## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

#### Abstract

This document presents information on Atlantic Salmon (Salmo salar) from Salmon Fishing Area (SFA) 15 (northern New Brunswick in DFO Gulf Region) of relevance to the development of the status report by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). There are 19 rivers with confirmed presence of Atlantic Salmon in this area of which the Restigouche River is the largest river. Data are presented and interpreted relative to the following: biological characteristics, stocking of fish, area of occupancy based on juvenile surveys, indicators of adult abundance from monitored rivers, freshwater production based on juvenile surveys and smolt production, and factors which may be constraining Atlantic Salmon abundance. For the rivers in this area, the indices of adult abundance suggest that there were more Salmon in the mid to late 1980s than there have been in the past 15 years. As a result of changes in fisheries management, spawning escapement has increased from the 1970s and early 1980s resulting in increased abundance of juvenile Salmon. The principal threats in SFA 15 are: habitat alteration including habitat fragmentation due to non-compliant culverts, hydroelectric power generation, disease, unreported poaching and aboriginal catches and, cumulative effect of ecosystem changes.

## INTRODUCTION

This document presents information on Atlantic Salmon (Salmo salar) from Salmon Fishing Area (SFA) 15 of relevance to the development of the status report by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). SFA 15 is located in northern New Brunswick within the Fisheries and Oceans Canada (DFO) Gulf administrative region. There are 32 potential Atlantic Salmon rivers in this area, of which 15 have freshwater habitat areas quantified (Table 1; Fig. 1). The Restigouche River is the largest river in the area (Table 1; Fig. 1). The Matapedia River, a major tributary in the lower portion of the Restigouche, is assessed separately by the province of Québec. Most of the other rivers are comparatively small with fresh water habitat areas of less than one million $\mathrm{m}^{2}$ (Table 1). A number of smaller rivers in this SFA have no confirmed presence of Atlantic Salmon but they may have small runs of Atlantic Salmon which are not exploited (Table 1).

Habitat area for the Restigouche River (excluding Matapedia) totals 26.39 million $\mathrm{m}^{2}$ (value updated in 2019 from the 21.62 million $\mathrm{m}^{2}$ value to account for the habitat in the main stem of the Restigouche River) with an additional habitat area for the Matapedia River of 6.81 million $\mathrm{m}^{2}$ of wetted area equivalent to 5.12 million $\mathrm{m}^{2}$ of productive habitat units. At an egg deposition rate of 1.52 eggs per $\mathrm{m}^{2}$ (deposition rate for the Restigouche River, DFO 2018), the limit reference point (LRP) in terms of eggs is 47.89 million eggs, equivalent to 8470 large Salmon (at an average of 5656 eggs per large Salmon). This value is $58 \%$ of the conservation requirement previously reported for the Restigouche River (12,042 large Salmon; Randall 1984).
There are 31 other rivers in this area with potential habitat for Salmon. As of 2018, 19 of these rivers had presence of Salmon. For these rivers, the Limit Reference Point deposition rate of 1.52 eggs per $\mathrm{m}^{2}$ is used and applied to estimates of wetted area (DFO 2018; Table 1). Egg requirements to 15 of these 19 rivers are less than 1.5 million eggs or roughly less than 270 large Salmon.

## LIFE HISTORY CHARACTERISTICS

Smolt age varies from 90\% two-year old smolts in the Nepisiguit River (Mowbray and Locke 1998) to 70\% three-year old smolts in the Restigouche River. In the Restigouche River, the proportion of four-year old smolts was historically just under 10\% (1972-1981; Pickard 1983). Since 2002, capture-mark-recapture experiments have allowed collecting scales samples in several tributaries and the main stem of the Restigouche River and are indicating that the large majority of smolts are three-years old (between 90 and 100\% of scales depending on year and location). Two-year and four-year smolts are found in smaller proportion, between about 2-4\% and, 2-6\%, respectively (DFO, unpublished).
Since the mid-2000's, there has been a decrease in the amount of information collected regarding the life-histories of adult Salmon. This is partly due to the shift to catch and release angling in the NB side of the Restigouche River which reduces the opportunity to collect scales as well as the lack of adult monitoring program allowing for the handling of Salmon. Most of the information on sex ratio comes from the Restigouche River: small Salmon ( $<63 \mathrm{~cm}$ fork length) are almost exclusively males ( $93.3 \%$, 6809 small Salmon sexed from 1972 to 2016).
Large Salmon (>= 63 cm fork length) include a small number of one-sea-winter (1SW), two-seawinter (2SW) and three-sea-winter (3SW) maiden spawners, as well as repeat spawners. Four-sea-winter (4SW) maiden Salmon have been interpreted from scales collected on Salmon from the Restigouche River (Peppar and Pickard 1975; Pickard 1983) and both 4SW and one sample of a five-sea-winter (5SW) maiden Salmon were reported from the Nepisiguit River (Mowbray
and Locke 1998). On average and based on sexed samples, the large Salmon group is mostly made of females (62\%, 6731 large Salmon sexed from 1972 to 2011).
Adult Salmon in samples from the Restigouche River range in length from about 40 cm to over 120 cm (Fig. 2). By sea age history, one-sea-winter (1SW) Salmon have an average fork length of 54.5 cm (2.5-97.5 percentiles: 48.3 to 62.5 cm ), 2SW maiden Salmon have an average fork length of 77 cm (2.5-97.5 percentiles: 67 to 88 cm ), and 3SW maiden Salmon have an average of 92.5 cm fork length (2.5-97.5 percentiles:82 to 103 cm ) (Fig. 3). Corresponding predicted mean whole weights of 1 SW, 2 SW and 3 SW maiden Salmon are $1.6,4.6$, and 7.9 kg , respectively (Fig. 4). Repeat spawning Salmon are also commonly found in the rivers of this SFA with 11 years of spawning and sea migrations the oldest life history reported by Pickard (1983). Limited population monitoring does not allow the calculation of the mean generation time but given the importance of three-year-old smolts and the abundance of 1SW and 2SW Salmon in the adult returns, mean generation time (mean freshwater age + mean seas age +1 ) should be between five and six years. The latter is used in the rest of the document.

