The work reported here was undertaken within the framework of an inter-departmental agreement between the Ministry of Environment, Conservation and Parks (MECP) of Ontario, and the National Research Council Canada (NRC). Project co-ordination support of Mr. Ted Belayneh from the MECP and technical assistance and review by Dr. Mohammad Sajjad Khan and Dr. Zhiping Yang also from the MECP is very much appreciated.

The assistance of Ms. Kathryn Glynn and Mr. Vaibhav Bhate from Carleton University with the five huge appendices that accompany this report is also appreciated. This report considerably benefitted from the R computing platform. Several individuals who maintain and contribute to this amazing platform are gratefully acknowledged. Mr. Jason Mills from the NRC provided editorial support, which is graciously acknowledged.

The technical detail and views expressed here are compiled based on the published literature and previously developed report on low flow characteristics of Ontario streams by Cumming Cockburn Limited, completed in 1990. Most of the low flow characteristics included in that report were derived using the low flow frequency analysis tool, commonly known as LFA. This tool was developed by Inland Waters Directorate (currently Water Survey of Canada) of Environment and Climate Change Canada. Most of the functionality of this tool is now implemented in Green Kenue, which is NRC's flagship software, often used as a pre- and post-processor to support hydrological modelling. This implementation was led by Mr. Alan Barton from the NRC. The FORTRAN code of the original tool was provided by Water Survey of Canada. The efforts of all individuals who were involved in the development of the original tool are gratefully acknowledged.

Executive Summary

In Ontario, analysis of low flows was conducted in 1990 by Cumming Cockburn Limited using observational records from over 340 gauging locations and a software package developed by Inland Waters Directorate (currently Water Survey of Canada) of Environment and Climate Change Canada (ECCC). As the software has become almost obsolete overtime due to tremendous changes in the underlying technology and roughly 35 years of additional data since the development of the report by Cumming Cockburn Limited, the Ministry of Environment, Conservation and Parks (MECP) of Ontario desired to have the software redeveloped in a modern language, along with a user-friendly interface, and all technical reports to be updated. The specific deliverables of the overall project conceived by the MECP were: (1) an updated low flow frequency analysis (LFFA) software, (2) a report pertaining to LFFA of Ontario streams using longer and most recent data, (3) development of a framework for undertaking LFFA considering the effects of future climate change, and (4) a documented review of regional LFFA techniques, with a focus on ungauged locations. The National Research Council Canada (NRC) headed this effort through an inter-departmental agreement between the MECP and the NRC. This report pertains to item 2 above and therefore contains updated information on low flow analysis for Ontario streams based on longer observational records, where available, from the entire hydrometric network managed by ECCC across Ontario. Theoretical information on data screening procedures and distribution fitting methods was derived mainly from the report prepared by Cumming Cockburn Limited and key technical documents that were referred to at the time. Some additional insights from the published literature that have become available since then are also considered. In the reports by Cumming Cockburn Limited, the analyses were organized based on five regional partitions of Ontario. The spatial demarcation of these regions is no longer available with the MECP and therefore five administrative regions of Ontario are used in this report to organize results of low flow analyses and to satisfy project objectives.

Low flow studies often require estimates of the magnitude, frequency, and duration of low flow events. When the duration of a low flow event is fixed (e.g. 5 or 7 days), which generally is the case, the analysis then simply involves estimation of the magnitude and frequency of low flow events by employing statistical frequency analyses and observational records from gauged locations. These analyses can be carried out at a single site or at the level of a specific region of interest, whether small or large. The main purpose of the latter approach is to improve the quality of selected low flow indices at gauged locations and to facilitate a framework for the estimation of the same indices at ungauged locations, where streamflow data are either limited or nonexistent within the region of interest. In the literature on low flow hydrology, this approach is generally referred to as regional low flow frequency analysis. This topic, based on the literature on low flow hydrology, is covered independently in a separate report. The focus of this report is on single site statistical frequency analysis of low flows in Ontario. In most cases, statistical frequency analysis involves fitting a probability distribution to a sample of low flow events. The output of this analysis gives an idea of the likelihood of occurrences of a specified low flow

event under some sensible assumptions. The events estimated so are used to support various management and environmental functions and societal needs, including domestic and industrial freshwater supplies and waste load allocations to streams.

This report is divided into four main chapters and a section on references. An introductory information on the subject of LFFA and the historical context of the project is provided in Chapter 1. Objectives and limitations of the report are also discussed in this chapter. Chapter 2 contains basic information on low flow concepts for riverine environments, study regions and streamflow data used for characterizing low flows in Ontario. The methodology for conducting at-site LFFA, data screening procedures and development of flow duration curves is also elaborated in Chapter 2, which is driven mainly by the work of Cumming Cockburn Limited and the references cited in there. Results of the study pertaining to data screening, frequency analysis and flow duration curves are presented and discussed in Chapter 3, along with selected examples from a much larger dataset. Detailed results of data screening, frequency analyses and annual and monthly flow duration curves are provided in Appendices A to E, corresponding to five administrative regions the province is divided into. Main conclusions of the study and insights gained from various analyses, included in this report, are summarized in Chapter 4. Some directions and recommendations for future studies are also presented in this chapter. A list of references cited in all chapters is available at the end of the report.

The information on low flow characteristics contained in this report is expected to help the MECP in fulfilling its provincial mandate and delivering superior service offerings to the industrial and domestic water users and wastewater dischargers in Ontario, in addition to supporting several environmental conservation projects across the province. Current estimates of low flow indices were derived from long-term observations and therefore reflect a more realistic picture of low flow conditions in Ontario streams. The recommendations provided in the last chapter of the report were gathered from the literature and they also reflect on the outcomes of two companion reports, as well as the author's vast experience of the domain. One of the companion reports is related to regional low flow frequency analysis and the other to climate change integration with low flow estimation techniques. The recommendations will help pave the way forward for improving estimation of low flow characteristics across Ontario and will also help uncovering geophysical and climatic controls on low flow regimes in Ontario in order to advance scientific knowledge and modelling capabilities.

1 Introduction

1.1 Background

In Ontario, analysis of low flows was conducted by Cumming Cockburn Limited (1990) more than 30 years ago using observational records from over 340 gauging locations and a software package developed by the Inland Waters Directorate (currently Water Survey of Canada) of Environment and Climate Change Canada (ECCC). The software has become obsolete overtime due to technological advancements and roughly 35 years of additional data since the completion of the study by Cumming Cockburn Limited. The Ministry of Environment, Conservation and Parks (MECP) of Ontario desired to have the software functionality redeveloped in a modern language, along with a user-friendly interface. Most of this is being integrated in Green Kenue, which is National Research Council Canada's (NRC) flagship software often used as a pre- and post-processor for hydrological applications. The specific deliverables of the project were identified as: (1) an updated low flow frequency analysis (LFFA) software, (2) a report pertaining to LFFA of Ontario streams using longer and most recent data, (3) development of a framework for undertaking LFFA considering the effects of future climate change, and (4) a documented review of regional LFFA techniques, with a focus on ungauged locations in Ontario. The NRC led this effort through an inter-departmental agreement between the MECP and the NRC. This report pertains to item 2 above and therefore contains updated information on low flow characteristics for Ontario streams based on a longer set of observational records from an expanded number of stations, managed by ECCC across Ontario. Detailed theoretical information on data screening procedures and statistical distribution fitting methods was derived mainly from the reports prepared by Cumming Cockburn Limited (1990) and some key references cited in there, with several additional insights from the published literature that has become available since then. In the reports by Cumming Cockburn Limited (1990), five regional partitions of Ontario were used to organize the results and the analyses were conducted separately for each of these regions. Compared to this strategy and to remain aligned with the main objectives of the project, in this report, the results are organized using five MECP administrative regions of Ontario provided by the ministry. These administrative regions are shown in Figure 2.2 in Chapter 2 of this report.

In riverine environments, a low flow condition can be defined as a period, ranging from a day to several days (e.g. 5 or 7 days or any other discrete number of days), during which the average streamflow is a minimum for the entire year or for a selected seasonal or sub-seasonal period, such as December to March winter months or June to August peak summer months. Probabilistic characterization of low flow conditions in riverine environments is essential for a number of engineering purposes and to satisfy many societal needs and natural environmental functions, such as determination of minimum flow requirements downstream of a hydropower plant, design of water storage facilities, quantification of available water resources to inform municipal and industrial usages, management of water quality to support riverine habitat, determining effluent

dilution capacity, assessing the impact of low flows on aquatic ecosystems and recreational facilities, etc.

Low flow studies often require estimates of the magnitude, frequency, and duration of low flow events. When the duration of a low flow event is fixed (e.g. 5 or 7 days), which generally is the case, the analysis then simply involves estimation of the magnitude and frequency of low flow events by employing statistical frequency analyses and observational records from gauged locations. These analyses can be carried out at a single site or at the level of a specific region of interest. The main purpose of the latter approach is to improve the quality of selected low flow indices at gauged locations and to facilitate a logical framework for the estimation of the same indices at ungauged locations, where streamflow data are either limited or nonexistent within the same region of interest. In the literature on low flow hydrology, this approach is generally referred to as regional low flow frequency analysis, which is covered independently in a companion report (i.e. Khaliq, 2021) in the context of ungauged hydrology. The focus of this report is on single site statistical frequency analysis of low flows in Ontario. In most cases, statistical frequency analysis involves fitting a probability distribution to a sample of low flow events, which are derived from historical observations using either the block minima or the partial-duration-series sampling approach. In the former case only one low flow event from a given year or season is considered while in the case of the latter approach, more than one event from the same year can be included in the sample. In some studies, the latter approach is also referred to as peaks-below-threshold (or crossings-below-threshold), which is just opposite the peaks-over-threshold (or crossings-above-threshold) approach used for high flow analysis. The output of statistical frequency analysis gives an idea of the likelihood of occurrences of a specified low flow event under some sensible assumptions. The events estimated so are used to support various management and environmental functions and societal needs as mentioned above.

Statistical frequency analysis is performed to derive desired indices of low flows using recorded observations from gauged locations. In doing so it is often assumed that the observed records are from a stationary climate. Due to climate change as projected by Global Climate Models (GCMs) and documented in various reports of the Intergovernmental Panel on Climate Change (IPCC) (IPCC, 2007, 2013), the assumption of a stationary climate has become questionable and therefore the applicability of low flow indices, derived from recorded historical observations, and their transposition at ungauged locations under the assumption of stationarity, has also become questionable. It is worth pointing out that many human related activities clearly affect the climate system. Most importantly, emissions of greenhouse gases, especially carbon dioxide and methane, are causing more heat to be trapped within earth's atmosphere. Therefore, the case for significant climate change is compelling in both the empirical observations and theoretical predictions. A warmer air mass can hold more water (i.e. the warmer air has a higher saturation vapor pressure) and therefore, it is reasonable to expect higher amounts of water vapor in the air, leading to the intensification of the hydrologic cycle, with impacts ranging from one region to

another and from one component of the hydrologic cycle to another (e.g. IPCC, 2013). However, it is not so straightforward to consider the impacts of a changing climate when deriving low flow indices for ungauged locations within a target region of interest. Although recognized and acknowledged here, the topic of non-stationary climate for LFFA remains outside the scope of this report. Data screening procedures are important for LFFA as they can provide some indications of non-stationary behaviour of observed low flow sequences, as well as insights on their serial structures. A framework for the estimation of low flow indices under the influence of climate change is discussed in a separate report (i.e. Khaliq, 2022), which was another deliverable of the project as indicated above.

