathom depth contour and loosely mirrors the strata used for each area in the RV survey (Figure 1). Fish from shallow water in the eastern part of 4 Xp are grouped with the Scotian Shelf landings, while those from deeper waters of 4 Xp are grouped with landings from the Bay of Fundy. If currently ongoing genetic studies improve understanding of stock delineation within 4X5Y, the method of splitting catches within 4Xp would need to be revisited.
Separation of length samples by gear is intended to account for differences in size catchability for different gear types (Table 6). In recent years, sampling of the gear types has become more unbalanced, with longline sampling intensity being half that of otter trawl, despite roughly equal proportion of annual landings by each (Table 3). Although efforts to balance port sampling effort by gear type in accordance with relative catches are made, gradual downsizing of the sampling program (e.g., decrease from six full time port samplers to one) make this goal logistically difficult to achieve.
The seasonal length-weight parameters used in deriving catch numbers at age were calculated by Campana and Hamel (1992) from seasonal survey data between 1978 and 1985 (Table 13). These parameters have been used since 1985 and continue to be appropriate, as there is no long-term trend in condition for 4X5Y Cod (Figure 32).

## LANDINGS AND CATCH DISTRIBUTION

Historically, Cod have been caught in 4 X 5 Y as part of a multi-species fishery by a variety of fleets using mobile gear (e.g., otter trawl) and fixed gear (e.g., handline, longline and gillnet) (Table 3). Reported bycatch of other species on Cod-directed (>50\% Cod catch by weight) trips was summarized by species, year and major gear type (Table 7, Table 8). For mobile gear, Haddock, Pollock and Winter Flounder have been the prevalent species, with a drastic decrease in Cod directed trips evident in recent years (Table 2, Table 7). For fixed gear, the decrease in Cod directed trips is more gradual, with Haddock, Cusk and Halibut making up the majority of bycatch species (Table 2, Table 8).
Currently, Cod in 4X5Y are landed primarily by the Fixed Gear < 45' and the Mobile Gear < 65' fleets, with smaller contributions by the Fixed Gear 45'-65' (Table 9). Landings by vessels from the other fleets (Fixed Gear > 65', Mobile > 65', First Nations and Offshore) do not meet the

Confidentiality Guidelines for Fisheries and Oceans Canada and therefore cannot be reported here individually.

Fixed gear fishing activity takes place mostly between June and December, and has generally been distributed throughout NAFO areas 4Xmnopq (Figure 13). Since 2014, catches of Cod by fixed gear have shifted out of 4Xp, but remain distributed throughout 4Xmnoq (Figure 14). Longline catches take place primarily in shallow waters off the south-western coast of Nova Scotia early in the season, and then expand outward on to the Scotian Shelf as the season progresses (Figure 13). The Pollock-directed gillnet fishery is responsible for the majority of fixed gear Cod catches in 4Xq, occurring mostly in the eastern portion of Jordan Basin throughout July and August (Figure 13). Handline catches have decreased throughout 2000s (Table 3), and currently only occur sporadically throughout the management unit.

Catches of Cod from mobile gear occur year round and are generally constrained to the western portion of the management unit (Georges Basin, Crowell Basin, Jordan Basin and the Bay of Fundy) (Figure 15, Figure 21). Similar to fixed gear, catches of Cod by mobile gear on Browns Bank (eastern portion of 4Xp) have all but disappeared since 2014 (Figure 16).

Historically the proportion of Cod landings from the Scotian Shelf has been greater than those from the Bay of Fundy, but the proportions switched with the redistribution of fishery effort in the late 1990s and early 2000s. More recently, the contributions from the two areas have become equivalent (Table 4; Figure 12). The contribution of landings from 4Xp was relatively low (approximately 10\%) during the 1970s and 1980s, but increased steadily to account for $30 \%$ of the 4X5Y Cod landings in the late 2000s (Figure 12).

Longline and otter trawl gears tend to catch Cod of similar size, with length frequencies peaking between 50 and 60 cm for both gears across all areas of the 4X5Y management unit (Figure 17). In contrast, gillnet tends to catch larger Cod, reflecting the selectivity of the 5.5" mesh size, with size frequencies peaking between 65 and 70 cm (Figure 17).

## CATCH AT AGE

Catch at age for 4X5Y Cod is calculated by applying the seasonal length-weight relationships to port and observer measured length ( 3 cm bin) frequency samples to obtain an estimated weight for each sample. The estimated sample weights are raised to the total commercial landed weight within gear, quarter and area, giving an estimated length frequency for the commercial catch within those groupings. Seasonal age-length keys are then applied to the length frequencies to obtain an age composition for the commercial catch.
Cod landings reported from 4Xu (unspecified area) were split between Scotian Shelf and Bay of Fundy components according to gear type, quarter, year and homeport. Landings reported in NAFO area $4 X p$ were divided into Scotian Shelf and Bay of Fundy components using their reported location. Historically, the line depicted in Figure 1 has been used to split 4 Xp catches, but recent redistribution of fishery catches is increasing the influence of this line. If single stock models are to be applied, alternative methods for delineating the two stocks should be investigated (e.g., genetics). Conversely, a multi-stock model which allows for mixing between the eastern and western fish can be used, assuming the extent of mixing in 4 Xp is investigated.

Fishery catch at age (CAA) for Cod in 4X5Y has been undergoing a consistent truncation in age structure since the 1990s, until 2014 when age 6 Cod were barely detectable and ages 8+ were completely absent (Table 14; Figure 18). There has been some reappearance of these older fish in the 2016 CAA, with both the Bay of Fundy and Scotian Shelf fisheries seeing a number of age 6 and 7 fish, but the number of older fish remains very low. The adjacent Cod stock on

Eastern Georges Bank (5Zjm) has experienced a similar trend in fishery CAA (Martin et al. 2017).