Egg to fecundity relationship for Restigouche River Salmon has been published by Randall (1989). Large Salmon (sexes combined) have a fecundity of about 5656 eggs per fish and small Salmon (sexes combined) have a fecundity of about 64 eggs per fish (DFO 2018).

Most Salmon return to the Restigouche prior to September 1 with the first bright Salmon in the river by mid to late May. Salmon continue to ascend to the spawning areas into October. Salmon are counted through the Jacquet River and Nepisiguit River counting facilities into late October. Smolts migrate from mid-May to Mid-June (Chaput et al. 2004; Peppar 1982).

Salmon from rivers in SFA 15 undertake long oceanic migrations as shown by recoveries of tagged Salmon from these rivers at West Greenland (see annual International Council for the Exploration of the Seas (ICES) Working Group on North Atlantic Salmon reports).

## OVERVIEW OF DESIGNABLE UNITS (DU)

In the 2010 COSEWIC assessment (COSEWIC 2010), the Salmon populations of the Gaspé peninsula were grouped with Salmon populations of the DFO Gulf Region into one Designatable Unit, the southern Gulf DU. Recent genetic analyses and differences in biological traits (Lehnert et al. in prep ${ }^{1}$ ) suggest that the Gaspé populations are different than the rest of the southern gulf populations. According to this work, the Restigouche River population is classified as a Gaspé population and will be in a different DU than then rest of the SFA 15 rivers.
Stocking of several rivers of SFA 15 with Atlantic Salmon of various life stages has occurred since the government of the day established a fish culture facility on the Restigouche River in 1874 (Table 2). The Restigouche facility was operated by the government of Canada at subsequent locations in Deeside, Flatlands and Charlo in New Brunswick until it was divested to a private "not for profit" organization in 1998. This non-profit organization has continued to operate the Charlo hatchery and conduct similar stocking programs as the previous operator. A subsidiary hatchery facility also was established by the federal government on the Nepisiguit River in 1914 and operated for some years.
An examination of early reports indicates that most stocking occurred at the early life stages of fry, advanced fry and fingerlings. The reports also indicate that eyed Atlantic Salmon eggs were

[^0]routinely transferred from one government hatchery facility to another. For example, it was common for eggs of Chaleur Bay and Restigouche origin to be transferred to hatcheries located at Grand Falls and Florenceville on the Saint John River system for grow out and stocking. Similarly, the reports indicate that eyed eggs of Miramichi origin were transferred to the Restigouche hatchery for grow out and stocking. These records also indicate that the majority of broodfish were of early run, captured near the New Brunswick shore of the Chaleur Bay and purchased from the commercial fishermen of the district and held and spawned at the government owned New Mills holding pond which had been constructed prior to 1919 (Department of Fisheries, Annual Report on Fish Culture 1937). Broodfish were also captured from the Restigouche River and held in the river in floating cages called pontoons prior to spawning from the early 1940's until the government holding pond was constructed in the early 1960's at Hailes Brook adjacent to the Restigouche River. In recent years, 1980 to present, Salmon from various tributary/river stocks were captured by various methods and the subsequent progeny utilized in area specific Salmon enhancement programs.

Hatchery stocking was especially important in the Nepisiguit River while modest stocking programs occurred in the Restigouche River. An active stocking program has been carried out in the Nepisiguit River for the past four decades, initially to restore the population following a spill of mining waste and overfishing, and subsequently for enhancement purposes (Locke 1998). Stocking still occurs in the Nepisiguit and Restigouche rivers. Returns to the Restigouche River from stocking programs are considered to be less than $1 \%$ of total returns. Hatchery-origin Salmon have represented important proportions of the returns to the Nepisiguit River, as high as $75 \%$ of both small and large Salmon (Locke et al. 1994) but the hatchery contribution to this river is much reduced in recent years (Chaput et al. 2006). In recent years, stocked fish have stopped being marked making it challenging to evaluate the contribution of this program to the entire population.

## TRENDS IN POPULATION INDICATORS

## DESCRIPTION OF THE INDICATORS

Information on adult Salmon abundance comes primarily from angling catches and effort (Table 3). Abundance of adult Salmon in the Restigouche River is inferred from angling catches, counts at headwater barriers, and when possible from end of year spawner counts by snorkeling (Tables 4, 5, 6; Chaput et al. 2000). Counts of Salmon to a headwater tributary are available for two tributaries of the Restigouche River (Table 4; details in Chaput et al. 2000). A counting barrier on the Jacquet River near the head of tide provides incomplete counts of adults in most years (Table 4). A counting fence has been operated on the Nepisiguit River over the past four decades but installation dates, operational details and washouts have compromised the completeness of the data (Locke et al. 1994; Locke et al. 1997a, b). Juvenile surveys have been conducted annually in the Restigouche River since 1972 (Tables 7 - 9) and abundance indices of juveniles are available for some years from the Jacquet River and the Nepisiguit River. While sampling techniques across rivers are similar, protocols and estimation methods of juvenile abundance are not necessarily standardized across organizations leading to challenges in comparing abundance levels between and sometimes within rivers.

