ABSTRACT

This report presents the raw data for the province of New Brunswick, for the period 1985-1988, from the Federal-Provincial Toxic Chemical Survey of Municipal Drinking Water Sources. All chemical analyses performed by the Water Quality Branch and Health and Welfare Canada are tabulated by municipality. Sections of the interpretive report have been included in this data summary so as to provide a narrative for the data and to ensure that the data for the province of New Brunswick is available in one document.

The Interpretive report provides a regional and resource management perspective.

SOMMAIRE

Sont présentées dans ce rapport les données brutes de 1985-1988 pour la province du Nouveau-Brunswick, obtenues lors de l'étude fédérale-provinciale sur les substances chimiques toxiques présentes dans les sources municipales d'eau potable.

Toutes les analyses chimiques, accomplies par la Branche de la qualité de l'eau et par Santé et Bien-être social Canada, sont compilées par municipalité. Des sections du Rapport interprétatif ont été incluses pour fins de narration et pour assurer que les données pour la province du Nouveau-Brunswick soient disponibles dans un document.

Le Rapport interprétatif présente une perspective régionale ainsi qu'une perspective pour les gestionnaires de ressources.

INTRODUCTION

The Federal-Provincial Toxic Chemical Survey of Municipal Drinking Water Sources was conceived as an intergovernmental and interdepartmental project to assess the quality of raw water entering municipal distribution systems in the Atlantic Region. Municipal withdrawal represents only one water use sector, but it is one that is of importance to all Canadians. The surface waters of Atlantic Canada are frequented by various aquatic and terrestrial life forms and provide recreational and aesthetic enjoyment. Water quantity and quality are of importance to the industrial/commercial sector also. It was however the environment-health linkage that this study addressed.

The Government of Canada, represented by Environment Canada (Water Quality Branch) and Health and Welfare Canada (Health Protection Branch), worked in close cooperation with the Department of Health and Community Services in New Brunswick, the Department of Health and Fitness in Nova Scotia, the Department of Environment and Lands in Newfoundland, and the Prince Edward Island Department of the Environment. Agriculture Canada was invited to participate as an information member of the working group. The goal of the study was to describe the current state of the raw drinking water sources serving Atlantic Canadian municipalities. In order to meet this objective, several needs/questions were identified:

1. The need to develop a database of water quality information for various surface and ground water sources of municipal drinking water.
2. The need to describe the water quality by means of a data comparison to the Guidelines for Canadian Drinking Water Quality (Health and Welfare Canada, 1987) with a focus in the areas of toxic organic and inorganic compounds.

3. The need to identify and investigate the relationship between water quality and anthropogenic activities including compounds potentially formed by some water treatment processes.
4. The need to investigate previously documented problem areas so as to determine their current status.
5. The need to identify existing acute problem areas, and respond to any specific situation in order to protect public health.
6. The need to identify emerging areas of concern based upon the data gathered.
7. The need to identify management strategies related to the water resource so as to protect or enhance the quality of water serving Atlantic Canadians.
8. The need to utilize the data and subsequent interpretation to plan future monitoring programs.

Two documents have been produced to meet these objectives. Interim data summary reports were generated for the periods 1985 to 1986 and 1987 (O'Neill and MacKeigan, 1987; MacKeigan, 1988). These reports met the federal commitment to this study by providing raw data and preliminary interpretations. A major interpretive report has been prepared which addresses questions 3 through 8. Due to the sheer amount of data available, the production of two volumes was warranted. This 1985-1988 data summary presents all the data obtained for the province of New Brunswick and serves as a companion volume to the interpretive report. This document collates all of the data so as to provide a useful reference document, for municipal, provincial and federal agencies interested in the water resource of New Brunswick.