Throughout the 2000s, fishery catch was predominantly composed of Cod aged 3 through 5, with small contributions of Age 2 and 6 fish (Table 14; Figure 18). In 2016, however, contributions of Age 2 and 3 fish have decreased substantially on the Scotian Shelf (Figure 19). This drastic disappearance of young fish from the commercial CAA is unusual, as they are still being caught in the Research Vessel (RV) summer survey (Figure 37). Contradictory trends in the commercial and survey CAA can result from a change in the way the fishery is being prosecuted. A geographical redistribution of fishing effort, such as a recent shift out of 4Xp, could avoid grounds with younger fish and reduce their susceptibility to fishing activity. However, this shift occurred in 2014; two years before the disappearance of small fish from the Scotian Shelf CAA. Changes in management measures could also be responsible for diverging trends in commercial and survey CAA, but the most recent reduction in quota (DFO 2017c) were implemented in 2015, not 2016. Finally, a lack of small fish in the fishery CAA could be indicative of discarding and this possibility is examined in the Observer Data section below.

## WEIGHT AT AGE

Weights at age (WAA) for commercial landings in 4X5Y have shown divergent trends for different ages. Younger fish (ages 2 and 3 ) have experienced a steady increase in weights at age throughout the entire time series (Table 15; Figure 20). Given the declining presence of older fish in recent years, commercial fishery weights for fish ages 7 and above were not considered reliable.

Commercial weights at age for ages 4 through 6 decreased between 2003 and 2007, particularly in the Bay of Fundy, and the difference in weight at age between the two regions became notably smaller thereafter (Figure 20). This apparent convergence of weights at age between eastern and western fish becomes more pronounced with age and more closely resembles that of the eastern fish. Although this effect could be caused by a variety of factors (e.g., redistribution of fishery effort, influx of eastern fish into the Bay of Fundy, etc.), the actual cause is likely fishery-dependent, as survey weights at age do not exhibit the same convergence.

## OBSERVER DATA

Annual observer coverage for 4X5Y Cod can be calculated based on landings (observed landed weight of Cod / total landed weight of Cod) or trip (number of observed trips landing Cod / total trips landing Cod) for the three observed gear types (i.e., mobile, longline and gillnet) and a total estimate across these gears. Although observed trips can be further subdivided by target species (e.g., Redfish, Cod/Haddock/Pollock, Halibut, etc.), the commercial database does not record this information, limiting the observer coverage estimate for trips catching Cod to broad gear groups. The only exceptions are Redfish and silver hake directed trips, which can be isolated based on a combination of gear type (otter trawl) and mesh size ( $\leq 60 \mathrm{~mm}$ for Silver Hake and 65-130 mm for Redfish). Consequently, observer coverage was estimated for all trips within 4X5Y which landed Cod since 2003, and then further split into the following gear categories:

- Mobile gear $\leq 65 \mathrm{~mm}$ mesh size; includes Silver Hake directed trips.
- Mobile gear 65-130 mm mesh size; includes Redfish directed trips.
- Mobile gear $\geq 130 \mathrm{~mm}$ mesh size; includes Cod/Haddock/Pollock and flatfish directed trips.
- Fixed gear (longline); includes Halibut, White Hake and Cod/Haddock/Pollock directed trips.
- Fixed gear (gillnet); includes White Hake and Cod/Haddock/Pollock directed trips.

Observer coverage for the groundfish fishery remained below 2.5\% until 2009, when a three-year Species at Risk Coordination Espèces en Péril (SARCEP) bycatch project enhanced it to $5-7 \%$ (Table 10, Table 11). Although coverage across the groundfish fishery returned to low levels immediately following the completion of the SARCEP project, it has steadily increased since then and is currently estimated at 5-7\% (Table 10, Table 11). The coverage has been disproportionally higher for the mobile fleet, often doubling that of longline gear for both landings and trips (Table 10, Table 11). Observer coverage of the gillnet fishery remains at $0 \%$ in 4X5Y, as priority for coverage within the gillnet fishery is given to the 5Zjm management unit (H. Stone, Observer Program, pers. communication).

The recent disagreement of survey and commercial CAA on abundance of young fish (age 2 and 3 ), coupled with restrictive Cod quotas, could be indicative of discarding. However, comparison of length frequencies from observed and unobserved trips shows no indication of discarding of small fish since 2012 (Figure 22). A more in-depth analysis investigating the occurrence of discarding in the groundfish fishery would require higher and more representative observer coverage.

## DISCARDS

Discarding of Cod from the groundfish fishery is not permitted, and no discard estimate is routinely calculated or reported. Clark et al. (2015) estimated discards for a variety of species caught in the groundfish, Redfish and Sculpin fisheries, but these estimates were intended for broad comparisons across fisheries and years, and not as conclusive discard values. In addition, apparent reporting of Cod discards on observed trips in a fishery, where discarding of Cod is illegal, points to possible inconsistencies in what constitutes a discard. Low and often unrepresentative observer coverage, coupled with decreasing Cod abundance, continue to be the main hurdle for assessing the occurrence of discards in the 4X5Y groundfish fishery (Gavaris et al. 2010, Clark et al. 2015).
Cod are a demersal species, and would therefore be expected to interact with most fisheries using bottom gear in 4X5Y. However, observer coverage for these fisheries is either absent, too low or not representative, rendering discard estimates unreliable (Gavaris et al. 2010). Attempts to augment observer coverage for three principal 4X5Y fisheries (groundfish, inshore Scallop and Lobster) through a SARCEP program took place between 2008 and 2011. For the inshore Scallop fishery this resulted in observer coverage in Scallop Fishing Area (SFA) 28 for the first time, and a slight increase in existing coverage in SFA 29W (Figure 23), though the combined coverage for these areas was still relatively low (3.7\% and 4.2\% in 2008 and 2009, respectively; Sameoto and Glass 2012). For the Lobster fishery, the augmented observer coverage under the SARCEP program amounted to $0.2 \%$ of landings observed in Lobster Fishing Areas (LFA) 33 and 34 over two years, with substantial concerns raised about the quality of the data being collected (Figure 24; DFO 2011, DFO 2017, Pezzack et al. 2014). Cod discards have also been recently estimated for the 4X portion of LFA 41, which covers the shelf edge portion of 4 Xn and 4 Xp , but concerns regarding the bias of the observer coverage remain (Cook et al. 2017). Cod discard estimates from the principal 4X5Y fisheries above are summarized in Table 12, but use of these values for anything but broad comparisons across fisheries is not advised.