In the Restigouche River, smolt monitoring programs began in 2002 to assess the production and biological characteristics of smolts from the Restigouche River and some of its tributaries (Chaput et al. 2004).

Abundance and trends are evaluated relative to the recent 19 years, 2001 to 2019. This time period has been chosen because it roughly represents three generations, the time period
required by COSEWIC (2015) to assess population trends. Abundances are also put in context of the longer time period when available. Trend in an abundance index ( $\operatorname{Ln}(\operatorname{lndex})$ ) is characterized as the instantaneous rate of change (Z) over the period 2001 to 2019 With the percent change calculated as $100^{*}\left(\exp ^{2^{* 1}}-1\right)$.

## TRENDS OF THE INDICATORS

## Adult returns

The Northwest Upsalquitch fence operated as a counting fence until 2012. The only count available for the Restigouche river in recent years comes from the Causapcal River (tributary of the Matapedia). Over the last 19 years there has been a significant decline in the amount of small Salmon counted at these two fences. At the Upsalquitch fence, while there was no significant decrease of large Salmon in the last 19 years, counts were much higher during the mid-80s to mid-90's time period (Table 3; Fig. 5).
Capture and Catch per unit effort (CPUE) indices from the recreational fishery for large Salmon decreased by about 30\% in the Matapedia River (QC). Note that since 2000, release of Salmon has been encouraged in Quebec. However, the percentage of small and large Salmon released is only available from 2016 to 2019 and, the average proportions are used for the rest of the time-series. Additionally, since 2016 and a new Atlantic Salmon management plan in Quebec (Ministère des Forêts, de la Faune et des Parcs 2016), the retention of large Salmon has been reduced which could partly explain the decline in catches.
On average, about 7,000 Salmon (small and large) are angled annually in the Restigouche River (Table 3; Fig. 6, included released fish). In the last five years, about 5,500 Salmon were angled annually but this number could be an underestimate since some private camps have stopped reporting their captures.
Over the last three decades, assessment data have also been collected from the Jacquet River and the Nepisiguit River. Counts of Salmon at a protection barrier near the head of tide on the Jacquet River have frequently been incomplete due to washouts or late installations (Table 4). Adult abundance in the Jacquet River had exceeded the conservation requirement defined at that time at the start of the time series but in recent years, its status relative to reference points is unknown due to incomplete data (Fig. 5).
The status of the Nepisiguit River has been uncertain. Estimates of returns and escapements based on fence counts, which are generally incomplete, indicated that conservation requirements had been achieved in only 2 of 15 years when the stock was assessed (1982 to 1996) [Locke et al. 1997a, b]. In recent years, number of fish captured at the fence has been variable and suggest that conservation requirements are not achieved (Table 1).
There are no measures of marine return rates for any rivers in this area.

## Freshwater production

Juvenile abundance in the Restigouche River has been monitored annually since 1972. A recent effort to standardize density estimation allows the estimation of comparable densities throughout the whole Restigouche watershed (Dauphin et al. 2019, 2021). Densities of fry, small parr and large parr all increased post-1984 and seem to have declined during the 2000's and have been at the same level in the last 13 years (Figs. 7-9; Tables 7-9). Notable exception is the significant increase of large parr densities in most of the tributaries sampled. However, this needs to be put in the context of very low densities (i.e. less than 5 individuals per $100 \mathrm{~m}^{2}$ to about 5 individuals per $100 \mathrm{~m}^{2}$ ).

Smolt production has been assessed since 2002 in several tributaries of the Restigouche and for the whole watershed through capture-mark-recapture experiments (Dauphin, in prep. ${ }^{2}$ ). The current assessment ignores the fact that some years, the earlier part of the smolt run could not be sampled. Smolt production in the Kedgwick River varies between 50 and 250 thousand smolts with low abundances in the last four years (Fig. 10; Table 10). The Restigouche smolt production has declined by about $60 \%$ in the last 19 years with a production of about 400 thousand smolts in the last four years (Fig. 10; Table 11).
Salmon fry densities in the Nepisiguit River increased between the 1980s and the 2000s and seem to be varying with no significant trends in the recent years whereas parr abundance has declined (Fig. 11). However, similarly to the Restigouche River, this has to be put in the context of low densities. Juvenile abundances in the Jacquet River are only available until 2014 and during the last 13 years of available data the densities of fry and parr were on a declining trend (Fig. 12).

For all rivers, electrofishing sampling sites are usually chosen based on habitat suitability for juvenile Atlantic Salmon rearing and ease of access for sampling crews. This site selection process can be a source of bias when upscaling densities at the site-scale to the watershedscale.