1.2 Objectives of the Study

The main goal of this report was to document updated results of low flow frequency analyses for Ontario, based on longer datasets than originally used in the work of Cumming Cockburn Limited (1990), using the same statistical procedures as were implemented in the low flow frequency analysis (LFA) software tool developed by Inland Waters Directorate of ECCC (Condie and Cheng, 1983). The specific objectives of this report were to:

- Document results of data screening procedures by testing sequences of low flow events for independence, stationarity and general randomness as these are the fundamental assumptions that underpin applications of the conventional statistical frequency analysis procedure.
- Generate and organize updated information on low flow indices for Ontario, based on reasonable geographic partitions of the province, conceptually similar to the partitions used in the work of Cumming Cockburn Limited (1990).
- Generate and tabulate summaries of flow durations from monthly and annual flow duration curves, with the provision of flow duration curves in graphical forms for all hydrometric stations that are found suitable for the analysis, including all active and discontinued stations.
- Document potential avenues for future improvements for determining low flow characteristics in Ontario in order to enable the MECP in meeting its service delivery targets.
- Identify research directions that can be pursued in the future to uncover several other aspects of low flow sequences that can complement the results of this study, improve our understanding of low flow regimes in Ontario, and uncover inter-variable relationships from both physical and statistical perspectives.

1.3 Organization of the Report

This report is divided into four main chapters, including this introduction chapter, and a section on references. An introductory information on the subject of low flow frequency analysis and the historical context of the project is provided in Chapter 1. Objectives and limitations of the report are also discussed in this chapter. Chapter 2 contains basic information on low flow concepts, MECP administrative regions and streamflow data used for characterizing low flows in Ontario.

The methodology for conducting at-site LFFA, data screening procedures and developing flow duration curves is also elaborated in Chapter 2. The contents of this chapter are driven mainly by the work of Cumming Cockburn Limited (1990) and some key references cited in there. Selected outcomes of data screening procedures and frequency analyses and representative flow duration curves are presented in Chapter 3 for discussion purposes. Main conclusions of the study are summarized in Chapter 4, in addition to some directions and recommendations for future studies. A list of references cited in all chapters is available at the end of the report. The report also accompanies five appendices A to E, corresponding to each of the five administrative regions of Ontario. These appendices contain detailed results of data screening procedures, low flow frequency analyses and characteristics of annual and monthly flow duration curves.

1.4 Convention on the Usage of Acronyms and Other Considerations

A number of acronyms are used in this report, which are devised based on various acronyms used previously in the reports of Cumming Cockburn Limited (1990) and in the literature on hydrologic frequency analysis. Some of the acronyms are chapter-specific, while others are utilized throughout the report. Therefore, to facilitate easy comprehension and smooth readability, the acronyms are reintroduced in their expanded form in each chapter so that each chapter can be read independently. The same strategy was also used in preparing other reports, which were completed within the scope of the same project.

In this report, the terms like river flow, streamflow, or simply flow, reflecting open channel flow conditions, are considered equal in terms of meanings. It was necessary to state it upfront since differing terminologies are used in the literature on low flows. Selected exceedance points of flow duration curves from the lower portion of these curves and low flow magnitudes or quantiles corresponding to selected return intervals or return periods are referred to as low flow indices in this report. The terms like return value, return level and quantile corresponding to a certain return period or recurrence interval are equal in meanings and represent the same quantity. For a selected return period of interest (say 20 years), the corresponding return value is generally designated as “20-year return value” and sometimes as “1:20 or 1-in-20 year return value”. These are different conventions that have been used in the literature to refer to the same value and concept.

1.5 Scope and Limitations

The material provided in this report is meant to update the information provided in the report compiled by Cumming Cockburn Limited (1990). Therefore, the data screening and frequency analysis approaches are the same as discussed in this report and the references cited in there, especially the technical documents and papers prepared by the Inland Waters Directorate (currently Water Survey of Canada) of ECCC. Very similar data screening procedures are still

routinely used in hydrology, environmental sciences and other related disciplines. Compared to these procedures, the low flow frequency analysis area has seen several novel ideas and perspectives, particularly with respect to the choice of a statistical distribution function for at-site frequency analysis, regional estimation procedures, seasonality considerations, and estimation of flow duration curves at ungauged locations. Many of these aspects have been covered in two companion reports, i.e. Khaliq (2021, 2022), which were completed within the scope of the same project. For this report, no attempt was made to investigate and compare various distribution functions and their parameter estimation methods that are used in other parts of the world for low flow analyses, except those that were used in Cumming Cockburn Limited (1990). Exactly the same heuristic approach was used as reported in the LFA software tool developed by Inland Waters Directorate of ECCC (Condie and Cheng, 1983).

It is important to note that the scope of this report is limited to only hydrological aspects of low flows. The environmental aspects that are equally important for assessing and defining low flow magnitudes and thresholds to satisfy certain environmental needs of streams are outside the scope of this report. For a detailed account of these aspects, the reader is referred to appropriate published sources. To improve analysis and understanding of low flow regimes and their characteristics, some avenues of future research are identified based solely on author's vast experience of the domain and the guidance available in the literature on low flow hydrology, while attending to new developments and methodological advances. Detailed descriptions of theoretical aspects that underpin new developments in low flow hydrology are not covered in this report.

The consequences of climate change as documented in many reports of the IPCC has several ramifications for LFFA in Canada. Some perspectives on the integration of climate change information with LFFA procedures for Ontario are discussed in Khaliq (2022). These procedures require specific knowledge of climate change projections, global and regional climate modelling, and deterministic and stochastic hydrology. Therefore, these aspects are also not discussed in this report. Non-stationary frequency analysis is another area that is becoming popular for modelling changing patterns of hydrological extremes using covariate-dependent parameters or moments of distribution functions. Although very relevant and interesting to investigate, such approaches do not fall within the scope of this report.

2 Methodology

2.1 Background

For any given year at a gauged location, a low flow event can be defined as the annual minimum daily flow or it can also be defined in terms of an annual average low flow value that can persist over a period of d days, where d could be 3, 5, 7, 15, 30 or any other discrete number of days. The choice of d depends on the regulatory norms, mandated by watershed management authorities or government departments, and also on the objectives of the study, among many other factors. However, averaged flows for $d > 1$ -day are believed to be less sensitive to measurement errors (Shi et al., 2010). On an annual scale, there will be as many number of d -day low flows as there is the number of years of streamflow records at a given gauging station.

For conducting statistical frequency analysis of low flows at a given site, where continuous streamflow observations are available, one begins by extracting a sample of d -day low flows. After that a suitable statistical distribution (e.g. the lognormal distribution) is fitted using a parameter estimation method (e.g. the method of moments). The fitted distribution is used to define a return value-return period (i.e. $Q_T \sim T$) relationship at the site of interest. The return value Q_T is a flow that is expected to occur on average once in a T -year period. The reliability of the $Q_T \sim T$ relationship is highly dependent on the quality of the low flow sample used in developing this relationship. Therefore, before fitting a statistical distribution to a given sample of low flows, it is important to investigate the quality of low flow observations. For this purpose, it is important to know that the sample values have come from the same distribution and they are free from serial dependence and temporal trends, in addition to conforming to a random sample. Several statistical tests are available in the literature to verify these assumptions. In this report the same tests as were used in Cumming Cockburn Limited (1990) and implemented in the LFA software (Condie and Cheng, 1983) are retained. These tests are described in Section 2.3 of this chapter. In a similar manner, the same statistical distributions and parameter estimation methods are also retained in this report as were used in Cumming Cockburn Limited (1990); these are described in Section 2.4. The entire process of developing the $Q_T \sim T$ relationship and data screening are schematically shown in Figure 2.1. It is likely that each component process shown in this figure may in turn consists of several sub-processes. A general introduction to the dataset used in this report is provided in Section 2.2. Section 2.5 of this chapter contains information on flow duration curves, and how these curves are derived from a given set of observations.

Figure 2.1: A process diagram showing various steps involved in at-site frequency analysis, starting from site selection to parameter estimation of distribution functions, choice of the model and outcomes of the entire process.

2.2 Study Regions and Data

The objective of this report was to update low flow estimates for the entire province of Ontario, previously completed by Cumming Cockburn Limited (1990), using the same methodology as used previously and also considering the new data that has become available since then. The results of the previous assessment were organized on the basis of five regional partitions of Ontario. In the absence of spatial information of previously used regional partitions, five administrative regions of the Ministry of Environment, Conservation and Parks (MECP) are used in this report, i.e. the Northern, Central, Eastern, Southwestern, and West Central Regions (see Figure 2.2). The hydrometric data used in this study is sourced from Environment and Climate Change Canada’s (ECCC) HYDAT database via Green Kenue, which is National Research Council Canada’s (NRC) flagship software tool often used as a post- or pre-processor for hydrological applications. There are 795 hydrometric stations in Ontario where information on recorded flows is available. These stations include active, discontinued, regulated and non-regulated flow measuring stations, with continuous operational schedule. These stations are shown in Figure 2.2. The definition of a non-regulated station varies from one station to another and consequently some of these stations can be categorized as natural or near-natural pristine stations. For this report, the ‘non-regulated’ terminology is retained. When performing regional frequency analysis of low flows across Ontario, it will be necessary to identify hydrologic homogeneous regions based on natural or non-regulated flow measuring stations and therefore

some adjustments may need to be made to spatial extents of administrative regions used in this study.

Figure 2.2: Ontario’s administrative regions along with all active and discontinued flow measuring HYDAT stations with continuous operational schedule.

2.3 Data Screening Methods

This section briefly summarizes various statistical tests that were selected to screen observed samples of low flow values. These tests help understand the behavior of low flow values and provide indications whether the assumptions that underpin statistical frequency analyses (see Section 2.4) are satisfied or not. In particular, it is important to verify that a given sample of low flows consists of random observations that are not serially correlated and also do not exhibit linear or non-linear trends. It is also assumed that the observations are free of cyclic patterns. Here, the tests for independence, trend and general randomness are discussed. These tests are the same as were used in the work of Cumming Cockburn Limited (1990). All considered tests are of nonparametric type, i.e. the tests do not require any assumptions pertaining to the distributional form of low flow observations. The tests considered include the Spearman rank order correlation coefficient test for independence (Siegel, 1956); the Spearman rank order correlation coefficient test for trend (Siegel, 1956); and a general randomness test based on fluctuations of observations above and below the median (Siegel, 1956). The last test is also known as the turning point test of randomness. It was possible to consider additional statistical tests, but that option was not considered due to the scope of this report.

In general, any statistical test of significance consists of the following main steps (e.g. Haan, 1977; Walpole et al., 2011):

- A statement of the null hypothesis, H_0 . For instance, for the trend test, the null hypothesis may be that there is no trend in observations, i.e. observations are not systematically increasing/decreasing overtime.
- Selection of a significance level, α .
- Selection of an appropriate statistical test that satisfies the intended purpose of data screening. For example, Spearman rank order correlation test for trend.
- Calculation of the test statistic.
- Availability of the sampling distribution of the test statistic in the form of tables corresponding to the selected significance level, defining the region of rejection, or user-friendly computer routines providing the same.
- If the computed test statistic lies in the region of rejection, then the null hypothesis is rejected and it is concluded that there is not enough evidence to accept the null hypothesis based on the given sample of observations.

The tests considered for this report are described below in a systematic manner. As mentioned above, these tests were also considered in the work of Cumming Cockburn Limited (1990), which is being updated through this project. The results of these tests are discussed in Chapter 3 and only theoretical aspects of these tests are considered here. Most of the information provided here is directly sourced from this publication, corrected where necessary, and cross-validated with the information provided in the LFA and CFA (Consolidated Frequency Analysis) software manuals (Condie and Cheng, 1983; Pilon and Harvey, 1993).

2.3.1 The Spearman Rank Order Correlation Test for Independence

Let Q_i with i ranging from 1 to N is the longest consecutive chronological low flow series within the available record. Two sequences are created and ranks are assigned to the series, i.e.

$Q_1, Q_2, \dots, Q_{N-1} := x_i$, where x_i is the rank of the series Q_i , $i = 1$ to $N - 1$, and $Q_2, Q_3, \dots, Q_N := y_i$, where y_i is the rank of the series Q_i , $i = 2$ to N .