COLLECTION PROCEDURES

Parameters and Sampling Sites

Over 150 chemicals were quantified on each supply source sampled during the survey. The parameter list was negotiated among the principal parties and represented a cross section of various in-use pesticides, past-use pesticides, synthetic organic chemicals, volatile organic materials (VOM), metals, major ions and physical parameters. Water from the distribution system was also collected for VOM analysis by Health and Welfare Canada. Parameter selections were based upon the Guidelines for Canadian Drinking Water Quality (Health and Welfare Canada, 1978) Water Quality Branch analytical capabilities, Health and Welfare Canada concerns, and the concerns of each individual province. A four year master suite of parameters was agreed upon. A detailed list of the chemicals investigated is presented in Table 1, including the parameter description, detection limit, the maximum acceptable concentrations (MAC) for drinking water and the CCREM (1987) aquatic limits. These represent the analyses performed by the Water Quality Branch. Health and Welfare Canada contracted Barringer-Magenta Ltd. of Toronto to conduct the analysis for volatile organic materials (VOM). A list of the VOMs quantified with minimum quantifiable limits and maximum allowable concentrations is presented in Table 2.

Sampling sites in New Brunswick were selected by the New Brunswick Department of Health. Ten municipalities were sampled in duplicate during a given year with sampling occurring during the spring and fall.

Sample Collection

Sampling was carried out in cooperation with representatives of the New Brunswick Department of Health and

frequently with personnel from the municipality. At each site sequential duplicate samples were obtained from the raw source. In the case of ground water sources, a tap in the pumphouse was generally used for sampling. Samples were taken prior to entry of the source water into any treatment system or the distribution network. Though water-infrastructure interaction could not be totally eliminated, it was minimized by flushing the tap. Duplicate volatile organic material samples were collected at both entry to the municipal system and at some point in the distribution network. In the case of surface waters, supply samples were collected from the stream or reservoir in close proximity to the system intake. The field procedures of Arseneault et al. (1984) were employed to maintain sample integrity.

Sample Preservation

Only specific bottles associated with trace organic chemical analyses were preserved in the field. VOM samples were always kept in a cooler on ice or in a refrigerator. Upon arrival in Moncton, they were repackaged with freezer packs and shipped by courier service to Barringer-Magenta. Samples for organochlorine insecticides, chlorobenzenes, polynuclear aromatic hydrocarbons and polychlorinated biphenyls were preserved in the field with the addition of pesticide grade hexane. Initially, carbamate insecticide samples were preserved by pH adjustment to pH 3 with 25% sulphuric acid. This practice was discontinued in 1988. Samples were kept as cool as possible during the sampling period.

The complexity of the analytical procedures employed reinforced the need to have a comprehensive quality assurance and quality control program in place during the course of the study.

QUALITY ASSURANCE/QUALITY CONTROL PROCEDURES

In order to ensure the validity of the generated data, a quality assurance/quality control (QA/QC) program was employed throughout. Each parameter group was represented within the QA/QC program, and addressed in an appropriate manner.

Firstly, all samples were collected in duplicate. In the case of metals, distilled water was obtained from the atomic absorption laboratory for the preparation of blanks to ensure the quality of the collection bottles.

Due to the complexity of the synthetic organic chemical analyses, it was necessary to have a more extensive quality assurance program. Laboratory glass distilled water was transported to the field for the purpose of preparing blanks and spiked blanks. In addition, natural waters collected from the sites were also spiked. Mixed spiking solutions were prepared by personnel of the organic laboratory and contained several compounds from each chemical group on the analytical parameter list. The contents of the spiking solutions were modified between 1985 and 1988 with some of the organochlorines, organophosphorus and chlorophenols being removed. Spiking solutions were kept refrigerated by the laboratory staff, and field personnel obtained sub-samples just prior to departure for sample collection. Once in the field, the solutions were kept cool and were only allowed to warm to ambient temperature at the time of use. A Hamilton^R syringe was used for spiking samples with 100 μ L of the appropriate spiking solution. The syringe was triple rinsed with solvent from a separate vial.