## TRENDS IN DISTRIBUTION AND DECLINE OR FLUCTUATIONS (COSEWIC CRITERION B)

There are 32 rivers in this area with potential habitat for Salmon. As of 2018, 19 of these rivers had presence of Salmon confirmed. For these rivers, the Limit Reference Point (LRP) deposition rate of 1.52 eggs per $\mathrm{m}^{2}$ is used and applied to estimates of wetted area (DFO 2018; Table 1). The largest river in this area is the Restigouche River with a total fluvial area of 31.51 million $\mathrm{m}^{2}$ ( 26.39 million $\mathrm{m}^{2}$ when excluding the Matapedia River, QC). Egg requirements to 15 of these 20 rivers are less than 1.5 million eggs or roughly less than 270 large Salmon. Additionally, Little River, which was considered polluted by effluent from a now closed mine seems to have improved biological characteristics (Minnow 2017) and has been stocked with juvenile Atlantic Salmon in the last few years (there are currently no egg requirement for this river). As of 2020, the sampling exercise conducted in 2008 to assess the presence of juvenile Atlantic Salmon across SFA 15 rivers has not been repeated and therefore there are no recent updates regarding the presence/absence of juveniles for the rivers who do not benefit of yearly monitoring program (e.g. Restigouche and Nepisiguit Rivers). As an illustration of typical sampling occurring in SFA 15, the presence/absence of juveniles in rivers sampled in 2019 is summarized in Figure 13.

Juvenile Salmon are distributed throughout SFA 15 and were found at various abundance levels in all rivers sampled in 2019. In many rivers surveyed, two or three cohorts (fry, small parr, large parr) were captured indicating that there had been multiple years of spawning success (Fig. 13).
Long term juvenile abundance surveys completed on Restigouche (New Brunswick) provide an indication of the temporal changes in juvenile Salmon presence and abundance, from 1972 to 2019. In the Restigouche River, there has been varying levels of site occupancy by Salmon fry with no trend in the proportion of sites sampled which had densities > 1.0 fish per $100 \mathrm{~m}^{2}$. (Fig. 14). There was a significant increasing trend in the proportion of sites which had large parr (age-2+ years) at densities greater than 1 fish per $100 \mathrm{~m}^{2}$ (Fig. 14).

[^1]
## ESTIMATE OF TOTAL POPULATION SIZE

## RESTIGOUCHE RIVER

In the Restigouche River, based on the requirement of about 7,000 large Salmon (DFO 2018) and an assumed catch rate of $40 \%$ in the angling fishery (Randall et al. 1990), the Limit Reference Point would have been met in 4 of 13 years since 2007 (Table 1). Additionally, since 1999, snorkel counts are conducted in the Restigouche River (excluding the Matapedia River). During the last 13 years (2007-2019), snorkel counts were complete in 11 years and, based on these counts, the LRP was met once during these years. Spawning escapements under the LRP are consistent with lower fry densities in some tributaries (Fig. 7; Table 7) of the Restigouche as well as a decrease in the smolt production (Fig. 10; Tables 10-11).
There are uncertainties associated with both methodologies used to derive spawning escapement: the angling catch rate is likely to change over years and in recent years, some private camps have stopped reporting their catches; snorkel counts are subject to environmental conditions and are likely a proxy for the minimum number of spawners present in the rivers.

## SFA 15

Estimates of total abundance (returns and spawners) of adult Salmon in SFA 15 are derived from indicators in the Restigouche River, the major river in this area. The returns and spawners are estimated for the Restigouche River, exclusive of returns to the Matapedia River which are included in Quebec zone Q1.
The Restigouche River stock assessment is based on angling catch with assumed exploitation rate between $30 \%$ (min.) and $50 \%$ (max) with estuary catches added to the estimates of returns. Catch and release for large and small Salmon was implemented in SFA 15 in 1984 and 2015, respectively. Catch and release mortality is assumed to be 6\%. Since the mid-1990s the First Nation catches are not reported and an average value is used, an important source of uncertainty.
Return and spawner estimates for SFA 15 are based on Restigouche River data, scaled up for SFA 15 based on the average ratio of total SFA 15 to Restigouche River angling catches (1.235 and 1.145 for small and large Salmon, respectively). The minimum and maximum return and spawner estimates are derived from the minimum and maximum angling catch rate ( $\mathrm{min}=30 \%$; $\max =50 \%$ ) (Fig. 15). Additionally, the Restigouche River snorkel counts are scaled up for SFA 15 based on the ratio of total SFA 15 to Restigouche fluvial area.
The estimated abundance of small Salmon and large Salmon combined (returns) has been variable throughout the time-series, oscillating around 15 thousand fish with a maximum of 30 thousand fish during in 1988 and 2011. In the recent five years, the average abundance has declined to 12 thousand fish (Fig. 15). Estimated total abundance in SFA 15 of small Salmon has decreased by $42 \%$ and for large Salmon by $21 \%$ over the past 19 years (Fig. 15). There is a large variability in estimates of small and large Salmon returns which are driven by the range of angling catch rate used to produce the minimum and maximum estimates.

## THREATS

In the context of the identification and management for species at risk, a threat, is 'an activity or process (both natural and anthropogenic) that has caused, is causing, or may cause harm, death, or behavioral changes to a species at risk or the destruction, degradation, and/or impairment of its habitat to the extent that population-level effects occur' (Environment Canada 2006). In essence, it is an activity that imposes a stress on a species at risk population
which contributes to or perpetuates its decline, or limits its recovery. In the case of Atlantic Salmon, the elevated marine mortality and declining returns in recent years are stress caused by unknown (but hypothesized) threats.
A semi-quantitative assessment of the impact of habitat-related threats to Salmon is summarized in Table 12. The principal threats are: habitat alteration including habitat fragmentation due to non-compliant culverts and mining and forestry activities (DFO and MNRF 2009). Following the classification described in Master et al. (2012) these threats impact are classified as "High". Ecosystem changes, fish diseases, aboriginal fisheries (i.e. the lack of reporting) and illegal fishing are classified as "Medium". This would put the SFA under a very high overall threat impact.
Cairns (2001) presents and describes 62 hypotheses which may explain the decline in abundance of Atlantic Salmon. Any or all of the factors described may be acting to constrain present abundance of Atlantic Salmon in the Gulf rivers. A few of these factors are discussed below.