Despite several attempts to bridge knowledge gaps identified by Gavaris et al. (2010), insufficient levels of observer coverage and lack of systematic, unbiased sampling continue to be the major impediments to quantifying the magnitude of Cod bycatch in non-groundfish fisheries. Substantial, unaccounted-for removals from a population would be problematic for
most assessment models, so model-based ways of accounting for unreported sources of fishing mortality will be explored during the 4X5Y Cod modeling framework (Fall 2018).

## SURVEY

The annual bottom trawl Research Vessel (RV) survey has been conducted since 1970 and covers a substantial portion of the 4X5Y Cod management unit. Survey coverage is restricted to depths of > 15 fathoms in Bay of Fundy and > 50 fathoms off southern Nova Scotia, except for an area north of Browns Bank, which is not surveyed due to un-trawlable bottom. The survey is based on a stratified random sampling design, with 244 stations allocated to 57 strata. The survey uses a bottom trawl with a 19 mm Cod end liner and samples both fish and invertebrates for distribution, abundance, biological condition and stomach contents within the 4VWX5 area. Sampling is generally conducted during the summer season (June-August), but periodical spring sampling (February-March) has taken place in 4X5Y as well. Additional detail on survey coverage and sampling is available in DFO 2016.

The RV survey has undergone several vessel and gear changes throughout the time series, but problems during comparative fishing between RV Lady Hammond to the RV Alfred Needler in 1983 and uncertainties about the relative fishing power of the two vessels resulted in unreliable Cod conversion factors (Clark and Brown 1996, Mohn 1999). Without reliable conversion factors, abundance and biomass trends prior to 1983 are not comparable to subsequent years and have therefore been excluded from population models of 4 X 5 Y Cod. Fish biology data (e.g., condition, maturity, etc.) are independent of vessel effects and can continue to be reliably compared throughout the survey time series (1970+).
The Individual Transferable Quota (ITQ) Survey conducted by Industry vessels took place between 1996 and 2011, and consisted of a fixed station design (Claytor et al. 2014). In general, the ITQ survey had higher coverage of inshore areas along the coast of Nova Scotia, but less coverage along the New Brunswick coastline or within deeper waters along the Scotian Shelf. Following several in-depth evaluations of the ITQ survey data, it was concluded that data from this survey did not improve model fit or change the current perception of stock dynamics, so it continues to be excluded from 4X5Y stock assessments (Clark and Emberley 2009, Claytor et al. 2014).

## DISTRIBUTION OF CATCHES

Prior to 1994, catches of Cod from the RV summer survey were distributed throughout the Bay of Fundy, across the southern portion of the Scotian Shelf and along the Shelf edge (Figure 25). This spatial distribution persisted into the 2000's, though a general decrease in weight per tow of Cod was seen in all areas (Figure 26).
Since 2005, some notable shifts in summer distribution have become evident. Cod in the Bay of Fundy, previously distributed throughout the entire Bay area, have receded away from the coast and are now found primarily in deeper waters at the mouth of the bay, between Grand Manan and Digby Neck (Figure 27). Cod along the Scotian Shelf have all but disappeared from the Shelf edge, and are now concentrated almost exclusively on the banks (e.g., Browns, Lahave, Roseway, Baccaro, etc.) (Figure 27).

## LENGTH FREQUENCIES

Since the 2008 assessment, catches at length of Cod from the RV survey have generally been below the long-term mean for all years and areas, except for fish below 20 cm which were at or above the long term mean (Figure 28, Figure 29). The abundance of small fish ( $<10 \mathrm{~cm}$ ) was particularly notable in 2013, with both the Bay of Fundy and Scotian Shelf components showing signs of a strong incoming year class. Interestingly, similar trends were noted for the 4X5Y Haddock stock, with the 2013 year class moving on to become the strongest on record for that stock (DFO 2017g). Unlike Haddock, however, the initial signs of strong recruitment for Cod did not materialize as high abundances of larger fish in subsequent years (Figure 28, Figure 29).

Another notable occurrence since the last assessment was an unusually high abundance at most lengths of eastern fish in 2009 (Figure 29). As this high abundance did not persist in subsequent years and no biological or environmental explanation could be found, it was attributed to a survey year effect.