The Spearman rank order serial correlation coefficient is computed as:

$$S_1 = \left(\frac{1}{2}\right) [\Sigma x_i^2 + \Sigma y_i^2 - \Sigma d_i^2] [\Sigma x_i^2 \Sigma y_i^2]^{-1/2} \quad (2.1)$$

where

$$\Sigma x_i^2 = \frac{(m^3 - m)}{12} - \Sigma t_x \quad (2.2)$$

$$\Sigma y_i^2 = \frac{(m^3 - m)}{12} - \Sigma t_y \quad (2.3)$$

d_i is the difference in ranks between x_i and y_i , $m = N - 1$, and the summations are over the m pairs of x_i and y_i . Ignoring the terms in t and putting them equal to zero, Equation (2.1) becomes:

$$S_1 = 1 - \frac{6\Sigma d_i^2}{(m^3 - m)} \quad (2.4)$$

This is the more familiar form of the Spearman rank order correlation coefficient.

The terms in t adjust for tied ranks and are computed as follows. If for instance three observations in the x series are tied for ranks 17, 18, and 19 then each observation is given the rank 18; if two are tied for ranks 24 and 25, then each is given the rank 24.5. For each tied set, t is computed from:

$$t_x = (J^3 - J)/12 \quad (2.5)$$

where J is the number of observations tied at a give rank. Σt_x and Σt_y are defined in an analogous manner and represent summations over all tied groups. For $N \geq 10$, the statistic

$$t_s = S_1[(m - 2)/(1 - S_1^2)]^{1/2} \quad (2.6)$$

follows the Student's t distribution with $m - 2$ degrees of freedom (Siegel, 1956). For testing the statistical significance of the correlation, S_1 , a two-tailed test would be more appropriate compared to the one-tailed test used in Cumming Cockburn Limited (1990), since the sign of correlation is unknown before performing the test.

2.3.2 The Spearman Rank Order Correlation Test for Trend

Let Q_i , with i ranging from 1 to N , is the chronological low flow series, i.e. $Q_1, Q_2, \dots, Q_N := y_i$, where y_i is the rank of the series Q_i , $i = 1$ to N , and $1, 2, 3, \dots, N := x_i$, where x_i is the sequential order of Q_i in case of continuous data or the exact time points in case of missing observations.

The Spearman rank order correlation coefficient r_s for trend is calculated as in Equation (2.1), except that $m = N$, $t_x = 0$, and the summations are taken over the N pairs of x_i and y_i . For $N \geq 10$, the statistic

$$t_s = r_s[(N - 2)/(1 - r_s^2)]^{1/2} \quad (2.7)$$

follows the Student's t distribution with $N - 2$ degrees of freedom (Siegel, 1956). The null hypothesis is that there is no trend, either upward or downward with time, and so a two-tailed test is more appropriate.

2.3.3 Runs Above and Below the Median Test for General Randomness

This randomness test is based on the order or sequence in which the individual scores or observations were obtained. The test is based on the number of runs a sample exhibits. A run is defined as a succession of identical symbols which are followed and preceded by different symbols or by no symbols at all (Siegel, 1956; Conover, 1999).

The total number of runs in a sample of any given size gives an indication of whether or not the sample consists of random observations. If very few runs occur, a time trend or some bunching due to lack of independence is suggested. If a great many runs occur, it is likely that systematic short-period cyclical fluctuations may be influencing the sample.

Once the median of the sample is determined, each observation can be labelled as being above and equal to or below and equal to the median. If "A" represents above and equal to the median and "B" represents below and equal to the median, then a sample may be ordered as shown in the following example:

AABBBABBBBAABA

Here, a run represents a succession of identical symbols. For this example, each run is underscored and numbered consecutively as shown below:

$$\frac{AA}{1} \quad \frac{BBB}{2} \quad \frac{A}{3} \quad \frac{BBBB}{4} \quad \frac{AA}{5} \quad \frac{B}{6} \quad \frac{A}{7}$$

This sample begins with 2 observations above or equal to the median, followed by a run of 3 observations below or equal to the median, etc.

Seven runs are observed in this sample, i.e. the total number of runs above and below the median $RUNAB$ is 7. If n_1 represents the number of events of type A, then $n_1 = 6$. If n_2 denotes the number below the median, i.e. type B events, then $n_2 = 8$. The number of observations would be equal to $(n_1 + n_2)$.

In order to apply this runs test, one must determine n_1 , n_2 and $RUNAB$. The null hypothesis, H_0 , is that the A's and B's occur in random order. The alternate hypothesis, H_1 , is that the order of A's and B's deviates from randomness. When either n_1 or n_2 is greater than 20, the sampling distribution of $RUNAB$ tends to normality with:

$$z = \frac{|RUNAB - [(2n_1n_2)/(n_1 + n_2) + 1]|}{\{2n_1n_2(2n_1n_2 - n_1 - n_2)/[(n_1 + n_2)^2(n_1 + n_2 - 1)]\}^{1/2}} \quad (2.8)$$

where z is a standard normal, $N(0,1)$, variate. The null hypothesis of randomness is rejected at significance level $\alpha = 0.05$ ($\alpha = 0.01$) if z is greater than 1.96 (2.575). For smaller samples, exact critical values are available in Siegel (1956).

2.4 Low Flow Frequency Analysis

For performing low flow frequency analysis (LFFA) and developing the $Q_T \sim T$ relationship at the site of interest, a theoretical probability distribution function is fitted to the sample of low flows, using an acceptable method for estimating distribution parameters. Among the distribution functions that have previously been used in the literature on LFFA include the Weibull, gamma, lognormal, Pearson Type III, and Generalized Extreme Value distributions. Both the two- and three-parameter Weibull distributions have often been used for LFFA. In practice, several probability distributions are generally considered before picking a single distribution function based on some goodness-of-fit tests or a credible physical reasoning for national and large regional scale applications. For estimating parameters of these distributions from observed samples of low flows, several methods can be used, including the method of moments (MOM), method of maximum likelihood (MML or MAX), and method of L-moments (MLM). Compared to the commonly used MML abbreviation for the method of maximum likelihood, the MAX (reflecting ‘maximum likelihood’) abbreviation is retained here due to backward compatibility with the work of Cumming Cockburn Limited (1990). The MOM is easy to apply compared to the MAX method, however, the MAX method is statistically the most efficient method i.e. it provides asymptotically minimum variance estimators (Walpole et al., 2011). Compared to the MOM, the MAX method generally involves non-linear equations which often require numerical solutions or optimization techniques. Due to some attractive properties in terms of robustness for small samples and readily available computer code, the MLM has become quite popular in hydrology and environmental sciences for fitting distribution functions for frequency analysis of extreme values.

The main objective of this report was to update the low flow analyses presented in Cumming Cockburn Limited (1990). Therefore, in order to be consistent with the objective of this report, the same distribution functions and parameter estimation methods as were used in Cumming Cockburn Limited (1990) were considered. These distributions and parameter estimation procedures are described below; the description is derived mainly from this source and the relevant references cited in there. Where deemed necessary the information derived is modified, with guidance from the recent literature. It is important to note that no efforts were made to find other statistical distributions and parameter estimation procedures (e.g. Yue and Pilon, 2005) that might be more suitable than the ones described here following Cumming Cockburn Limited (1990) and the references cited in there.

2.4.1 The Gumbel Type III Distribution

This is a variation of Fisher and Tippett's third asymptotic distribution of extreme values and is sometimes referred to as the Weibull distribution. In view of Gumbel's many contributions, it is often referred to in hydrology as the Gumbel III distribution. The probability density function (PDF) of this distribution is given by:

$$f(x) = \frac{a}{u - e} \left\{ \frac{x - e}{u - e} \right\}^{a-1} \exp \left[- \left\{ \frac{x - e}{u - e} \right\}^a \right] \quad (2.9)$$

where e is the lower bound or the location parameter, u is referred to as the characteristic drought and a is the shape parameter. In another equivalent notation, $u - e$ is replaced by, e.g., b and is termed as the scale parameter of the distribution. Various methods are available for determining the distribution parameters for a given sample. Based on earlier comparative studies, especially those completed by Inland Waters Directorate (IWD) (Condie and Cheng, 1983; Pilon and Jackson, 1988), the MOM, the MAX method and the method of smallest observed drought (SOD) were recommended. In the original LFA software developed by IWD (Condie and Cheng, 1983) and used in Cumming Cockburn Limited (1990), the order of preference for parameter estimation is MAX, followed by SOD and MOM. As long as the MAX method satisfies the data based physical requirement that the parameter e has to be smaller than the minimum observed low flow value included in the sample, the SOD method and the MOM are not considered. Subsequent studies (e.g. Hosking and Wallis, 1997) have suggested that the MAX method is specifically sensitive to small samples and can result in an erratic behaviour leading to unreasonable parameters. In such situations, the MLM can be a reasonable alternative for estimating parameters of the Gumbel III distribution. The MLM method is not considered here.

The probability density function $f(x)$ of the Gumbel III distribution is integrable and therefore the cumulative distribution function (CDF) exists in a closed form relationship, i.e.

$$F(x) = 1 - \exp \left[- \left\{ \frac{x - e}{u - e} \right\}^a \right] \quad (2.10)$$

which is the probability of observing a value less than and equal to x , often termed as the probability of non-exceedance. Since it is more common to require x for a given probability of non-exceedance, a simple re-arrangement of the CDF gives

$$x = e + (u - e) \left\{ - \ln [1 - F(x)] \right\}^{1/a}. \quad (2.11)$$

This relationship is commonly known as the quantile function and the variable x is the target in all low flow frequency analysis studies. Since x is estimated corresponding to a given value of $F(x)$, it is often notated as $x(F)$ to convey this concept. In low flow frequency analyses, the return period T and F are related by $T = 1/F$.

Parameter Estimation

The MOM estimates of the Gumbel III distribution can be obtained by equating theoretical relationships of mean, standard deviation and coefficient of skewness to corresponding sample estimates, rearranging the resulting equations and solving the following set of equations:

$$g_1 = \frac{\Gamma(1 + 3/a) - 3\Gamma(1 + 2/a)\Gamma(1 + 1/a) + 2\Gamma^3(1 + 1/a)}{[\Gamma(1 + 2/a) - \Gamma^2(1 + 1/a)]^{3/2}} \quad (2.12)$$

$$e = \bar{x} - s \frac{\Gamma(1 + 1/a)}{[\Gamma(1 + 2/a) - \Gamma^2(1 + 1/a)]^{1/2}} \quad (2.13)$$

$$u = \bar{x} + s \frac{1 - \Gamma(1 + 1/a)}{[\Gamma(1 + 2/a) - \Gamma^2(1 + 1/a)]^{1/2}} \quad (2.14)$$

where \bar{x} , s and g_1 respectively are the sample mean, standard deviation and coefficient of skewness; $\Gamma(\cdot)$ is the gamma function whose values are obtained from published tables or estimated numerically using the computer code. Often unbiased estimates of s and g_1 are used (Haan, 1977) and the same were adopted in this study. For earlier applications, the solution of Equation (2.12) was provided by Gumbel (1958) in a tabular form. However, it can be approximated within an accuracy of 1% using the following set of equations and guidance (Condie and Cheng, 1983):

for $-1.02 < g_1 < 1.80$,

$$1/a = 0.2778 + 0.3133g_1 + 0.05757g_1^2 - 0.001304g_1^3 - 0.008152g_1^4, \text{ and} \quad (2.15)$$

for $1.80 < g_1 < 3.80$,

$$1/a = 1.27421 + \ln(0.58452g_1 + 1.02291). \quad (2.16)$$

Knowing $1/a$ from the above equations, Equations (2.13) and (2.14) can be evaluated to obtain e and u , respectively. The polynomial equations for $1/a$ for a greater range of g_1 are available in Pilon and Harvey (1993). Equation (2.12) can also be solved using iterative algorithms.