## FISHERIES

Losses of large Salmon from fisheries are restricted to First Nations fisheries and from incidental mortalities associated with catch and release fisheries. The reports of First Nations catches of Salmon in SFA 15 available to DFO are limited and/or incomplete. Based on fisheries and abundance values used in assessments since 2000, about 20\% of large Salmon (range 7-30\%) are lost to First Nations Fisheries.

In the recreational fishery, mandatory catch and release of large Salmon has been in effect since 1984 in the rivers of SFA 15 (Restigouche NB exclusive of Matapedia and portions of Patapedia). A catch and release mortality rate of $6 \%$ has been defined from studies on the Restigouche River (Courtenay et al. 1991) and is used for all recreational fisheries in SFA 15.

At an assumed exploitation rate of $40 \%$ ( $30 \%$ to $50 \%$ range), the losses of large Salmon from catch and release is assumed to be $2.4 \%(1.8 \%$ to $3.0 \%)$ of the returns to freshwater. Under these hypotheses the exploitation on egg bearing females is thus expected to be low to moderate (Table 12). However, in the context of global climate change and increasing temperatures, catch and release mortality could be and/or become higher (e.g. Van Leeuwen et al. 2020).

## MIXED STOCK MARINE FISHERIES

## Saint Pierre and Miquelon fishery

A marine fishery for Atlantic Salmon using gillnets takes place along the coast of the islands of Saint Pierre and Miquelon (SPM; France), off the south coast of Newfoundland. There are no anadromous Salmon producing rivers in the islands of SPM. Annual reported harvests have generally been less than 3 tonnes ( t ) with a peak reported harvest of 5.3 t in 2013; the reported harvest in 2019 was 1.3 t (Fig. 16). The estimated number of fish harvested annually varies dependent on the quantity of small Salmon and large Salmon in the catches. There is insufficient information from the sampling program to reliably estimate Salmon catch numbers but based on available information, the harvest of Salmon in number of fish has ranged from a low of just under 300 fish to a high of 1,800 fish size groups combined (Fig. 16)

Based on genetic analyses, the Salmon sampled from the fisheries catches in SPM come predominantly from three regional groups: southern Gulf group (part of SFA 15, all of SFAs 16 to 19), Quebec (including the Gaspé regional group that includes the Restigouche

River of SFA 15) and the Newfoundland regional group (Bradbury et al. 2016a). The proportions of the annual samples which were assigned to the Quebec reporting group ranged from 0.20 to over 0.50, for the period 2004 to 2017 (Fig. 16). The proportions of the fishery samples assigned to the Gulf reporting group (based on a single nucleotide polymorphism (SNP) panel of markers) was 0.30 in 2019 (ICES 2020).

## Labrador subsistence fisheries

Historically, Atlantic Salmon originating from rivers of SFA 15 were recovered in the commercial fisheries of Newfoundland and Labrador. The commercial fishery in Newfoundland closed in 1992 and the commercial fishery in Labrador closed in 1998. Since 1998, there are four Indigenous communities with food social and ceremonial fisheries for Atlantic Salmon and there is a licensed subsistence food fishery for residents of Labrador in which a bycatch allocation of Salmon is provided. These fisheries take place in the estuaries and coastal areas of Labrador using gillnets.

The fishery is sampled for biological characteristics and tissue samples are collected for determination of the origin of Salmon in the catches. Over the period of analyses, 2006 to 2019, the estimated origin of the samples of the catches was dominated (> $95 \%$ ) by the Labrador reporting groups. No samples have been assigned to the Gulf reporting group (Bradbury et al. 2015, 2018; ICES 2020).

## West Greenland

The Atlantic Salmon fishery at West Greenland takes place on mixed stocks of Atlantic Salmon originating from rivers of eastern North America and Europe, with varying annual proportions of the catches from the two continents (Bradbury et al. 2016b; ICES 2020). Atlantic Salmon originating from rivers of SFA 15 undertake high seas feeding migrations to the Labrador Sea and are intercepted in the mixed stock fisheries at West Greenland, mostly during their second summer at sea and as repeat spawners. The fishery at West Greenland had peak reported catches of 2679 t in 1971 but the fishery catches have declined to generally less than 50 t since 1998. The number of Salmon originating from rivers of eastern North America harvested annually at West Greenland has ranged from 5,100 to 13,500 fish during the recent 10 years (ICES 2020). The majority (> 95\%) of the Salmon harvested at West Greenland are characterized as 1SW non maturing Salmon, fish which would mostly have returned to rivers as 2SW Salmon if they had survived their second year at sea.
The exploitation rate at West Greenland on Salmon of North American origin, estimated as the ratio of the catch of 1SW non-maturing Salmon of North American origin divided by the estimated pre-fishery abundance of North American origin 1SW non maturing Salmon in the North Atlantic just prior (Aug. 1) to the fishery, declined from peak exploitation rates of just over $40 \%$ in the early 1970s to oscillating values around $10 \%$ since the early 2000s (ICES 2020). The exploitation rate on North American origin Salmon for the most recent year, 2018 catches, was estimated at $13.2 \%$ (ICES 2020).
Genetic stock identification using microsatellite markers initially and SNP panels in recent years have consistently shown that the sampled catches at West Greenland originate primarily from three regions of eastern Canada including Labrador, southern Gulf reporting group, and Quebec reporting groups (Bradbury et al. 2015; ICES 2018, 2020). The Gaspé reporting group represented $26 \%$ of the samples of North American origin Salmon in 2019 (ICES 2020).