## WEIGHT AT AGE, SIZE AT AGE AND CONDITION

Weights at age (WAA) of Cod from the RV summer survey highlight the known divergence in growth rates between the two areas (Figure 30). Younger fish (ages 1 through 4) continue to exhibit the divergence in weight at age by region, with western fish experiencing a steady increase in weight at ages 1,2 and 3 throughout the 2000s (Figure 30). A similar trend in the commercial weights at age indicates that the two population components continue to exist with relatively little mixing of younger fish between the regions (Figure 20). In contrast to the commercial catch, weights at age for four year old fish caught on the survey do not converge throughout the 2000s, indicating that rates of mixing have not changed substantially between the two components (Figure 20, Figure 30). The intermittent presence of ages $5+$ in the survey catch, particularly for the Bay of Fundy region, makes it difficult to discern trends on older fish.
Lengths at age for 4 X 5 Y Cod from the RV summer survey are stable for both regions, with increased inter-annual variability on older fish in recent years, due to their decreasing abundance (Figure 31). Lack of discernible trend in lengths at age over the whole time series also underlines the consistency of ager performance for this stock since 1970.
Average Fulton's K, a measure of fish condition calculated as weight over length cubed, has generally been higher for western fish than for those from the Scotian Shelf (Figure 32).
Throughout the time series, this measure of condition seems to fluctuate without trend within both stock components (Figure 32). Since trends in Fulton's K throughout the time series could be obscured by significant changes in age structure within each stock component, an alternative measure of condition was also calculated by dividing the average weight at length for a given year by the average weight at length for all years (Figure 33). No obvious changes in condition at size were evident throughout the time series.

## MATURITY

Maturity data for 4X5Y Cod come exclusively from the RV spring survey, as Cod are not sampled for maturity during the summer cruises for logistical reasons. In addition, the spatial coverage of the spring survey was limited to NAFO area $5 Z$ (Georges Bank) in the late 1980s, effectively excluding 4 X 5 Y from the spring survey altogether. Although coverage expanded again in 2008 to include areas outside of 5 Z , coverage of NAFO 4 X 5 Y has been sporadic as Georges Bank remains the area of priority for the spring cruise. Consequently, the maturity data for 4X5Y Cod is intermittent, and had to be grouped into two broad time periods (pre and post 2000) to obtain a sufficient sample size for analyses (Table 18).

Length at $50 \%$ maturity has decreased slightly within the 4 X 5 Y management area, dropping from 43 cm to 37-39 cm for both stock components (Figure 34). Age at 50\% maturity shows a slight decrease as well, dropping from 2.5 to 2.2 years in the Bay of Fundy and from 3 to 2.8 years on the Scotian Shelf (Figure 35). In both cases, the age at 50\% maturity remains between 2 and 3 years of age, so use of ages 3 and older as spawning stock biomass remains appropriate for this stock.

## INDICES OF ABUNDANCE AND BIOMASS

The total biomass index for 4X5Y Cod has been steadily declining since the 1990s, but appears to have stabilized at a low level since 2010 (Figure 36). This trend is seen in both areas of the management unit, though the Bay of Fundy has experienced a steeper rate of decline than the Scotian Shelf (Figure 36).

Similar to commercial CAA, survey catch at age in 4X5Y shows a progressive truncation of the age structure, beginning in the mid-1990s and reaching a low in 2013 and 2014 (Table 17, Figure 37). In these two years, the oldest fish caught on the survey were 5 years old on the Scotian Shelf and 4 years old in the Bay of Fundy (Table 16; Figure 38). Since then, Cod aged 6 through 9 have begun reappearing in the survey catch on the Scotian Shelf, while the Bay of Fundy continues to only see fish aged 1 through 5.

The survey catch at age has tracked periodical large year classes throughout the time series, though the signals appear stronger in the Bay of Fundy catch at age (Figure 38). The frequency of large year classes has decreased substantially in the latter half of the time series, with only one (2001) detected since 1995 (Figure 38). Indices at all other ages show large inter-annual variation and have all decreased in the latter half of the time series (Figure 39, Figure 40). Abundances of age 2 Cod in the recent survey CAA is at historical lows (Table 16).

The stock-recruitment relationship for 4X5Y Cod is not particularly strong (Figure 41), implying that additional factors (e.g., prey abundance, temperature, etc.) may play a role in determining recruitment. The stock-recruitment relationship for 4X5Y Cod should be derived in concurrence with factors identified in the ecosystems consideration analyses (see Ecosystem Considerations).

## ESTIMATES OF RELATIVE AND TOTAL MORTALITY

The relative fishing mortality (catch biomass / RV summer survey biomass) for 4X5Y Cod decreased along with the steep quota reductions implemented throughout the 1990s (Figure 42). Since then, it has remained relatively stable across the management unit, aside from a brief increase in the mid-2000s. Changes in relative fishing mortality within 4X5Y are driven almost entirely by changes within the Scotian Shelf area, as relative fishing mortality in the Bay of Fundy has remained stable until the most recent three years (Figure 42). The latest round of quota reductions in 2015 has resulted in some of the lowest relative fishing mortalities on record (Figure 42).
Estimating total mortality $(Z)$ on groups of ages for 4X5Y Cod is complicated by the persistent truncation in age structure. Given the intermittent presence of age $6+$ fish in the survey catch since 2010 and high inter-annual variability, total mortality was calculated across ages 2, 3 and 4 as a running five-year average for each region (Figure 43). Total mortality on ages 2-4 increased throughout the early 2000s, and has remained at a high level since then; an increase more prominent in the Bay of Fundy than on the Scotian Shelf (Figure 43). Total mortality on older fish (ages $5+$ ) is high across the management unit, as evident by their persistent absence and low abundance in the survey catch.

A high level of total mortality accompanied by unchanging or low relative mortality, as is the case in the Bay of Fundy, indicates that something other than reported landings is causing the disappearance of fish from the western component of 4X5Y. Similarly, recent changes in relative fishing mortality without complementary changes in total mortality, as is the case for the Scotian Shelf, indicates that reported landings are not the only driving force in current population dynamics, including the recent reappearance of older fish. In both cases, factors other than reported landings which could influence the disappearance and reappearance of fish from NAFO areas 4X5Y must be investigated (e.g., changes in catchability, unaccounted for fishing mortality, increases in natural mortality, etc.).