As part of the laboratory handling of the samples in the trace organic laboratory, method blanks were routinely incorporated into each extraction grouping to verify the integrity of the solvents, materials and glassware used in the analyses. Laboratory spikes of natural and distilled waters are

also utilized on a less frequent basis than the method blanks to provide an additional internal check on the extraction methodology. The atomic absorption laboratory utilizes National Bureau of Standards reference materials for internal laboratory quality control while the major ion and nutrient laboratory uses internal reference materials and ion balance checks to provide control charts. All quality control samples are handled in the same manner as any regular sample by both field and laboratory personnel.

Additionally, the Analytical Services Division routinely participates in intra-laboratory and inter-laboratory quality control studies and audits for inorganic and organic parameters, the results of which are tabulated by the Department.

Health and Welfare Canada established quality control guidelines for the contract analyses of volatile organic materials. No samples were quantified until daily blanks and standards had been verified, duplicates were analyzed if a target compound concentration lay outside the linear response of the instrumentation, and duplicates were routinely run on 10% of the samples. In addition field blanks and blind fortified samples were included during each sampling season. Barringer-Magenta were aware that the samples were quality controls but were not informed of the identity or concentration of the fortifying target compounds (LeBel, personal communication).

LABORATORY PROCEDURES

Upon receipt by the Analytical Services Division, the samples were immediately placed in large storage refrigerators, assigned laboratory control numbers, laboratory preserved when required, and initialized on the laboratory management system.

Most trace organic analyses were carried out employing methods highlighted in the NAQUADAT Dictionary of Parameter Codes 1985 (Environment Canada, 1985) and the Water Quality Branch Analytical Methods Manual 1979 (Environment Canada, 1979). Some methods were modified to complement the analytical instrumentation of the laboratory, and the nature of some of the soft and coloured waters encountered in the Atlantic Region.

The analysis of organochlorine insecticides, chlorobenzenes, and PCBs was carried out using simultaneous injection onto two capillary gas chromatography columns (electron capture detectors) with retention time, relative retention time, and relative peak response used for identification. Chlorophenols were extracted using in-situ acetylation (Stokker, 1987) and quantified with dual column capillary gas chromatography followed by electron capture detection.

Organophosphorus insecticides and carbofuran were quantified using packed column and capillary column gas chromatography with a thermionic nitrogen-phosphorus specific detector.

Polynuclear aromatic hydrocarbons were quantified using reverse phase high performance liquid chromatography with fluorescence detection at an excitation wavelength of 280 nm and emission wavelength of 370 nm.

Carbamates were determined using two different methods. In early 1985 the samples were quantified using a gas liquid chromatograph and a nitrogen-phosphorus detector. The remainder of 1985, 1986 and 1988, they were quantified using high performance liquid chromatography with post-column derivatization and fluorescence detection. This method uses a concentrator column that is installed in the sampler loop and is backflushed onto the analytical column. Separation is followed by post-column hydrolysis and the formation of a fluorophore prior to detection (Chaput, 1986).

Major ion and metal analyses were carried out using the methods in the Analytical Methods Manual (Environment Canada, 1979) or methods adapted for the region. Sulphate analyses were performed using both ion chromatography and colourimetric techniques. Chloride analyses changed from an ion specific electrode method to ion chromatography during the course of the study.

Barringer-Magenta, the contractor responsible for the VOM analyses used purge-and-trap gas chromatography mass spectrometer techniques. This method is best suited as a broad screening tool for the detection of an overall contamination problem (LeBel, personal communication), and includes the trihalomethanes which are formed in some water treatment processes that use chlorine as a disinfectant.

RESULTS

The purpose of this data summary is to present the observed data for the Province of New Brunswick in a manner that will facilitate subsequent distribution. This will be done in two steps. Firstly, the results section for the province of New Brunswick will be extracted from the Interpretive Report in order to provide a narrative description of the observations. For completeness, the discussion and recommendation sections for New Brunswick have also been extracted from the Interpretive Report. Secondly, the raw data for each municipal supply source will be tabulated in the appendices.

FIGURE 1: Drinking Water Sources Survey Sites in New Brunswick

Municipalities Sampled

Figure 1 presents the municipal raw sources that were sampled in the province of New Brunswick, while Table 3 gives the year of collection, location, whether the source is surface or ground water, an estimate of the population served, and a brief description of any treatment system in place at the time of sample collection.