## HABITAT ALTERATIONS

Forestry, agriculture, and rural development all impact in various ways the fresh water habitat of Atlantic Salmon in this SFA.

One pulp mill is present on the Restigouche River (Atholville), its operation requires water intake and the release of a treated effluent in the Restigouche River.

There are several zinc-lead-silver-copper-gold mines located in the Bathurst mining camp area (about 50 km west of Bathurst). Due to the nature of these activities there are potential risks of chemically contaminated water spills. The Little River (Bathurst area) which has been exposed to a toxic mine effluent for years seem to show an improvement in its biological characteristics since the mine's closure in 2013 (Minnow 2017). In the last two years, instream incubators have been used to stock the Little River with juvenile Atlantic Salmon and small numbers of fry and parr have been found during the electrofishing sampling.

Several rivers in this area have natural impassable falls at varying distances from the ocean, limiting access to Salmon: South Charlo River, Millstream, Tetagouche River, Nepisiguit River.

There are a few rivers and tributaries with water control structures which impede the migration of Atlantic Salmon. These are located at the mouth of the Charlo River and the Eel River approximately five kilometers upstream from the mouth. The Eel River dam was dismantled in 2010. Dewatering of juvenile rearing areas during low flow conditions happens frequently in a short portion of the Charlo River.

## TRANSPORT AND NOISE

There are several harbors in the area (e.g. Dalhousie, Belledune). Additionally, at times there are important boating activities on the river with unknown impact on Salmon population and habitat.

## ECOSYSTEM CHANGE

Within the context of global climate changes, the occurrence of warm water temperatures and low water level events seems more frequent. These events likely have effects on a cold-water species such as Atlantic Salmon. In recent years, warm water protocols have been developed in the Nepisiguit and Restigouche River to reduce or stop angling when water temperatures reach a certain threshold.

## DISEASE

There is a history of outbreaks of the fish disease furunculosis, caused by the bacterium Aeromonas salmonicida in the Restigouche River and the disease is considered ubiquitous in this river. Mortalities on Salmon in the Restigouche River were most important in the 1970s when hundreds of fish were reported dead during warm and low water events. Since then, annual reported mortalities have declined despite the confirmed presence of furunculosis in some diagnosed fish. The fungal pathogen saprolegnia has been occasionally associated with adult mortalities ranging from a dozen to several hundred individuals on a given year.

## TABLES

Table 1. River characteristics for Salmon Fishing Area 15. Source of evidence of Salmon presence include adult sampling (Adult), from juvenile monitoring (Juvenile) or from angling catches (Angling). Presence/absence for juveniles was surveyed in 2008. Fluvial area estimate references are: 1 - DFO Science Gulf Region (Unpubl. data); 2 - Anonymous (1978); 3 - Drainage area from Data Warehouse Report Sept. 2014; fluvial area based on proportion equal to 0.0015 of watershed area (average of seven index rivers from Anonymous 1978). Biological data is not available for each river therefore reference rivers are used: River 1 - Restigouche; Rivers 2-29: Nepisiguit; Rivers 30-32: Tabusintac. X: presence confirmed in 2019, (X): presence confirmed during the 2008 electrofishing sampling campaign but not repeated since.

Table 4. Annual counts of small Salmon and large Salmon at fences and protection barriers within SFA 15. $\dagger$ : indicates that there were one or several washout events leading to potentially incomplete counts. Note that after 2013, the counting fence in the Northwest Upsalquitch was converted to a holding fence and therefore no counts are available.

Table 5. Harvest and angling data and, returns and spawners estimates of small Salmon for Restigouche River and total SFA 15. Two spawners estimates are provided: one assuming a 40\% exploitation rate in the Restigouche River and another one based on snorkel counts conducted in the fall in the Restigouche river and prorated to the total fluvial area available in SFA 15. $t$ : due to environmental conditions, the snorkel counts are sometimes incomplete and will likely result in an underestimation of the total abundance. Since the mid-90's, there has been a lack of reporting from First Nations fisheries. As a consequence, historical average catches have been used in the assessments. Average values are in italic.

Table 6. Harvest and angling data and, returns and spawners estimates of large Salmon for Restigouche River and total SFA 15. Two spawners estimates are provided: one assuming a 40\% exploitation rate in the Restigouche River and another one based on snorkel counts conducted in the fall in the Restigouche river and prorated to the total fluvial area available in SFA 15. †: due to environmental conditions, the snorkel counts are sometimes incomplete and will likely result in an underestimation of the total abundance. Since the mid-90's, there has been a lack of reporting from First Nations fisheries. As a consequence, historical average catches have been used in the assessments. Average values are in italic.