## ECOSYSTEM CONSIDERATIONS

Past assessments of 4X5Y Cod have attempted to account for changes in population trends by examining biology, abundance and distribution of Cod. However, Cod are part of a complex ecosystem and changes to their population structure are inevitably linked to bottom-up or top-down ecosystem processes (e.g., predator abundance, food availability, temperature, etc.). Identifying which of these processes are correlating with dynamics of Cod populations, and deriving associated indicators, are an important step towards implementing an Ecosystem Approach (EA) to fisheries management (Bundy et al. 2017).

For the purposes of this document, a suite of indicators falling into three basic groups were identified: Cod prey, Cod predator and environmental factors. Although many other trophic linkages exist within an ecosystem context, these were the only ones considered at this time. The selected indicators can be correlated with a number of Cod population trends, including abundance of juveniles, spawning stock biomass and condition of Cod in 4X5Y following the method presented by Gomez and Bundy (2017). The relevant ecosystem factors and availability of their respective indices are summarized below.

## COD PREY

Cod are generalist feeders and prey preferences vary by life stage and prey availability (Kohler and Fitzgerald 1969, Daan 1973, Waiwood et al. 1980, Langton and Bowman 1980, Rose and Leggett 1989, McLaren and Avendano 1995, Methven 1999, Link and Garrison 2002, Savenkoff et al. 2006). Larval Cod are known to feed on zooplankton, with several species of copepods (Pseudocalanus and Paracalanus sp) identified as primary prey along the western portion of Scotian Shelf (McLaren and Avendano 1995, McLaren et al. 1997). Johnson et al. (2017) provide abundance indices for copepod nauplii and Pseudocalanus sp along the western Scotian Shelf (Figure 44).
Major prey species for juvenile ( $<37 \mathrm{~cm}$ ) and adult ( $\geq 37 \mathrm{~cm}$ ) Cod in $4 X 5$ Y were identified by summarizing stomach data collected on the RV summer survey between 1999 and 2016 (Table 19). The size division ( 37 cm ) was based on the most recent (post-2000) length at maturity for Scotian Shelf, as it is the lower of the two area-specific values within 4X5Y (Figure 34). Diet of juvenile Cod consisted primarily of krill (Euphausiidae), sand lance (Ammodytidae) and decapods (shrimp and crab). Although some preliminary work has been done to describe relative distributions of krill and sand lance in 4X5Y, no reliable index of abundance exists (DFO 1996, DFO 1996b, Plourde et al. 2016). Similarly, none of the identified shrimp and crab species have a reliable index of abundance for the Bay of Fundy and western Scotian Shelf areas (Table 19).

Prey preferences of adult Cod collected on the RV summer survey comprised of Herring (Clupea harengus), Crabs (Cancer sp.) and Silver Hake (Merlucciidae bilinearis) (Table 19). The 4VWX Herring assessment contains acoustic indices of SSB for several spawning components
within the Bay of Fundy and along the eastern Scotian Shelf (i.e., Scots Bay, German Bank, Trinity Ledge and Little Hope/Port Mouton, Figure 45; DFO 2017b). Juvenile migratory Herring are caught as part of an inshore weir fishery at the mouth of the Bay of Fundy, but no biomass estimate exists and landings are not considered indicative of abundance due to confounding changes in effort (DFO 2015). Silver Hake is assessed across 4VWX using a biomass index from the RV Survey, so an index of abundance can be generated exclusively for 4X. Similar to juvenile prey, no reliable index of abundance exists for the identified crab species (Table 19).

## COD PREDATORS

Cod are preyed upon by a wide variety of marine species, ranging from invertebrates and fish (including larger Cod), to Seals, Whales and seabirds (Palsson 1994, Link et al. 2009, Savenkoff et al. 2006). An examination of stomach content data (1999-2016) from the RV survey found only 38 samples contained identifiable Cod remains, with Atlantic Cod, Halibut, Sea Raven and Monkfish as the main predators. Several attempts to quantify the contribution of Grey seals to natural mortality in Cod on the Scotian Shelf have come up with contradicting conclusions, depending on the method applied (Mohn and Bowen 1996, Fu et al. 2001, Bundy and Fanning 2005, Trzcinski et al. 2006, O’Boyle and Sinclair 2012). For the purposes of this analysis, indicators of predator abundance for juvenile Cod were limited to adult Cod, Halibut and Monkfish (Figure 46; DFO 2017e, DFO 2017h), while those of adult Cod included Halibut, Monkfish and Grey Seals (Figure 47; DFO 2017g, DFO2017e, Hamill et al. 2017). In both cases, the list of predators can be expanded as the work investigating trophic linkages relevant to Atlantic Cod in 4X5Y continues.

## ENVIRONMENTAL INDICATORS

The Atlantic Zone 4 Monitoring Program (AZMP) provides a variety of environmental indicators across the Scotian Shelf and Gulf of Maine (Johnson et al. 2017, DFO 2017f, DFO 2018). The following indicators were chosen for preliminary analysis based on literature review (Planque and Fredou 1999, Clark et al. 2003, Beaugrand and Kirby 2010, Olsen et al. 2011). The authors acknowledge that this list is limited and additional indicators can be added as the work progresses:

- Bottom temperature - Mean anomaly in bottom temperature across NAFO unit 4X, between 100m and 1000m depths (Figure 48; DFO 2018)
- Mean surface temperature - Mean annual anomaly for 4X Scotian Shelf and 4X eastern Gulf of Maine/Bay of Fundy (Figure 49; DFO 2017f)
- Chlorophyll and Bloom parameters: Initiation, Duration (days), Amplitude and Magnitude (Figure 50; DFO 2017f, DFO 2018)

## OTHER CONSIDERATIONS

Notable trends in abundance of other demersal and forage fish along the Scotian Shelf and the Bay of Fundy can be considered as well. For example, despite no apparent recovery in Cod stocks, biomass of Haddock, Halibut, Silver Hake and Redfish along the Scotian Shelf are at record levels (DFO 2015, DFO 2016, DFO 2017e, DFO 2017g).