The likelihood function L of $f(x)$ for a sample of size n is given by:

$$L = \prod_{i=1}^n f(x_i) = \prod_{i=1}^n \frac{a}{u-e} \left\{ \frac{x_i - e}{u - e} \right\}^{a-1} \exp \left[- \left\{ \frac{x_i - e}{u - e} \right\}^a \right] \quad (2.17)$$

It is easy to work with the logarithm of the likelihood function L , which is commonly referred to as the log-likelihood function in the literature and is given by:

$$\begin{aligned} \ln(L) = n \ln(a) - n \ln(u - e) + (a - 1) \sum_{i=1}^n \ln(x_i - e) \\ - n(a - 1) \ln(u - e) - (u - e)^{-a} \sum_{i=1}^n (x_i - e)^a \end{aligned} \quad (2.18)$$

The parameters of the Gumbel III distribution by this method are obtained either by maximizing $\ln(L)$ for the given sample or by equating partial derivatives of $\ln(L)$ with respect to u , e and a

to zero and then solving the resulting nonlinear equations. In general, it is difficult to have closed form relationships and therefore iterative procedures or optimization routines are often used to estimate parameters. For this distribution, the following equations can be obtained after some rearrangements (cf. Condie and Cheng, 1983):

$$n(u - e)^a - \sum_{i=1}^n (x_i - e)^a = 0 \tag{2.19}$$

$$-(a - 1) \sum_{i=1}^n \frac{1}{(x_i - e)} + \frac{an \sum_{i=1}^n (x_i - e)^{a-1}}{\sum_{i=1}^n (x_i - e)^a} = 0 \tag{2.20}$$

$$\frac{n}{a} + \sum_{i=1}^n \ln(x_i - e) - \frac{n \sum_{i=1}^n [(x_i - e)^a \ln(x_i - e)]}{\sum_{i=1}^n (x_i - e)^a} = 0 \tag{2.21}$$

By denoting Equation (2.20) by $f(a, e) = 0$ and Equation (2.21) by $g(a, e) = 0$, Condie and Cheng (1983) explained the solution of these two simultaneous transcendental equations graphically as shown in Figure 2.3.

Figure 2.3: Schematic depiction of the iterative procedure for estimating parameters of the Gumbel III distribution using the maximum likelihood method. Figure adapted from Condie and Cheng (1983).

In the iterative procedure, the root is first located within a separation interval of $0.1x_{min}$, where x_{min} is the minimum sample value. A Newton-Raphson method is used to solve $f(a, e)$ and $g(a, e)$ for a at $e = 0.999x_{min}$. The equations are then solved successively at 0.9, 0.8, 0.7, etc., of x_{min} and at each step the a values are compared until the separation interval is found. Once an interval is found, the same procedure can be repeated by successively decreasing the separation interval until a predefined convergence tolerance is satisfied. The separation intervals can also be formed using other logical means, e.g. by successively subtracting various multiples of the sample standard deviation from the x_{min} value. If the solution exists, this procedure converges within a small number of iterations. In low flow analysis procedures implemented in the LFA software (Condie and Cheng, 1983), it is assumed that the MAX method will provide a value of

e , which will be smaller than x_{min} . If this is not the case then it is assumed that this method does not provide a valid set of parameter values. Condie and Cheng (1983) suggest the procedure of Figure 2.3, while moving from right to left. The penultimate value of a (i.e. a_1) from $g(a, e) = 0$ is substituted in Equation (2.20) and solved to give e_1 , again by the Newton-Raphson method. Proceeding in this way, e_1 will give a_2 from Equation (2.21), which will in turn give e_2 from Equation (2.20). This procedure is continued until closure to a convergence tolerance, e.g. no change is observed in the 4th decimal place of e . Knowing e and a , Equation (2.19) is solved to obtain u .

According to Condie and Cheng (1983), Gumbel (1963) used the probability function of the smallest drought in n years, along with the mean and standard deviation of the distribution, to come up with the following three relationships:

$$\frac{(\bar{x} - x_{min})}{s} = \frac{(1 - n^{-1/a})\Gamma(1 + 1/a)}{[\Gamma(1 + 2/a) - \Gamma^2(1 + 1/a)]^{1/2}} \quad (2.22)$$

$$e = x_{min} - \frac{(\bar{x} - x_{min})}{(n^{1/a} - 1)} \quad (2.23)$$

$$u = \frac{\bar{x} - e}{\Gamma(1 + 1/a)} + e \quad (2.24)$$

The second term on the right-hand side of Equation (2.23) can never be negative and therefore by this method e can never exceed x_{min} . Thus, one of the conditions for an acceptable lower bound suggested by Condie and Cheng (1983) will always be satisfied. However, there is no guarantee that e will be greater than zero and therefore negative values of e are possible. The positive condition will only be met if $\bar{x}/x_{min} < n^{1/a}$ (Condie and Cheng, 1983). Equation (2.22) can be solved by a bisection method. According to Condie and Cheng (1983), the interval $a = 0.16$ and $a = 5.0$ was tested for a sign change and generally a was found to lie in this range. A small number of bisections can lead to a closure to a predefined tolerance level (e.g. 0.00002). In case of a failure, larger intervals can be searched by successively increasing the range to 10, 15, 20, etc., until a solution is found. Linear interpolation within the last interval can give the root to the desired decimal place (e.g. fifth decimal place). After knowing a , Equation (2.23) is evaluated to obtain e and then u is obtained from Equation (2.24).

2.4.2 The Three-Parameter Lognormal Distribution

There are occasions when the sample of low flows can have a large negative coefficient of skewness. For such samples, the Gumbel III distribution is not suitable and therefore Condie and Cheng (1983) recommended the negatively skewed three-parameter lognormal distribution as an acceptable alternative to the Gumbel III distribution.

If $y = \ln(a - x)$ is normally distributed, then the probability density function of x is given by

$$f(x) = \frac{1}{(a - x)\sigma\sqrt{2\pi}} \exp\left\{\frac{-1}{2\sigma^2} [\ln(a - x) - m]^2\right\} \quad (2.25)$$

where m and σ are respectively the mean and standard deviation of the series y and a is the boundary parameter. This form of the distribution can only have negative skewness and is upper bounded. The $f(x)$ equation in the form of $\ln(x - a)$ is for the distribution with positive skewness.

Taking moments, re-arranging the resulting equations and replacing distribution moments by their sample estimates gives:

$$k^3 + 3k - g_1 = 0 \quad (2.26)$$

where g_1 is the sample coefficient of skewness. After solving for k iteratively, other parameters of the distribution can be obtained by:

$$a = \bar{x} - s/k \quad (2.27)$$

$$m = \ln\left(-\frac{s}{k}\right) - \frac{1}{2}\ln(k^2 + 1) \quad (2.28)$$

$$\sigma = [\ln(k^2 + 1)]^{1/2} \quad (2.29)$$

After estimating parameters, the distribution is completely defined and the T -year low flow Q_T can be computed from:

$$Q_T = a - \exp(m - \sigma z) \quad (2.30)$$

where z is the standard normal deviate, with zero mean and unit standard deviation.

2.5 Flow Duration Curves

A flow duration curve (FDC) is a plot of the flow of a stream against the percent of time the indicated flow equalled or exceeded over the period of available record. This curve is extremely useful for hydropower studies, water allocations, characterizing local streamflow regimes, low flow assessments, determining environmental flows, and several other ecological and environmental functions.

For a given station or site, the FDC is derived by rearranging the available daily flow data in order of magnitude, i.e. in a descending order, and assigning a plotting position to each flow value. Several plotting position formulas are available in the literature and they generally differ

in extreme tails. Following Helsel and Hirsch (2002), Cunnane plotting position formula (Cunnane, 1978) was used for generating FDCs for this report. This formula is given by:

$$pp(i) = \frac{(i - 0.4)}{(n + 0.2)} \quad (2.31)$$

where i is the rank and n is the number of data points. The $pp(i)$ plotting position values lie between zero and unity. As the total records represent 100% of the time, the largest value is exceeded zero percent of the time and the smallest value is exceeded 100% of the time by definition of the FDC. For this report, the flow values corresponding to 0 to 100% exceedance points at an interval of 1% were required. Following the same strategy as used in Cumming Cockburn Limited (1990), the largest value is assumed to occur at the 0% exceedance point and the smallest at the 100% exceedance point. The values at 1 to 99% exceedance points were obtained using linear interpolation between the two closest points to the point of interest. It is important to note that some studies (e.g. Shu and Ouarda, 2012) have suggested performing interpolation within the log domain. This is particularly useful when the interest lies in the extreme upper tail where the method of interpolation is a bit sensitive due to lack of observations and larger differences between adjacent values. This issue becomes even more important when the sample size is quite small. For the lower end of the FDC, the logarithmic method will fail due to the presence of several zero flows, which is the case for several small streams and therefore the logarithmic interpolation is not considered. In addition, the differences between the two methods of interpolation were generally found at the third decimal point for the range of exceedance points considered in this report.

The period of record FDC represents the percent of time that a specific flow occurred or exceeded at a given location and therefore does not indicate the period or season of the year when the flow was less/greater than or equal to the selected value. Consequently, in some instances, it is also useful to develop FDCs separately for each month or season of the year, in addition to the overall period of record FDC. For this purpose, all data for the month of interest (i.e. January, February, March, April, etc.) over the entire period of record is analyzed independently to produce a FDC, which is assumed to be representative of flow conditions for that month. Following the above procedures, FDCs were determined for every station, and summaries of flow durations in the form of tables were also produced. To differentiate between the overall FDC and the ones corresponding to each of the 12 months, the former is referred to as the annual FDC and the latter as the monthly FDCs. Although a bit misleading, this report retains the same terminology as was used in the work of Cumming Cockburn Limited (1990), since the objective of this study was to update existing FDCs based on longer datasets compared to what was used in Cumming Cockburn Limited in 1990. This strategy will also offer backward compatibility. Sample of FDCs representative of regulated and non-regulated or natural flow regimes for selected watersheds are discussed in Chapter 3.

3 Results

3.1 General

The entire Water Survey of Canada daily streamflow HYDAT database (<https://collaboration.cmc.ec.gc.ca/cmc/hydrometrics/www/>; Hydat_sqlite3_20211019.zip) for the Province of Ontario for the period of record until the end of 2020 was considered for this study. Stations with a minimum of ten years of record were considered to have an appropriate record length for at-site frequency analysis documented in this report. Compared to this, stations with at least five years of continuous flow data were considered for flow duration analyses, i.e. for the development of flow duration curves and for generating summary tables. Following recommendations from the Ministry of Environment, Conservation and Parks (MECP), all active, discontinued, regulated and non-regulated stations were considered, without imposing any restrictions as was done in the analysis conducted by Cumming Cockburn Limited (1990). This consideration resulted in hundreds of additional stations compared to just over 340 stations used before in Cumming Cockburn Limited (1990). Since the availability of flow records for the entire year plays a significant role in representing seasonal patterns within the flow duration and extreme value analyses, any year with greater than and equal to 30% missing values was not included in the analysis. The lists of stations that satisfy these requirements are provided in Appendices A to E, respectively for the Northern, Central, Eastern, Southwestern and West Central Regions of Ontario.

For low flow frequency analyses, 1-, 3-, 7-, 15-, and 30-day duration annual minimum values for the January to December period were considered in order to be consistent with the approach adopted in Cumming Cockburn Limited (1990). Screening of resulting samples was carried out as explained in Chapter 2 and by performing all tests at both 1% and 5% significance levels. Additional detail is provided in Section 3.2 of this chapter. Extreme value analysis was conducted following exactly the same methodology as explained in Chapter 2, which in turn is the same methodology that was used in the report by Cumming Cockburn Limited (1990) and implemented in the low flow analysis (LFA) software (Condie and Cheng, 1983). See Section 3.3 for additional details on extreme value analyses. Development of flow duration analyses was undertaken using daily flows on both an annual and a monthly basis for the period of record, following the above discussed record length and missing value constraints. See Section 3.4 for additional details on flow duration analyses. In most cases, results from extreme value analyses would be used for characterizing low flows at a given station. However, under certain conditions, flow duration results can complement the results of frequency analyses, especially for heavily regulated stations.