- d New Brunswick Department of Health and Community Services, Personal Communication

SUPPLY SOURCE RESULTSInorganic Parameters

- Arsenic** Most observations were below the detection limit of 0.0005 mg/L. Detection limit values were reported in Fredericton at Wilmot #3 and #5 and at Sussex, Albert Street Well. Trace concentrations were detected in the spring of 1988 in St. Joseph, Newcastle, St. Leonard and Ste. Anne. No values were in excess of the Maximum Acceptable Concentration (MAC) of 0.05 mg/L in the Guidelines for Canadian Drinking Water Quality (Health and Welfare Canada, 1987).
- Cadmium** All observations were below the 0.001 mg/L detection limit and thus below the MAC of 0.005 mg/L.
- Chloride** All observations were below the MAC of 250 mg/L.
- Chromium** Chromium was not quantified in 1985. With the exception of some single detection limit values within a duplicate, most observations were less than the detection limit. Fredericton and Sussex reported detection limit values of 0.0002 mg/L in both duplicates. All of the 1988 sampling locations reported chromium at or slightly above the detection limit. These were still below the MAC of 0.05 mg/L.
- Copper** All copper values have been below the MAC of 1.0 mg/L.
- Fluoride** Sackville, Shediac, Chatham, St. Joseph, Newcastle, Tracadie, Caraquet, St. Leonard, Ste. Anne and the four Fredericton wells sampled displayed fluoride values that were an order of magnitude below the MAC of 1.5 mg/L.
- Iron** The Guidelines for Canadian Drinking Water Quality (Health and Welfare Canada, 1987) specify a guideline of 0.3 mg/L iron based principally upon aesthetic factors.

At concentrations above 0.3 mg/L iron may stain laundry or plumbing fixtures and may cause undesirable tastes in beverages (Health and Welfare Canada, 1978). Sackville, St. Stephen and Rothesay all displayed iron at or slightly above the 0.3 mg/L guideline. The raw water from St. Joseph contained 1.0 mg/L iron in the spring of 1988. This concentration however would be lowered by the treatment process that the town employs.

Sulphate All observations were below the 500 mg/L MAC.

Lead Most samples were less than the detection limit of 0.002 mg/L, although some samples were reported at the detection limit. The spring sample at Wilmot Well #5 in Fredericton was at the maximum acceptable concentration of 0.05 mg/L. The fall sample however was less than detection limit. With that noted exception, lead ranged from 0.01 mg/L to 0.035 mg/L all below the MAC. These observations are most likely due to infrastructure contamination from lead solder.

Manganese Seventeen raw sources were in excess of the 0.05 mg/L aesthetic objective. The highest manganese concentration reported was at St. Joseph, 2.0 mg/L while the second highest was Fredericton Wilmot Well #5 with spring and fall values of 1.4 and 1.3 mg/L respectively. Manganese guidelines are set principally upon aesthetic rationale as levels in excess of 0.05 mg/L stain plumbing fixtures and laundry and can cause undesirable tastes in beverages (Health and Welfare Canada, 1978). Treatment facilities at Fredericton and St. Joseph exist to lower the concentration of manganese in water delivered to households.