Cod are part of a complex ecosystem and a wide range of indicators can be considered within the scope of this stock assessment. The current work aims to identify changes in the ecosystem indicators relevant to 4 X 5 Y Cod, working towards implementing an ecosystem approach to management of groundfish fisheries in the Maritime Region. Although this work is still in progress, substantial data gaps have already been identified for some elementary ecosystem
components (i.e., lack of information on Seal and Cod diet, no reliable indicators for Sandlance, Crabs and larval Cod), and these gaps will need to be addressed before an effective ecosystem approach can be implemented.

## CONCLUSIONS

## STOCK STRUCTURE, HISTORY OF FISHERY AND ASSESSMENT

- Although assessed together, Cod in the Bay of Fundy (NAFO areas 4Xqrs5Yb) and Scotian Shelf (NAFO areas 4Xmno) areas of the management unit exhibit distinctly different growth rates, with western fish (Bay of Fundy) growing faster than those from the east (Scotian Shelf). Fish caught in NAFO area 4 Xp consistently exhibit growth characteristics of both regions and the area is considered a mixing zone within 4X5Y.
- Spawning is distributed geographically throughout the 4 X 5 Y area and occurs in the spring and in the fall. Lack of recent, detailed information on spawning events, particularly in the fall, represents a major data gap for interpreting the stock structure of Cod within the 4X5Y management unit.
- In general, a two stock component structure within $4 X 5$ Y seems to persist, with a mixing area in $4 X$ p and some movement taking place between adjacent management areas. Additional work, particularly in the field of genetics, would be highly beneficial in improving understanding of the Cod population structure in this area.
- A concentration of fishing effort in one area of 4 X 5 Y could lead to overexploitation of a single spawning component, while leaving the other unharmed. Management of the fishery should be conducted in a fashion which aims to avoid over-exploitation in any part of the 4 X 5 Y stock area.

## COMMERICIAL FISHERY

- Use of pre-1980 catch data is limited to total amounts, as catch sampling prior to 1980 excluded the Bay of Fundy region, rendering any age or size stratification of the catch within the 4X5Y area inaccurate prior to 1980.
- The issue of misreporting of catches between sub-units of $4 X$ and $5 Y$ throughout the 1980 s necessitates the assessment of 4 X 5 Y as a single unit; assessing Bay of Fundy and Scotian Shelf Cod separately would require additional work to address misreporting throughout the 1980s, or a time series starting post 1990.
- Fishery catch at age (CAA) for Cod in 4 X 5 Y has been undergoing a consistent truncation in age structure since the 1990s, until 2014 when age 6 Cod were barely detectable and ages $8+$ were completely absent. There has been some reappearance of these older fish in the 2016 CAA, but the number of older fish remains very low.
- Commercial weights at age have shown varying trends throughout the time series, but these changes are likely fishery-dependent, as survey weights at age do not exhibit the same trends.

## OBSERVER COVERAGE AND BYCATCH

- Observer coverage of the groundfish fishery has steadily increased since 2013 and is currently estimated at 5-7\%.
- Despite several attempts to bridge knowledge gaps identified by Gavaris et al. (2010), insufficient levels of observer coverage and lack of systematic, unbiased sampling continue to be the major impediments to quantifying the magnitude of Cod bycatch in non-groundfish fisheries.

## RESEARCH VESSEL SURVEY

- Cod in the Bay of Fundy, previously distributed throughout the entire Bay area, have receded away from the coast and are now found primarily in deeper waters at the mouth of the bay, between Grand Manan and Digby Neck. Cod along the Scotian Shelf have all but disappeared from the Shelf edge, and are now concentrated almost exclusively on the banks (e.g., Browns, Lahave, Roseway, Baccaro, etc.).
- Trends in weight at age (WAA) indicate that the two population components continue to exist with relatively little mixing of younger fish between the regions. Lengths at age and condition for 4 X 5 Y Cod from the RV summer survey are stable for both regions.
- Age at $50 \%$ maturity has decreased slightly within the 4 X 5 Y management area, but remains between 2 and 3 years of age, so use of ages 3 and older as spawning stock biomass remains appropriate for this stock.
- The total biomass index for 4X5Y Cod has been steadily declining since the 1990s, but appears to have stabilized at a low level since 2010. This trend is seen in both areas of the management unit, though the Bay of Fundy has experienced a steeper rate of decline than the Scotian Shelf.
- Survey catch at age in 4 X 5 Y shows a progressive truncation of the age structure, reaching an all-time low in 2013 and 2014. Since then, older Cod have begun reappearing in the survey catch on the Scotian Shelf, while the Bay of Fundy continues to only see fish aged 1 through 5.
- Changes in relative fishing mortality within 4X5Y are driven almost entirely by changes within the Scotian Shelf area, as relative fishing mortality in the Bay of Fundy has remained stable until the most recent three years. The latest round of quota reductions in 2015 has resulted in some of the lowest relative fishing mortalities on record.
- Total mortality on ages 2-4 increased throughout the early 2000 s, and has remained at a high level since then; an increase more prominent in the Bay of Fundy than on the Scotian Shelf. Total mortality on older fish (ages $5+$ ) is high across the management unit, as evident by their persistent absence from the survey catch.

## ECOSYSTEM CONSIDERATIONS

- Cod are part of a complex ecosystem and a wide range of indicators can be considered within the scope of this stock assessment. The current work aims to identify changes in the ecosystem indicators relevant to 4X5Y Cod, working towards implementing an ecosystem approach to management of groundfish fisheries in the Maritime Region. Although this work is still in progress, substantial data gaps have already been identified for some elementary ecosystem components (i.e., lack of reliable indicators for Sandlance, Crabs and larval Cod), and these gaps will need to be addressed before an effective ecosystem approach can be implemented.