3.2 Data Screening

Low flow samples were screened for serial correlation, monotonic trend and randomness following the methods described in Chapter 2. These results are provided in Appendices A to E, respectively for the Northern, Central, Eastern, Southwestern and West Central Regions of Ontario for all stations and for individual samples of 1-, 3-, 7-, 15-, and 30-day duration low flows. A quick summary of these analyses is presented in Table 3.1 with respect to regulated and non-regulated flow regimes for all stations, including active and discontinued stations. There are a considerable number of samples which are impacted by serial dependence, presence of trend and lack of randomness, specifically for the Northern, Central, Southwestern and West Central Regions. The percentage of such cases is higher for stations with regulated flow regimes than for stations with non-regulated flow regimes, since these stations will be more useful for assessing influences of climate change or other changes that might have occurred overtime. A further granularity on these analyses is provided in Table 3.2, by considering active stations with non-regulated flow regimes. There are several samples which are impacted by serial dependence for three (Northern, Central and West Central) regions; the same is applicable for the case of trends for all five regions. The number of such cases appear to be larger than what can be expected by chance. Negative (positive) serial correlations were found in 13, 19, 37, 33, and 21% (87, 81, 63, 67, and 79%) of samples, respectively, for the Northern, Central, Eastern, Southwestern and West Central Regions. In the same order, negative (positive) trends were found in 56, 26, 52, 20, and 30% (44, 74, 48, 80, and 70%) of samples.

Table 3.1: Percentage of low flow samples where null hypothesis of independence, absence of trend and randomness was rejected at two significance levels (i.e. 1% and 5%) for stations with regulated and non-regulated flow regimes for Northern, Central, Eastern, Southwestern and West Central Regions of Ontario.

Flow regime	Independence		Trend		Randomness	
	1%	5%	1%	5%	1%	5%
Northern						
Regulated	27.1	41.5	27.1	38.3	22.0	22.0
Non-regulated	10.1	19.8	8.4	17.1	8.2	8.2
Central						
Regulated	31.6	42.8	32.4	48.0	26.8	26.8
Non-regulated	11.1	23.8	27.9	38.1	13.7	13.7
Eastern						
Regulated	9.2	18.5	18.8	32.3	9.2	9.2
Non-regulated	2.6	4.9	7.2	19.2	5.7	5.7
Southwestern						
Regulated	33.8	42.6	44.6	51.3	19.0	19.0
Non-regulated	8.0	10.8	13.8	27.1	5.2	5.2
West Central						
Regulated	27.2	34.4	50.0	64.4	27.2	27.2
Non-regulated	7.7	10.3	12.3	25.2	3.2	3.2

Table 3.2: Percentage of low flow samples where null hypothesis of independence, absence of trend and randomness was rejected at two significance levels (i.e. 1% and 5%) for active stations with non-regulated flow regimes for Northern, Central, Eastern, Southwestern and West Central Regions of Ontario.

Region	Independence		Trend		Randomness	
	1%	5%	1%	5%	1%	5%
Northern	12.1	22.4	8.6	17.1	10.8	10.8

All results for those stations where low flow samples are found to be impacted by serial correlation, trend or lack of randomness should be carefully interpreted. Although approaches do exist for pre-processing these samples and then performing frequency analyses to derive desired results, such treatments were not included in the scope of this project. For such cases, it will be useful to investigate FDC based exceedance points to support decision-making for the management of low flow conditions. A large number of stations is regulated across Ontario. Consequently, low flow samples from these stations are impacted by anthropogenic influences and do not represent natural or near-natural flow conditions. Therefore, the use of corresponding low flow indices for planning purposes should be properly understood.

3.3 Low Flow Frequency Analyses

Low flow frequency analyses were conducted following the recommendations from Condie and Cheng (1983) which were implemented in the original LFA software (Condie and Cheng, 1983). The recommendations were translated in the form of a decision support system. As described in Chapter 2, three different parameter estimation methods, i.e. the maximum likelihood (MAX) method, the method of smallest observed drought (SOD) and the method of moments (MOM), were considered for the Gumbel III distribution and only the MOM for the three-parameter lognormal distribution. For a given sample of low flows, the Gumbel III distribution was fitted using the MAX method. If this method failed to produce the lower bound parameter smaller than the observed minimum value of the sample then the SOD method was tried which was guaranteed to produce a lower bound parameter smaller than the observed minimum value. The MOM was used if the SOD method failed to converge. For low flow samples with large negative skewness, the three-parameter lognormal distribution with the MOM was used for estimating low flow quantiles, since the Gumbel III distribution is not a suitable choice for such samples. In some cases, the MAX and the SOD methods produced negative values of the lower bound parameter. In such situations, the Gumbel III distribution produced negative return values corresponding to longer return periods (e.g. 100, 200 or 500 years). Since the low flow quantiles cannot be negative, these cases are identified using the NA (not applicable) identifier. In this report, the results of frequency analyses are presented separately in Appendices A to E,

corresponding to the five administrative regions of Ontario, respectively the Northern, Central, Eastern, Southwestern and Western Central Regions. Both tables and extreme value graphics are included in these appendices. Also, basic statistics (i.e. mean, standard deviation, coefficient of skewness, coefficient of variation and the observed minimum value of the low flow sample) and return values corresponding to selected return periods (i.e. 1.005, 1.010, 1.111, 1.250, 2, 5, 10, 20, 50, 100, and 200 years) are listed in tables. There is one table for each of the considered low flow durations. In the extreme value graphics, Cunnane plotting position formula (Cunnane, 1978) was used to plot observed low flow values.

The stations with less than 10 years of record were excluded from the extreme value analysis. Also, the stations with less than five years of non-zero low flow values were excluded from the analysis due to high uncertainties associated with the estimated distribution parameters. Information on the number of available stations for extreme value analyses for each of the five administrative regions is included in the preamble part of each of the five appendices.

Low flow values corresponding to longer return periods (e.g. 100, 200 and 500 years) are rarely used in low flow related studies. As the objective of this study was to update the existing analyses reported in Cumming Cockburn Limited (1990), the same convention as was used in these analyses was retained, i.e. the frequency analyses results are tabulated until 200-year return period and plotted until the 500-year return period.

The percentage of Gumbel III (GIII) cases with the MAX, SOD and MOM parameter estimation options are shown in Table 3.3. The three-parameter lognormal (LN3) cases are also listed in this table. The West Central Region shows the highest number of MAX cases (in %) followed by the Northern, Central, Southwestern and Eastern Regions. The percentage of SOD cases is the highest for the Eastern Region, followed by the Southwestern, Northern, West Central and Central Regions. The number of MOM cases for both the GIII and LN3 distributions are very small, mostly around 1–2% but not exceeding 3.5%.

Table 3.3: Percentage of samples that were fitted with the Gumbel III (GIII) distribution using three parameter estimation methods (i.e. MAX, SOD and MOM) and the three-parameter lognormal (LN3) distribution with the MOM for each of the five low flow durations and all durations together for five administrative regions of Ontario.

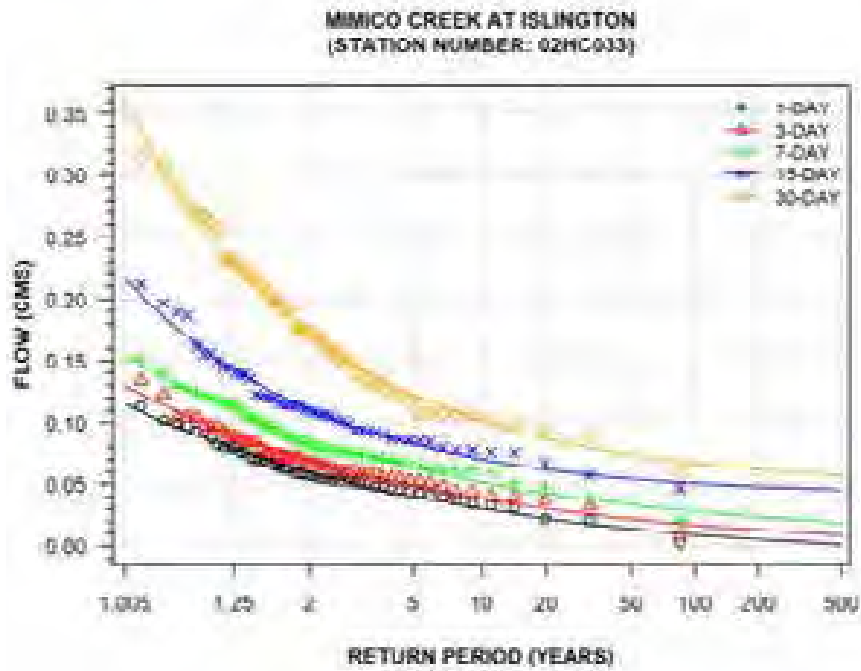

Method	Low flow duration					Total
	1-day	3-day	7-day	15-day	30-day

Extreme value plots for two selected stations, with non-regulated flow regimes, are shown in Figure 3.1, while for two regulated stations in Figure 3.2. It is important to note that caution should be exercised while interpreting results for regulated stations. These examples reflect typical behaviour of extreme value plots, while considerable deviations from this behaviour can be noticed for several stations included in Appendices A to E. Extreme value plots for two stations, reflective of samples containing recorded zero flows, are shown in Figure 3.3. In all figures, the ordinate units are in CMS, which stands for cubic meter per second.

As desired by the MECP and to complement the results of low flow frequency analyses at the annual time scale, low flow frequency analyses were also conducted for each month of the year for 7-day duration average minimum flows, following the same procedure as used for the annual time scale. Tables containing return values corresponding to selected return periods (i.e. 1.005, 1.010, 1.111, 1.250, 2, 5, 10, 20, 50, 100, and 200 years), along with basic statistics, and graphical plots are included in Appendices A to E, respectively for the Northern, Central, Eastern, Southwestern and West Central Regions of Ontario. For these analyses, representative sample plots are not presented in this section and the reader is referred to these appendices. The graphical plots are quite intuitive for identifying periods of relatively higher low flows when considering the annual cycle of 7-day duration monthly low flows.

3.4 Annual and Monthly Flow Duration Curves

The daily flow data was used for each station to derive empirical flow duration curves. The period of record flow duration curve for the entire year is termed annual flow duration curve while the ones corresponding to each of the twelve months as monthly flow duration curves. These curves can be summarized both numerically and graphically for each station. Tabular summaries were prepared separately for each station and they include the equalled or exceedance points at 1% intervals for the whole flow duration curve. These summaries are provided in Appendices A to E for each of the five administrative regions, i.e. Northern, Central, Eastern, Southwestern and West Central Regions. In these appendices, graphical output is provided for both annual and monthly flow duration curves. Figure 3.4 shows typical flow duration curves for stations with non-regulated flow regimes, while Figure 3.5 shows the same for highly regulated stations. For a detailed look at the lower portion of the flow duration curve, which is important in case of low flow analysis, a logarithmic scale can be advantageous for stations where non-zero flows are generally experienced. Monthly flow duration curves for the same two stations with non-regulated flow regimes is provided in Figure 3.6 while those for regulated flow regimes are provided in Figure 3.7.

4 Summary and Recommendations

4.1 Overview and Summary

In Ontario, analysis of low flows was conducted in 1990 by Cumming Cockburn Limited using observational records from over 340 gauging stations located across the province and a software package developed by Inland Waters Directorate (currently Water Survey of Canada) of Environment and Climate Change Canada. In this report, an update to this work is documented using a much larger network of hydrometric stations that included all active, discontinued, regulated and non-regulated stations, with continuous schedule, located across Ontario and observational records until the year 2020. This study, which is part of a bigger project, was completed within the framework of an inter-departmental agreement between the Ministry of Environment, Conservation and Parks (MECP) of Ontario and the National Research Council Canada. The theoretical information on data screening procedures and distribution fitting methods for low flow analysis were derived mainly from the work of Cumming Cockburn Limited (1990) and the technical documents that were consulted at the time. The results of all new analyses are organized based on five administrative regions of Ontario, provided by the MECP (cf. Figure 2.2).