Table 10. Smolt population estimate in the Kedgwick River based on annual capture-mark-recapture experiments. Weight at 13 cm (g) is predicted based on an annual length weight relationship fitted for each tributary. $t$ : some years, due to environmental or logistic constraints it was not possible to install the smolt trap in time to catch the beginning of the smolt migration, the current abundance model does not take this in account and population abundance for these years are likely underestimated.

| Year | Population estimate |  |  | Fork length (mm) | Weight at $13 \mathrm{~cm}(\mathrm{~g})$ | Prop. female | Prop. Smolt age |  |  |

Table 12. Summary of threats to, and rating of effects on recovery and/ or persistence of Atlantic Salmon in SFA 15, Northern NB (DFO and MNRF 2009; Master et al. 2012). Colors indicate the level of the threat factor as computed by Master et al. (2012): dark green = low ; light green $=$ Medium; yellow $=$ High and red $=$ Very High.

| Potential sources of mortality /harm Permitted and unpermitted activities | Source (with examples) | Scope (next 10 years) | Severity (next 10 years) | Timing | Comments - Management Alternatives/ Mitigation |
| :---: | :---: | :---: | :---: | :---: | :---: |
| PERMITTED ACTIVITIES |  |  |  |  |  |
| Directed Salmon Fishing | Aboriginal | Large | Moderate | High | Control harvest through agreements between DFO and First Nations, however no reporting of harvest since the 2000. |
|  | Recreational: retention \& release | Large | Slight | High | In NB, catch and release only which is believed to have low mortality. However this might change in the context of increasing water temperatures. |
|  | Commercial (domestic) | Negligible | Neutral | Negligible | All commercial fisheries closed. |
|  | High Seas (West Greenland / St. <br> Pierre - Miquelon) | Small | Slight | High | Reductions in internal use fisheries in those areas. |
|  | Illegal (poaching) | Large | Moderate | High | Continue use of compliance monitors on selected watersheds, including Aboriginal guardians. |
| Bycatch of Salmon in Fisheries for Other Species | Aboriginal | Negligible | Neutral | Negligible | All bycatch mandatory release. |
|  | Recreational | Negligible | Neutral | Negligible | All bycatch mandatory release. |
|  | Commercial near-shore | Negligible | Neutral | Negligible | All bycatch mandatory release. |
|  | Commercial distant | Negligible | Neutral | Negligible | None apparent. |
| Salmon Fisheries Impacts on Salmon Habitat | Aboriginal | Negligible | Neutral | Negligible | None apparent. |
|  | Recreational | Negligible | Neutral | Negligible | None apparent. |
|  | Commercial | Negligible | Neutral | Negligible | None apparent. |

| Potential sources of mortality /harm Permitted and unpermitted activities | Source (with examples) | Scope (next 10 years) | Severity (next 10 years) | Timing | Comments - Management Alternatives/ Mitigation |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Illegal | Negligible | Neutral | Negligible | None apparent. |
| Mortality Associated with Water Use | Power generation at dams \& tidal facilities (turbine mortality, entrainment, stranding) | Large | Slight | High | Thermal generation stations in Dalhousie and Belledune, NB, must comply with conditions of operating license and sec. 22 of the Fisheries Act. |
| Habitat Alterations | Municipal waste water treatment facilities | Large | Slight | High | Few communities; Ensure current projects and future developments meet standards. |
|  | Pulp \& paper mills | Large | Slight | High | Pulp and paper mills comply with pulp and paper effluent regulations. |
|  | Hydroelectric power generation (dams \& reservoirs, tidal power): altered behavior \& ecosystems | Large | Moderate | High | Must comply with section 22 and 35 of the Fisheries Act. |
|  | Water extractions | Large | Slight | High | Must meet regulations in place; monitoring; develop regional guidelines. |
|  | Urbanization (altered hydrology) | Large | Slight | High | Mostly small communities ; Project redesign/ existing regulation - monitoring. |
|  | Infrastructure (roads/culverts) (fish passage) | Pervasive | Serious | High | Many culverts present all over the watersheds, many are non-compliant and can fragment the habitat. More monitoring/ enforcement of existing regulations; GMRC/DFO ongoing studies. |
|  | Aquaculture siting | Negligible | Unknown | High | None apparent. |
|  | Agriculture / Forestry / Mining, etc. | Large | Serious | High | Potential mineral processing; past mining/ processing; Enforcement/ monitoring of existing suite of regulations; compensations where required. |
|  | Municipal, provincial \& federal dredging | Small | Slight | High | Follow regulations in place; mitigations and compensations as required; minimize amount. |

| Potential sources of mortality /harm Permitted and unpermitted activities | Source (with examples) | Scope (next 10 years) | Severity (next 10 years) | Timing | Comments - Management Alternatives/ Mitigation |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Shipping, Transport and Noise | Municipal, provincial, federal \& private transport activities (including land and water based contaminants/ spills) | Unknown | Unknown | High | None apparent. |
| Fisheries on Prey of Salmon (e.g. capelin, smelt, shrimp) | Commercial, Recreational, Aboriginal fisheries for species $a, b$, c etc. | Unknown | Unknown | High | None apparent. |
| Aquaculture (Salmon and other species) | Escapes from fresh water, marine facilities, disease, parasites, competition, effects on behaviour and migration, genetic introgression | Small | Slight | High | Fish health regulations, Introduction and transfer regulation. |
| Fish culture / stocking (noncommercial, including private, NGO, government) | Impacts on effective population size, over representation of families, domestication | Small | Slight | High | Must comply with Introduction and Transfers guidelines. |
| Scientific Research | Government, university, community and Aboriginal groups | Negligible | Slight | High | Minimal removals for scientific purposes. None apparent. |
| Military Activities | Field operations, shooting ranges | na | na | na | None apparent. |
| Air Pollutants | Acid rain | Negligible | Unknown | High | None apparent. |
| UN-PERMITTED ACTIVITIES |  |  |  |  |  |
| Introductions of non-native / invasive species | Smallmouth bass, chain pickerel, muskellunge, rainbow trout, invertebrates, plants, algae | Unknown | Slight | High | Increase monitoring and enforcement activities -Conduct education programs. |
| International High Seas Targeted | Flags of convenience | na | na | na | None apparent. |