## ACKNOWLEDGEMENTS

The authors would like to thank industry and port samplers for taking the time to discuss the state of the fishery and providing samples of commercial landings; H. Stone and N. den Heyer for reviewing the document and providing helpful feedback on an earlier draft; M. Finley and M. Cassista Da-Ross for providing Cod stomach content information; J. Sameoto and A. Cook for input on discards from Scallop and Lobster fisheries; N. den Heyer for providing Seal information; R. Singh for providing Herring information; C. Gomez and A. Bundy for help with the Ecosystem information; and Heath Stone for productive discussions on observer coverage.

${ }^{1}$ Switch from Calendar Year to Fishing Year. 1999 Fishing Year landings are from January 1, 1999 to April 1, 2000.
${ }^{2}$ Quota is 1650 mt over two years.
${ }^{3}$ Preliminary number as Fishing Year is not complete. Data pulled December 2017.

Table 2. Number of all groundfish trips, Cod-directed trips and percent Cod-directed of total groundfish trips by gear and year. Groundfish trips were identified based on using a groundfish licence (licence_species 199). A trip is considered Cod-directed if Cod makes up > 50\% of the landings by weight.

Table 8. Landings of other species on Cod-directed trips in $4 X 5 Y$ from commercial logs for fixed gear. Cod-directed trip is defined as having $>50 \%$ catch of Cod by weight. Values in grey cells are in tonnes. Values in white cells are in kilograms. Zeroes are < 0.5 values; dashes are no value.

Table 12. Discard estimates (kg) of Cod from various fisheries in NAFO areas 4X5Y by [a] Sameoto and Glass 2012, [b] Pezzack et al. 2014, [c] Clark et al. 2015, [d] Cook et al. 2017. Estimates are not considered reliable, and should only be used for broad comparisons across fisheries. Zeroes indicate < 0.5 values; dashes indicate no value.

| Red Hake | 0.97\% | Shrimp (general) | 1.29\% |
| Worms (general) | 0.88\% | Sculpin Eggs | 1.08\% |
| Sea Cucumber | 0.82\% | Cod | 0.92\% |
| Starfish (general) | 0.75\% | Snails and Slugs | 0.83\% |
| Herring | 0.59\% | Unidentified | 21.17\% |
| Snails | 0.57\% | - Fish | 20.16\% |
| Unidentified | 7.27\% | - Other | 1.02\% |
| - Fish | 4.11\% |  |  |
| - Other | 3.15\% |  |  |

FIGURES

Figure 1. Unit areas for the 4X5Y Cod management unit (4Xmnopqrs and Canadian portion of 5Yb). Red line depicts how landings are within $4 X p$.

Figure 2. Age-Length relationship from the RV summer survey data (1983-2017) for Scotian Shelf (blue) and Bay of Fundy (red) components of 4X5Y. Dashed lines represent 95\% confidence intervals.

Figure 3. Proxy rates of growth at age (mean length at given age per set) for $4 X 5 Y$ Cod caught on the summer RV survey (1983-2017). Panels are ages, with top left being age 3. Higher ratio_bin values are indicative of faster growth rates.

Figure 4. Age-Length relationships from RV summer survey data for Scotian Shelf (blue), Bay of Fundy (red) and NAFO area 4Xp (purple) over four time periods (panels). Dashed lines represent 95\% confidence intervals.

Figure 5. Aggregated plot of tag release locations (cloud with centroid), recapture locations (coloured points) and area of high mixing rates (hashed cloud).

Figure 6. Age-Length relationships from RV survey data for Scotian Shelf (blue), Bay of Fundy (red) and NAFO area 5Zjm (black) over four time periods (panels). Dashed lines represent 95\% confidence intervals.

Figure 7. Annual (Calendar Year) landings of 4X5Y Cod by gear type. Prior to 1960, 'other' gear consists primarily of catches by handline and longline gears which cannot be separated. Since 1960, 'other' identifies unspecified gear type or gears not falling into one of the identified categories (e.g., seine).

Figure 8. Landings and TAC for NAFO Division 4X5Y Cod by calendar year (January 1st - December 31st). After 1999, landings and TAC are reported by fishing year (April 1st - March 31st).

Figure 9. Total landings by NAFO area since 1980. Upper panel is Bay of Fundy (4Xqrs) and lower panel is Scotian Shelf (4Xmno). Reported landings from $4 X p, 4 X u$ and 5Yb are included on both panels.

Figure 10. Proportion of Cod (Cod weight per trip / all species weight per trip) on groundfish trips since 2002. Red line identifies $50 \%$ of catch weight being Cod.

Figure 11. Bias plot for the 2017 ager test (N=215). Error bars indicate 95\% confidence intervals.

Figure 12. Proportion of landings of 4X5Y Cod by Scotian Shelf (4Xmno), Bay of Fundy (4Xqrs5Yb) and mixing area $4 X$ p. Catches from NAFO area $4 X u$ are excluded from the figure.

Figure 13. Distribution of Cod catches by fixed gear for NAFO Division 4X5Y by month (facets) between 2009 and 2017. Catches are aggregated by 6 minute squares, with darker color indicative of higher catch.

Figure 14. Distribution of commercial Cod catches by fixed gear by calendar year (2012-2017). Catches are aggregated by 6 minute squares, with darker color indicative of higher catch.

Figure 15. Distribution of Cod catches by mobile gear for NAFO Division 4X5Y by month (facets) between 2009 and 2017. Catches are aggregated by 6 minute squares, with darker color indicative of higher catch.