This report is comprised of four main chapters and five comprehensive appendices that contain detailed outputs of all analyses. An introductory information on the subject of low flow frequency analysis (LFFA) and the historical context of the project is provided in Chapter 1, along with specific objectives and limitations of the report. Chapter 2 contains basic information on low flow concepts for riverine environments, the study regions—administrative regions, and streamflow data used for characterizing low flows in Ontario streams. The methodology for conducting at-site LFFA, data screening procedures and development of flow duration curves is also elaborated in Chapter 2, which is driven mainly by the work of Cumming Cockburn Limited (1990) and the references cited in there. Of primary importance are two distribution functions, i.e. the Gumbel Type III (GIII) distribution and the three-parameter lognormal (LN3) distribution and three parameter estimation methods, i.e. the method of maximum likelihood, the method of smallest observed drought and the method of moments. These parameter estimation methods are represented by three letter abbreviations, i.e. MAX, SOD and MOM, respectively, to ensure backward compatibility with the work of Cumming Cockburn Limited (1990). Based on a comparative evaluation of a limited number of distribution functions and parameter estimation methods, Condie and Cheng (1983) recommended the GIII-MAX distribution and parameter estimation method combination for low flow analysis in Canada and the same was the preferred choice for low flow analysis in Ontario (Cumming Cockburn Limited, 1990). These authors recommended the LN3-MOM combination for samples with large negative skewness and the GIII-SOD combination for samples for which GIII-MAX combination did not provide a valid solution. The MAX method for the GIII distribution was recommended because it is statistically

the most efficient parameter estimation method (e.g. Severini, 2000; Walpole et al., 2011). For a given sample of low flows, the SOD method is guaranteed to produce a lower bound threshold which is smaller than the minimum observed low flow value of the sample. This was a physical constraint against which the distribution and parameter estimation methods were judged by Condie and Cheng (1983). Based on their empirical experience with low flow sequences in Canadian streams, they recommended an automated straightforward decision support system (DSS) for performing low flow analysis. According to this DSS, if the GIII-MAX combination does not produce a valid lower bound threshold for a given dataset, then the estimation procedure should utilize the GIII-SOD combination. In case of unacceptable lower bounds or convergence related issues, the GIII-MOM combination should be used. In this report, exactly the same DSS was used for generating updated information on low flow indices corresponding to selected return periods (i.e. 1.005, 1.010, 1.111, 1.250, 2, 5, 10, 20, 50, 100, and 200 years), considering 1-, 3-, 7-, 15-, and 30-day duration average annual low flows. It is important to note that no additional distribution functions and parameter estimation methods were investigated in this report apart from those mentioned above. Some insights on these aspects can be found in Hosking and Wallis (1997), Smakhtin (2001), Yue and Pilon (2005) and Tallaksen and van Lanen (2004).

The results of the study pertaining to data screening, frequency analysis and development of flow duration curves are presented and discussed in Chapter 3, along with a few selected representative examples from a much larger network of stations. Detailed results of data screening, frequency analyses and annual and monthly flow duration curves are provided in Appendices A to E, corresponding to five administrative regions the province is divided into, i.e. the Northern, Central, Eastern, Southwestern and West Central Regions (cf. Figure 2.2). Some salient features of the reported analyses are highlighted below:

- For performing LFFA, availability of at least ten years of daily flow records was used as a threshold for a station to be included in the analysis. Given this threshold, only those stations were considered where at least five non-zero low flow values were available. For the development of flow duration curves, record length threshold was lowered to five years of available records after consultations with the MECP. For any year to be included in the analysis, missing value threshold was set at 30%, i.e. any year reporting greater than and equal to this many missing values was excluded from the analysis. These thresholds were used to satisfy two goals, one was to consider maximum number of stations to cover the entire province, desired by the MECP, and the second was to conquer reliability aspects of generated results, which is an important aspect for the applicability of all derived low flow indices.
- The results of data screening procedures show that a significant number of stations failed the nonparametric tests of independence, trend and randomness. Therefore, the samples of low flow extremes may exhibit lack of independence, presence of monotonic trends and

possibility of non-randomness. These features contradict the assumptions that underpin LFFA. The results of all analyses for these stations are retained in this report. As a word of caution, care must be exercised when interpreting low flow return values from those stations which suffer from such peculiarities. Additional investigations of the reasons, whether climatic or non-climatic, behind these features were beyond the scope of this study. One explanation could be due to the inclusion of low flow samples with short records which may not be suitable for detecting changing patterns, potentially driven by climatic and anthropogenic influences. Future investigations should concentrate on pristine stations where relatively longer records are available for arriving at definitive conclusions.

- The results of LFFA show that the distribution and parameter estimation method combination GIII-MAX was able to describe the majority of the 1-, 3-, 7-, 15-, and 30-day duration low flow samples, followed by the GIII-SOD. The number of GIII-MOM and LN3-MOM cases was found to be extremely small. The MAX method was found sensitive to small sample sizes and other undesirable features of some sample observations. Therefore, from a practical viewpoint, it is advisable to consider estimates from other distributions and parameter estimation methods. The outputs of LFFA were summarized both numerically by generating return values corresponding to selected return periods and graphically by generating extreme value plots for visual comparisons, which are useful for comprehending the behaviour of observed low flow extremes and theoretical distribution functions. However, deviations from these typical behaviours were not uncommon. Although the LFFA results for all active, discontinued, regulated and non-regulated (representative of natural or near natural flow conditions) stations are included in this report, the results for discontinued stations may not reflect current conditions due to potential environmental changes in the surrounding areas and human-driven anthropogenic influences that may have occurred overtime. Therefore, care must be exercised when interpreting results from such stations and also from stations with regulated flow regimes and stations located at the mouths of various lakes and water storage features. In particular, the regulated stations where pre-regulation natural or near natural flow regimes existed should be given careful attention. Although possible, separate analyses of low flows for pre- and post-regulation periods and their inter-comparisons were not conducted in this study due to scope limitations.
- As for the case of LFFA, the results of flow duration analyses are presented numerically in the form of summary tables on annual and monthly basis and graphically by plotting period of record flow duration curves for all stations. One summary table, listing flows corresponding to selected exceedance points for monthly and annual flow duration curves, and annual and monthly plots for every station were generated and included in the appendices of this report. Moreover, the low flow indices, summarized in various tables, corresponding to 90 and 95 percent exceedance points for both annual and monthly time scales can aid decision-making in many complex situations, arising due to short observational records and regulated flow regimes.

The information on low flow characteristics contained in this report is expected to help the MECP in fulfilling its provincial mandate and delivering superior service to industrial and domestic water users and wastewater dischargers in Ontario, in addition to supporting several environmental conservation projects across the province. Current estimates of low flow indices were derived from long-term observations and therefore reflect a more realistic picture of low flow conditions in Ontario streams.

4.2 Recommendations and Future Outlook

Based on LFFA results documented in this report and the developments that have taken place since the completion of the original low flow analysis study by Cumming Cockburn Limited (1990), the following recommendations are made to instigate future studies on characterizing low flow regimes in Ontario streams and advancing knowledge on low flow modelling and understanding of low flow occurrences from several applied perspectives.

- For testing serial correlations and temporal trends, this report utilized two different forms of the Spearman rank order correlation coefficient (Siegel, 1956). In the literature on hydrology, climatology and environmental sciences, as well as on copula-based multivariate analyses, Mann-Kendall test (Mann, 1945) is more commonly used. Although the power of these two tests have been found generally comparable (Yue et al., 2002), it would be useful to consider the Mann-Kendall test in order to offer the reader a different perspective on the results of nonparametric tests (e.g., Khaliq et al., 2009). It will also be useful to consider parametric tests for screening purposes because in situations where distribution related assumptions are satisfied the parametric tests can be more powerful than their nonparametric counterparts.
- Additional statistical distributions and parameter estimation methods for frequency analysis of low flows would be helpful in addressing the uncertainties related to the choice of a distribution function and selection of a parameter estimation method. This will help in producing relatively robust estimates of various return values, along with their expected uncertainty bands. It is important to note that significant amount of literature is available on the application of the L-moments approach of Hosking and Wallis (1997) for fitting distribution functions for low and high flow modelling. Therefore, in addition to other choices, this approach should also be evaluated in future studies for both at-site and regional frequency analysis of low flows in Ontario. Low flow estimation under both stationary and non-stationary conditions should also be given special consideration when selecting a distribution function and parameter estimation method.
- Studies on systematic selection and evaluation of statistical distributions for low flow characteristics based on hydrologic and/or climatologic homogeneous regions of Ontario are lacking. Therefore, it will be useful to investigate all potential candidate distributions following a systematic DSS, along the lines initiated by El Adlouni and Bobée (2018) for flood frequency analysis. It will also be useful to consider several goodness-of-fit tests, e.g.

Anderson-Darling (Anderson and Darling, 1952), likelihood ratio tests (e.g. Severini, 2000), Akaike information criterion (Akaike, 1974), and Bayesian information criterion (Schwarz, 1978).

- A parallel approach for modelling sequences of low flows and their characteristics utilizes the concept of flow deficit below a pre-determined threshold and then working with flow deficit events and performing joint frequency analyses (e.g. Liu et al., 2011; Masud et al., 2016). These approaches help characterise not only flow deficits in terms of the magnitude of deficit but also in terms of duration and intensity of the deficit (Tallaksen and van Lanen, 2004). It is believed that this framework provides rather a more complete picture of low flow characteristics of a stream. Although it is relatively difficult to incorporate an automated implementation of this procedure in a ready to use software due to determining several user- and site-dependent thresholds, an independent parallel offline analysis can be carried out depending upon available resources and technical expertise.
- To better characterise low flows from a physical viewpoint, it will be interesting to investigate and understand low flow generating mechanisms for each homogeneous region of Ontario or at the scale of large watersheds or other logical partitions of the province in addition to developing an overall understanding from seasonality perspectives along the lines initiated by Waylen and Woo (1987) and Burn et al. (2008). This helps to avoid mixing of low flow sequences generated from very different physical processes. Indirectly, this will mean performing LFFA separately for winter and summer seasonal low flows.
- Future studies should also consider addressing the influence of climate change on low flow return values following the guidelines proposed in Khaliq (2022) or adapting other credible approaches from the literature on hydrological implications of climate change. In addition to site-specific estimates, this can also be accomplished at the watershed or regional level. The regional level analyses can help generate relatively more robust and defensible signals of change at the larger scale. It should be kept in mind that such estimates are not easy to generate for watersheds that are affected by anthropogenic activities, such as water storage reservoirs and diversions.
- It will be worthwhile to compare outputs from single site frequency analyses and regional frequency analysis (RFA) approach. Among other reasons, the desire to have information on low flow indices at ungauged locations has led to the development of the RFA approach, which involves identification of a homogeneous region based on physical, hydrologic, climatic or statistical homogeneity concepts and then pooling information from the entire region following established procedures and thereby estimating magnitudes of desired low flow indices. The regional approach not only improves the quality of low flow estimates at sites with short records, but also provides a sound basis for the estimation of low flow indices at all ungauged locations within the target region of interest.
- For fitting statistical distributions to low flow sequences, the use of L-moments instead of conventional moments offers several advantages such as the possibility of characterizing a wider range of distributions, smaller bias and higher robustness of the estimators when

applied to short samples (see Hosking and Wallis, 1997). Future studies should explore L-moments as a reasonable alternative to the maximum likelihood approach, especially for short samples.

Appendices

This report accompanies five appendices A to E, which contain detailed results of data screening procedures, low flow analyses and analyses of flow durations. The arrangement of results into these appendices is explained below:

Appendix A: This appendix contains detailed results for the Northern Region.

Appendix B: This appendix contains detailed results for the Central Region.

Appendix C: This appendix contains detailed results for the Eastern region.

Appendix D: This appendix contains detailed results for the Southwestern region.

Appendix E: This appendix contains detailed results for the West Central region.