| Potential sources <br> of mortality /harm <br> Permitted and un- <br> permitted <br> activities | Source (with examples) | Scope <br> (next 10 <br> years) | Severity <br> (next 10 <br> years) | Timing | Comments - Management Alternatives/ Mitigation |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Ecotourism and <br> Recreation | Private companies \& public at large <br> (water crafts, swimming, etc.) effects <br> on Salmon behaviour \& survival | Large | Slight | High | Conduct education programs - Increase enforcement <br> activities. |
| Ecosystem change | Climate change, changes in relative <br> predator / prey abundances, disease | Large | Moderate | High | Rivers in the area are more and more affected by low <br> water levels and warm water temperatures. |
| Fish diseases | Furunculosis, Saprolegnia | Large | Unknown | High | None apparent. |

## FIGURES

Figure 1. Rivers within Salmon Fishing Area (SFA) 15 of northern Gulf New Brunswick. Index numbers refer to rivers in Table 1. Index numbers 1a to 1d refer to position of major tributaries of the Restigouche River (Index 1): $1 a=$ Matapedia, $1 b=$ Upsalquitch, $1 c=$ Patapedia, $1 d=$ confluence of Kedgwick and Little Main Restigouche.

Figure 2. Size distribution (fork length; cm) for male (M), and female (F) Salmon from the Restigouche River. Data are from 1972 to 2019 and come from various fence, trapnet and angling samples. Since 2015 (catch and release implementation in NB) there has been no adult Salmon biological data collected for NB.

Figure 3. Fork length (cm) at age defined by sea age and spawning history for Atlantic Salmon from the Restigouche River. Each tick mark corresponds to a life-history and are organized by maiden age and total number of spawning event (i.e. maiden fish are the furthest left in each categories). Dots indicate the median fork length, boxes and vertical bars indicate the 25th-75th and 2.5th-97.5th interquantile range, respectively. Numbers above each boxplot indicate the number of fish sampled for each life-history during the period 1972-2019.

Figure 4. Weight to length relationship for Atlantic Salmon from the Restigouche River. Due to the large number of samples, data are binned and color coded in function of the number of samples. Data are from the period 1972 to 2019.

Figure 5. Counts of all small (left panels) and large (right panels) adult Salmon at the Northwest Upsalquitch Barrier (upper), Causapscal Barrier (middle) and Jacquet barrier (lower). When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 6. Recreational catch (upper panels) and catch per rod day (lower panels) in the Restigouche (left panels) and the Matapedia (right panels) rivers, 1982 to 2019. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 7. Average fry densities in the Restigouche River and tributaries. Dots indicate the median and light and dark ribbons indicate the 2.5 th-97.5th and 25th-75th interquantile range, respectively. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 8. Average small parr densities in the Restigouche River and tributaries. Dots indicate the median and light and dark ribbons indicate the 2.5th-97.5th and 25th-75th interquantile range, respectively. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 9. Average large parr densities in the Restigouche River and tributaries. Dots indicate the median and light and dark ribbons indicate the 2.5th-97.5th and 25th-75th interquantile range, respectively. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

## Kedgwick

Restigouche

Figure 10. Smolt abundance in the Kedgwick River (upper panel) and in the whole Restigouche (Matapedia included). Dots indicate the median and the grey ribbon indicates the 2.5th-97.5th interquantile range. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

## Fry

Figure 11. Average fry (upper panel) and parr (lower panel) densities in the Nepisiguit River. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

## Fry

Parr

Figure 12. Average fry (upper panel) and parr (lower panel) densities in the Jacquet River. When the slope of the exponential linear regression is significantly different than zero ( $p<0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 13. Presence/absence of juvenile Atlantic Salmon, by number of cohorts (fry, small parr, large parr) at electrofishing sites in rivers of SFA 15 sampled in 2019. Note: no distinction is made between small and large parr during data collection in rivers South of the Jacquet River, therefore the maximum number of cohort than can be observed in these rivers is two.

Figure 14. Number of sites sampled annually in the Restigouche River, including Patapedia and Matapedia River (upper panel) and proportion of those sites containing more than 1.0 juvenile per $100 \mathrm{~m}^{2}$ by age/size group (lower panel).

Figure 15. Estimated abundance of small (left panels) and large (right panels) Salmon prior to (returns, upper panels) and post (Spawners, lower panels) fisheries in SFA 15 from 1970 to 2019. Plain black dots indicate estimates obtain based on an angling catch rate of $40 \%$ in the Restigouche River. The vertical segments represent estimates obtained with an angling catch rate range of 30 to $50 \%$. The blue squares indicate spawner estimates based on complete (plain squares) or incomplete (empty squares) snorkel counts conducted during the fall in the Restigouche. When the slope of the exponential linear regression is significantly different than zero ( $p 0.05$ ) or not the curve is displayed in plain red or dashed grey, respectively. When the slope is significantly different than zero the percentage of change over the time period is displayed in the top right corner.

Figure 16. Panel A: time series of reported harvest weight (t) and estimated harvest number of Atlantic Salmon in the Saint-Pierre and Miquelon fishery (ICES 2020). Panel B: estimated proportion by regional group of Atlantic Salmon sampled from the fishery catches based on microsatellites markers. Panel C: regional groups of Atlantic Salmon assigned using microsatellite markers. Figures in panels $B$ and $C$ are from ICES (2018).