Figure 16. Distribution of commercial Cod catches by mobile gear by calendar year (2012-2017). Catches are aggregated by 6 minute squares, with darker color indicative of higher catch.

Figure 17. Length-frequency distributions of commercial catch by time period, gear and major area.

Figure 18. Commercial fishery Catch at Age (CAA) for $4 X 5 Y$ Cod. Bubble area is proportional to abundance.

Figure 19. Commercial catch at age for Scotian Shelf (upper panel, blue) and Bay of Fundy (lower panel, red) Cod.

Figure 20. Commercial Fishery Weight at Age (kgs) for Scotian Shelf (blue diamonds) and Bay of Fundy (red squares).

Figure 21. Distribution of Cod catches by Fixed (upper panels) and Mobile (lower panels) gears for 2000-2003 (left panels) and 2007-2017 (right panels), aggregated by 6 minute squares. Darker colour is indicative of more catch.

Figure 22. Cumulative annual proportions at lengths of Cod in $4 X 5 Y$ as measured by observers (green) and port samplers (yellow).

Figure 23. Inshore Scallop Fishing Areas (SFA), Scallop Production Areas (SPA) and NAFO divisions in the Maritimes Region, Canada. Sameoto and Glass 2012.

Figure 24. Map of Lobster Fishing Areas (LFA) in the 4X5Y region. Bottom panel is close-up of the fished areas of LFA41 in blue. Red contours indicate RV survey strata. Cook et al. 2017.

Figure 25. 4X5Y Cod catch distribution (kg/tow) for all valid summer RV survey sets between 1985 and 1994.

Figure 26. 4X5Y Cod catch distribution (kg/tow) for all valid summer RV survey sets between 1995 and 2005.

Figure 27. 4X5Y Cod catch distribution (kg/tow) for all valid summer RV survey sets between 2006 and 2016.

Figure 28. Annual numbers at length of Bay of Fundy Cod from the RV Summer Survey. Black line is average number at length from 1983 to 2017.

Figure 29. Annual numbers at length of Scotian Shelf Cod from the RV Summer Survey. Black line is average number at length from 1983 to 2017.

Figure 30. RV Summer Survey weight at age for Bay of Fundy (red squares) and Scotian Shelf (grey diamonds) fish.

Figure 31. Length at age from the RV survey for Scotian Shelf (upper panel) and Bay of Fundy (lower panel) Cod.

Figure 32. Fulton's K (weight/length ${ }^{3}$ ) condition factor for NAFO Division 4X5Y Cod for Scotian Shelf and Bay of Fundy components.

Figure 33. Alternate Condition Factor (Weight at Length Yearly / Weight at Lengthailyears) per 3 cm length bin (facets) for Bay of Fundy and Scotian Shelf.

Figure 34. Length (cm) at 50\% maturity of 4X5Y Cod caught on the RV Spring Survey during the early (pre-1990, upper panels) and late (post-2000, bottom panels) time periods. Panels indicate the Bay of Fundy (BF) or Scotian Shelf (SS) areas.

Figure 35. Age (years) at 50\% maturity of $4 \times 5 Y$ Cod caught on the RV Spring Survey during the early (pre-1990, upper panels) and late (post-2000, bottom panels) time periods. Panels indicate the Bay of Fundy (BF) or Scotian Shelf (SS) areas.

Figure 36. Total biomass index from the Summer RV Survey for all of 4X5Y (black line), as well as Bay of Fundy (dashed red) and Scotian Shelf (dashed grey) stock components, since 1983.

Figure 37. RV Survey indices at age for $4 X 5 Y$ Cod. Bubble area is proportional to survey catch.

Figure 38. RV Survey indices at age for Cod in Scotian Shelf (upper panel; grey) and Bay of Fundy (lower panel, red). Bubble area proportional to survey catch.

Figure 39. Indices at age (number of fish, thousands) for the Bay of Fundy portion of 4X5Y.

Figure 40. Indices at age (number of fish, thousands) for the Scotian Shelf portion of 4X5Y.

Figure 41. Stock-Recruitment relationship (Age 1 abundance vs. SSB) derived from the RV Summer Survey for 4X5Y management unit (top), Bay of Fundy (bottom left) and Scotian Shelf (bottom right) area Cod.

Figure 42. Relative fishing mortality (catch biomass/survey biomass) for Scotian Shelf (grey squares), Bay of Fundy (red triangles) and total 4X5Y area (black circles).

Figure 43. Five-year running average of total mortality on ages 2, 3 and 4 for all of $4 X 5 Y$ (black diamond), Bay of Fundy (dashed red squares) and Scotian Shelf (dashed grey triangles).

Figure 44. Standardized time series of Copepod naupii and Pseudocalanus abundance anomalies along western Scotian Shelf. Johnson et al. 2017.

Figure 45. Standardized time series of relative Herring (DFO 2015) and Silver Hake biomass (DFO 2017).

Figure 46. Standardized indices for Halibut (DFO 2017e), Monkfish (DFO 2017e) and adult Cod biomass (DFO 2017d).

Figure 47. Standardized indices for Halibut (DFO 2017e), Monkfish (DFO 2017) and Grey Seals (Hamill et al. 2017).

Figure 48. Bottom temperature anomaly ( ${ }^{*}$ C) for NAFO sub-area $4 X$. Area is bounded by 100 m and 1000m depths (AZMP - DFO 2018).

Figure 49. Time series of Sea Surface Temperature (1985-2016). A white cell is within 0.5 SD of the long-term mean; red cell is above normal, blue cell is below normal. Minimums and maximums are indicated by a star. Long term means are displayed on the far right hand side. DFO 2017 f .

Figure 50. Standardized time series (1999-2016) of Chlorophyll and Bloom parameter fluctuations (DFO 2017f, DFO 2018).