Appendix A

A4: Extreme Value Analysis at the Monthly Time Scale – Selected Return Values and Basic Statistics	A-197
A5: Extreme Value Plots of 7-Day Duration Low Flows for January to December Months. A-	281
A6: Analysis of Flow Durations – Flows Equalled or Exceeded Zero to 100% of the Time. A-	402
A7: Period of Record Annual Flow Duration Curves.....	A-939
A8: Period of Record Monthly Flow Duration Curves.....	A-1074

General Introduction

In this appendix, results of low flow analysis for the Northern Region are presented. This is one of the five administrative regions the province is divided into. The number of stations, with 5 or more years of recorded data, located in this region is 280 and that includes active, discontinued, regulated and non-regulated stations (see Figure A-1). For developing flow duration curves, 268 stations were used, while the rest (i.e. 02AB007, 02AB025, 02CC002, 02CF001, 02DC011, 02EA007, 02EA012, 02JC003, 04JA001, 04JC001, 05PD033, and 05PF051) were excluded due to less than 5 years of continuous daily flow data and missing values (see Table A-1). The period of record flow duration curves are termed annual flow duration curves and those corresponding to each of the 12 months are termed monthly flow duration curves in order to be consistent with previous analyses completed in 1990 by Cumming Cockburn Limited. The flows equalled or exceeded zero to 100% of the time, derived from annual and monthly flow duration curves, are listed in this appendix. Extreme value analyses were conducted separately for 1-, 3-, 7-, 15-, and 30-day duration annual low flow values. For this analysis, 240 stations were used and the rest were excluded due to less than 10 years of flow records. Those stations where less than 5 non-zero low flow values were available over 10 or more years of the record were also excluded. Detailed procedures for these analyses are described in the main report.

This appendix consists of seven different sections, which are explained below. In these sections, self-explanatory section captions are used and therefore table and figure numbers are not associated with all tables and figures.

A1: This section contains results of data screening procedures, concerning independence, trend and general randomness. In tables, the identifier NOT (SIG) means the test statistic was not significant (was significant) at the given significance level.

A2: This section contains results of extreme value analysis corresponding to 11 selected return periods, i.e. 1.005, 1.010, 1.111, 1.250, 2, 5, 10, 20, 50, 100, and 200 years. A separate table is included for each of the five considered low flow durations, i.e. 1-, 3-, 7-, 15-, and 30-day. In these tables, the most suitable distribution fitting procedure for the Gumbel III distribution (i.e. MAX-maximum likelihood, SOD-smallest observed drought and MOM-method of moments) or the method of moments for the three-parameter lognormal distribution (LN3), basic statistical characteristics (i.e. MEAN, SD-standard deviation, SKEW-coefficient of skewness, and CV-coefficient of variation) are also listed. In addition, the record length (REC) and the minimum value (MIN) of each low flow sample are also listed. For samples containing very small and/or zero flows, it was very likely to have negative return values for longer return periods (e.g. 100 or 200 years). These cases are shown using NA (i.e. not applicable), rather inserting zeros as was done in the previous report by Cumming Cockburn Limited. The MAX method for 1-day low flows at station 05PE010 did not produce sensible estimates and therefore the results for the SOD method are reported.

A3: This section contains extreme value plots for those stations where at least 10 years of continuous flow data was available. In these plots, negative return values for certain cases are not shown.

A4: This section contains results of extreme value analysis corresponding to 11 selected return periods, i.e. 1.005, 1.010, 1.111, 1.250, 2, 5, 10, 20, 50, 100, and 200 years, for 7-day duration low flows for each month of the year. Rest of the information is the same as in Section A2.

A5: This section contains extreme value plots for 7-day duration low flows for each month of the year. Rest of the information is the same as in Section A3.

A6: This section contains flow magnitudes that were equaled or exceeded zero to 100% of the time over the period of record for annual and monthly flow duration curves at 1% (PER) intervals. The period of record largest value is shown against 0 while the smallest value is shown against 100.

A7: This section contains annual flow duration curves for stations where at least 5 years of continuous data was available; see Table A-1 for the list of stations.

Figure A-1: Available HYDAT gauging stations for the Northern Region of Ontario.

Table A-1: The list of stations, with at least five years of continuous daily flow data, considered for the Northern Region of Ontario. A stands for Active; D for Discontinued; R for Regulated; and N for non-regulated. DA means ‘drainage area’ and PORU means ‘period of record used’.

A3: Extreme Value Plots for 1-, 3-, 7-, 15- and 30-Day Duration Annual Low Flows

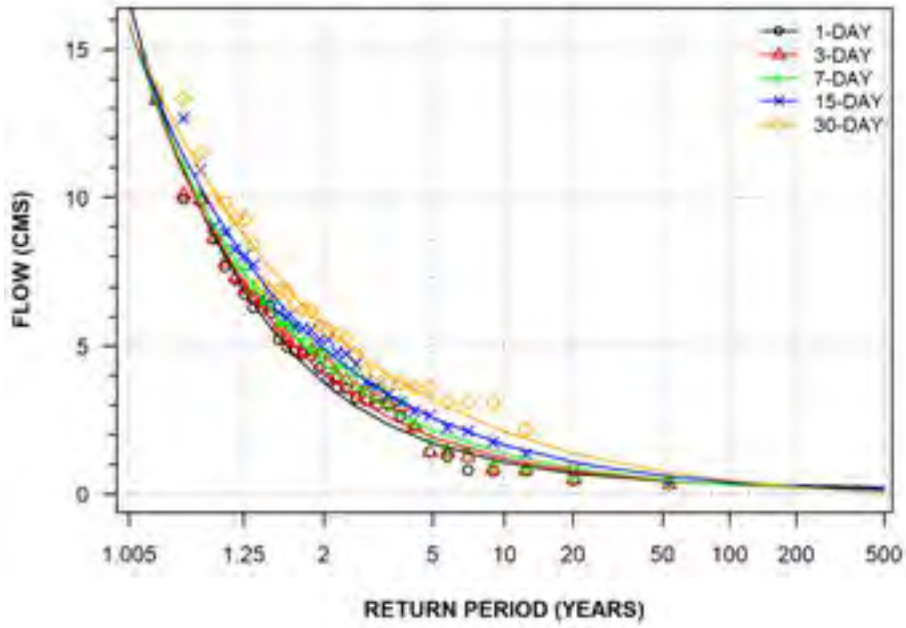

KAMINISTIQUIA RIVER NEAR DONA
(STATION NUMBER: 02AB001)

KAMINISTIQUIA RIVER AT OUTLET OF DOG LAKE
(STATION NUMBER: 02AB004)

SHEBANDOWAN RIVER AT GLENWATER
(STATION NUMBER: 02AB005)

KAMINISTQUIA RIVER AT KAMINISTQUIA
(STATION NUMBER: 02AB006)

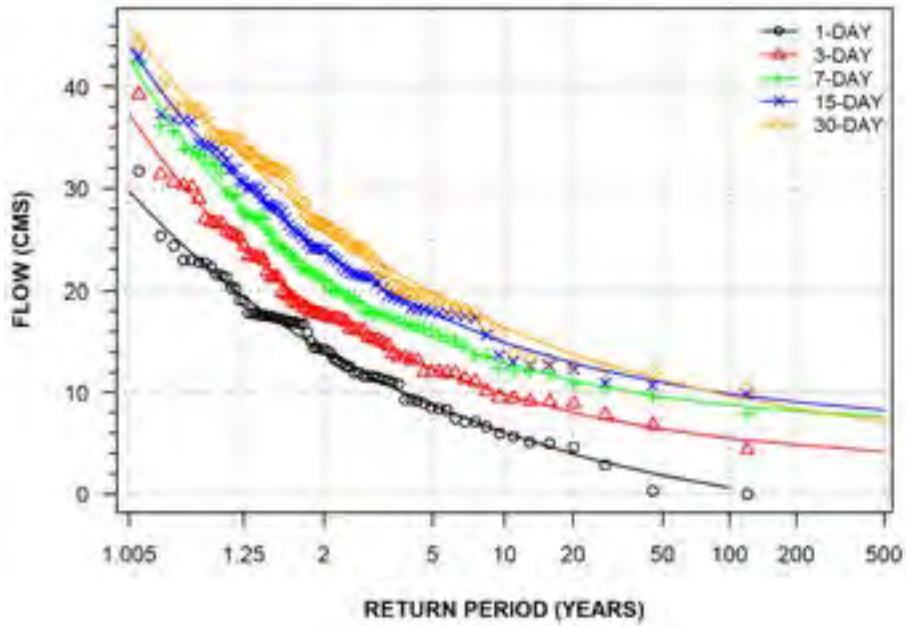

NEEBING RIVER NEAR THUNDER BAY
(STATION NUMBER: 02AB008)

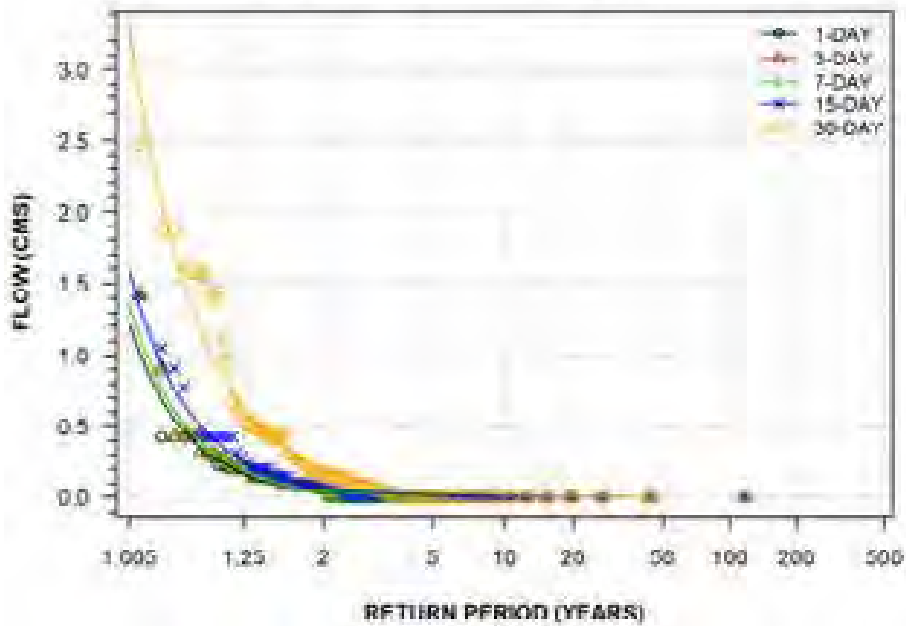

SHEBANDOWAN RIVER AT SUNSHINE
(STATION NUMBER: 02AB009)

**KAMINISTQUIA RIVER AT KAKABEKA FALLS POWERHOUSE
(STATION NUMBER: 02AB010)**

**SHEBANDOWAN RIVER AT OUTLET OF SHEBANDOWAN LAKE
(STATION NUMBER: 02AB011)**

KASHABOWIE RIVER AT OUTLET OF KASHABOWIE LAKE
(STATION NUMBER: 02AB013)

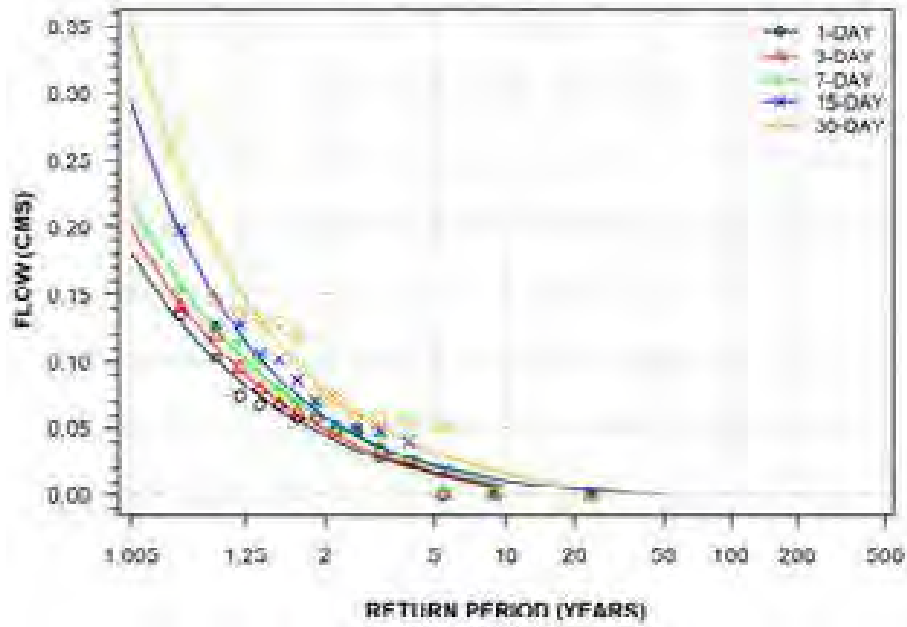

NORTH CURRENT RIVER NEAR THUNDER BAY
(STATION NUMBER: 02AB014)

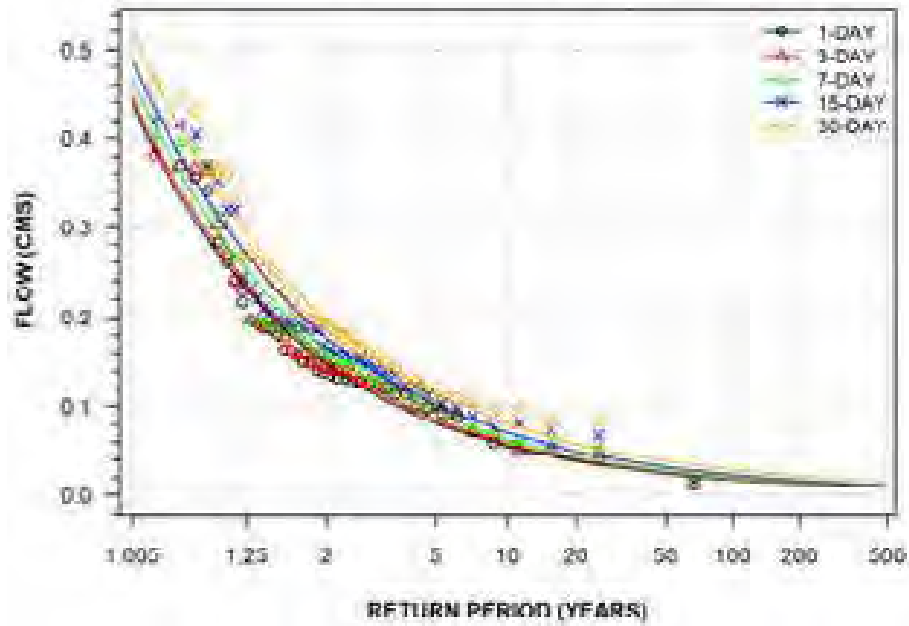

CURRENT RIVER NEAR STEPSTONE
(STATION NUMBER: 02AB015)

MCINTYRE RIVER AT THUNDER BAY
(STATION NUMBER: 02AB016)

WHITEFISH RIVER AT NOLALU
(STATION NUMBER: 02AB017)

MCVICAR CREEK AT THUNDER BAY
(STATION NUMBER: 02AB019)

MCINTYRE RIVER ABOVE THUNDER BAY
(STATION NUMBER: 02AB020)

CURRENT RIVER AT STEPSTONE
(STATION NUMBER: 02AB021)

**CORBETT CREEK NEAR MURILLO
(STATION NUMBER: 02AB022)**

**SLATE RIVER NEAR THUNDER BAY
(STATION NUMBER: 02AB023)**

NEEBING RIVER NEAR INTOLA
(STATION NUMBER: 02AB024)

WOLF RIVER AT HIGHWAY NO. 17
(STATION NUMBER: 02AC001)

BLACK STURGEON RIVER AT HIGHWAY NO. 17
(STATION NUMBER: 02AC002)

NIPIGON RIVER BELOW VIRGIN FALLS
(STATION NUMBER: 02AD006)

NIPIGON RIVER AT PINE PORTAGE
(STATION NUMBER: 02AD008)

OGOKI RIVER DIVERSION TO LAKE NIPIGON
(STATION NUMBER: 02AD009)

BLACKWATER RIVER AT BEARDMORE
(STATION NUMBER: 02AD010)

NIPIGON RIVER BELOW ALEXANDER GENERATING STATION
(STATION NUMBER: 02AD012)

GRAVEL RIVER NEAR CAVERS
(STATION NUMBER: 02AE001)

STEEL RIVER NEAR TERRACE BAY
(STATION NUMBER: 02BA002)

LITTLE PIC RIVER NEAR COLDWELL
(STATION NUMBER: 02BA003)

WHITESAND RIVER ABOVE SCHREIBER AT MINOVA MINE
(STATION NUMBER: 02BA005)

STEEL RIVER BELOW SANTOY LAKE
(STATION NUMBER: 02BA006)

BLACK RIVER NEAR MARATHON
(STATION NUMBER: 02BB002)

PIC RIVER NEAR MARATHON
(STATION NUMBER: 02BB003)

CEDAR CREEK NEAR HEMLO
(STATION NUMBER: 02BB004)

WHITE RIVER BELOW WHITE LAKE
(STATION NUMBER: 02BC004)

PUKASKWA RIVER AT PUKASKWA NATIONAL PARK
(STATION NUMBER: 02BC005)

**PUKASKWA RIVER BELOW FOX RIVER
(STATION NUMBER: 02BC006)**

**MAGPIE RIVER AT STEEP HILL FALLS
(STATION NUMBER: 02BD001)**

MICHIPICOTEN RIVER AT SCOTT FALLS
(STATION NUMBER: 02BD002)

MAGPIE RIVER NEAR MICHIPICOTEN
(STATION NUMBER: 02BD003)

WAWA CREEK AT WAWA
(STATION NUMBER: 02BD006)

MAGPIE RIVER NEAR WAWA
(STATION NUMBER: 02BD007)

MONTREAL RIVER NEAR MONTREAL RIVER HARBOUR
(STATION NUMBER: 02BE002)

BATCHAWANA RIVER NEAR BATCHAWANA
(STATION NUMBER: 02BF001)

A5: Extreme Value Plots of 7-Day Duration Low Flows for January to December Months

KAMINISTQUIA RIVER NEAR DONA
(STATION NUMBER: 02AB001; DURATION: 7-DAY)

KAMINISTQUIA RIVER AT OUTLET OF DOG LAKE
(STATION NUMBER: 02AB004; DURATION: 7-DAY)

SHEBANDOWAN RIVER AT GLENWATER
(STATION NUMBER: 02AB005; DURATION: 7-DAY)

KAMINISTQUIA RIVER AT KAMINISTQUIA
(STATION NUMBER: 02AB006; DURATION: 7-DAY)

NEEBING RIVER NEAR THUNDER BAY
(STATION NUMBER: 02AB008; DURATION: 7-DAY)

SHEBANDOWAN RIVER AT SUNSHINE
(STATION NUMBER: 02AB009; DURATION: 7-DAY)

KAMINISTQUIA RIVER AT KAKABEKA FALLS POWERHOUSE
(STATION NUMBER: 02AB010; DURATION: 7-DAY)

SHEBANDOWAN RIVER AT OUTLET OF SHEBANDOWAN LAKE
(STATION NUMBER: 02AB011; DURATION: 7-DAY)

KASHABOWIE RIVER AT OUTLET OF KASHABOWIE LAKE
(STATION NUMBER: 02AB013; DURATION: 7-DAY)

NORTH CURRENT RIVER NEAR THUNDER BAY
(STATION NUMBER: 02AB014; DURATION: 7-DAY)

CURRENT RIVER NEAR STEPSTONE
(STATION NUMBER: 02AB015; DURATION: 7-DAY)

MCINTYRE RIVER AT THUNDER BAY
(STATION NUMBER: 02AB018; DURATION: 7-DAY)

WHITEFISH RIVER AT NOLALU
(STATION NUMBER: 02AB017; DURATION: 7-DAY)

MCVICAR CREEK AT THUNDER BAY
(STATION NUMBER: 02AB019; DURATION: 7-DAY)

MCINTYRE RIVER ABOVE THUNDER BAY
(STATION NUMBER: 02AB020; DURATION: 7-DAY)

CURRENT RIVER AT STEPSTONE
(STATION NUMBER: 02AB021; DURATION: 7-DAY)

CORBETT CREEK NEAR MURILLO
 (STATION NUMBER: 02AB022; DURATION: 7-DAY)

SLATE RIVER NEAR THUNDER BAY
 (STATION NUMBER: 02AB023; DURATION: 7-DAY)

NEEBING RIVER NEAR INTOLA
(STATION NUMBER: 02AB024; DURATION: 7-DAY)

WOLF RIVER AT HIGHWAY NO. 17
(STATION NUMBER: 02AC001; DURATION: 7-DAY)

BLACK STURGEON RIVER AT HIGHWAY NO. 17
(STATION NUMBER: 02AC002; DURATION: 7-DAY)

NIPIGON RIVER BELOW VIRGIN FALLS
(STATION NUMBER: 02AD006; DURATION: 7-DAY)

NIPIGON RIVER AT PINE PORTAGE
(STATION NUMBER: 02AD009; DURATION: 7-DAY)

OGOKI RIVER DIVERSION TO LAKE NIPIGON
(STATION NUMBER: 02AD009; DURATION: 7-DAY)

BLACKWATER RIVER AT BEARDMORE
 (STATION NUMBER: 02AD010; DURATION: 7-DAY)

NIPIGON RIVER BELOW ALEXANDER GENERATING STATION
 (STATION NUMBER: 02AD012; DURATION: 7-DAY)

GRAVEL RIVER NEAR CAVERS
(STATION NUMBER: 02AE001; DURATION: 7-DAY)

STEEL RIVER NEAR TERRACE BAY
(STATION NUMBER: 02BA002; DURATION: 7-DAY)

LITTLE PIC RIVER NEAR COLDWELL
(STATION NUMBER: 02BA003; DURATION: 7-DAY)

WHITESAND RIVER ABOVE SCHREIBER AT MINOVA MINE
(STATION NUMBER: 02BA005; DURATION: 7-DAY)

STEEL RIVER BELOW SANTOY LAKE
(STATION NUMBER: 02BA006; DURATION: 7-DAY)

BLACK RIVER NEAR MARATHON
(STATION NUMBER: 02BB002; DURATION: 7-DAY)

PIC RIVER NEAR MARATHON
(STATION NUMBER: 02BB003; DURATION: 7-DAY)

CEDAR CREEK NEAR HEMLO
(STATION NUMBER: 02BB004; DURATION: 7-DAY)

WHITE RIVER BELOW WHITE LAKE
(STATION NUMBER: 02BC004; DURATION: 7-DAY)

PUKASKWA RIVER AT PUKASKWA NATIONAL PARK
(STATION NUMBER: 02BC005; DURATION: 7-DAY)

PUKASKWA RIVER BELOW FOX RIVER
(STATION NUMBER: 02BC006; DURATION: 7-DAY)

MAGPIE RIVER AT STEEP HILL FALLS
(STATION NUMBER: 02BD001; DURATION: 7-DAY)

MICHIPICOTEN RIVER AT SCOTT FALLS
(STATION NUMBER: 02BD002; DURATION: 7-DAY)

MAGPIE RIVER NEAR MICHIPICOTEN
(STATION NUMBER: 02BD003; DURATION: 7-DAY)

WAWA CREEK AT WAWA
 (STATION NUMBER: 02BD006; DURATION: 7-DAY)

MAGPIE RIVER NEAR WAWA
 (STATION NUMBER: 02BD007; DURATION: 7-DAY)

MONTREAL RIVER NEAR MONTREAL RIVER HARBOUR
(STATION NUMBER: 02BE002; DURATION: 7-DAY)

BATCHAWANA RIVER NEAR BATCHAWANA
(STATION NUMBER: 02BF001; DURATION: 7-DAY)

GOULAIS RIVER NEAR SEARCHMONT
(STATION NUMBER: 02BF002; DURATION: 7-DAY)

BIG CARP RIVER NEAR SAULT STE. MARIE
(STATION NUMBER: 02BF004; DURATION: 7-DAY)

NORBERG CREEK (SITE A) ABOVE BATCHAWANA RIVER
(STATION NUMBER: 02BF005; DURATION: 7-DAY)

NORBERG CREEK (SITE B) AT OUTLET OF TURKEY LAKE