- Mercury** Almost all observations were less than the detection limit of 0.02 $\mu\text{g/L}$ and thus below the MAC of 1 $\mu\text{g/L}$. The St. Joseph supply was at the detection limit in the spring of 1988.
- Nitrate + Nitrite** A combined nitrate + nitrite-N value was reported. All observations were below the MAC of 10 mg/L for nitrate (as nitrogen). However, samples taken from agricultural areas (Sussex, Hartland, Grand Falls, and Drummond) had values in excess of 1.0 mg/L nitrate + nitrite-N. Drummond in the spring of 1988 had the highest observed nitrate + nitrite value, 9.0 mg/L of N, of any study site. Samples collected in the fall indicated that nitrate-Ns were present at a concentration of 1.2 mg/L. This is an indication that land-use activities may be affecting raw ground water quality.
- pH** The guideline for pH lies within a range of 6.5-8.5 pH units. Most observations were within this range with only a few single observations of 6.4 and 8.6.
- Zinc** The guideline for zinc is 5.0 mg/L. Most raw sources were below the detection limit of 0.01 mg/L. Sackville (surface source), Fredericton, St. Joseph, Newcastle, Eel River and Ste. Anne reported detection limit values for zinc. The guideline for zinc is set based upon aesthetics.
- Colour** Oromocto, Sackville and St. Jacques, (all surface sources) reported colour observations during one sampling period in excess of the aesthetic guideline. St. Joseph (a ground water source) was in excess of the guideline for both samplings.

Turbidity Most observations were below the 1987 MAC of 1 NTU. Five surface sources (Clair, Oromocto, Bathurst, Sackville and Moncton) were slightly above this concentration. However they were all below the 5 NTU aesthetic objective. A maximum of 5 NTU may be permitted if it can be demonstrated that disinfection is not compromised by the use of this less stringent value (Health and Welfare Canada, 1987). The ground water site at St. Joseph had mean turbidities of 8.0 and 8.3 in the spring and fall of 1988 respectively and warrants a follow up to ensure that these levels do not interfere with disinfection.

Organic and Pesticide Parameters

Seven organic chemical classes of environmental and health significance were included in the study parameter list. Within these classes only some parameters have Canadian Drinking Water Quality, or CCREM guidelines. These classes represent pesticides and industrial chemicals and encompass both past and present day usage.

Organophosphorus Compounds (OP)

These chemicals are phosphorus-containing pesticides used to protect plants from insect pests. Fifteen OP compounds were quantified during the course of this study. Single detection limit observations have been observed for phorate, carbophenothion and imidan. Similar observations have been noted for the other Atlantic Provinces. This implies that the aforementioned observations represent either contamination of materials or interfering coextractives. No OPs were consistently reported in any municipal raw water source.

Chlorinated Phenols (CP)

Chlorophenols have industrial applications as fungicides and algicides. Fourteen chlorophenol isomers were quantified; 2,4,6-trichlorophenol and 2,3,4,5-tetrachlorophenol were reported in the fall samples from Petit Rocher. As both samples were collected from a freshly painted well house that also housed chlorination reagents, it is possible that there may have been an interference from the building (O'Neill and MacKeigan, 1987). However both observations reported were below the MAC specified in the Guidelines for Canadian Drinking Water Quality (Health and Welfare Canada, 1987). No other chlorophenols were detected in any samples in New Brunswick.

Carbamates

Carbamates are nitrogen containing pesticides used in the protection of crops from insect pests. None of the five carbamates quantified was detected in any sample during 1985, 1986 or 1988. Carbamates were precluded from the 1987 analytical protocol due to instrument start up time (MacKeigan, 1988).

Organochlorine Compounds (OC)

These chlorine-containing insecticides are persistent and may bio-accumulate. Only a few are still registered for use in Canada. DDT, the most widely known and studied organochlorine, was banned in 1972. Seventeen organochlorine compounds were quantified during the study. In 1985 and 1986 only heptachlor and alpha-BHC were detected. In all cases observations were at the detection limit, and principally in surface waters. Alpha-BHC is a non-insecticidal isomer of lindane, which has a MAC of 0.004 mg/l. Alpha-BHC has been shown to be ubiquitous and has been reported in other raw surface

sources throughout the region. The reported concentrations of heptachlor were 3 orders of magnitude below the maximum acceptable concentration. No OC insecticides were detected during the 1987 or 1988 sampling.

**Polychlorinated
Biphenyls (PCB)**

These products were used as dielectric fluids, heat transfer fluids, flame retardants and water-proofing agents. They are persistent and have been banned from use in Canada. The detection limit for PCBs is 0.005 $\mu\text{g/L}$. No PCBs were detected in any municipal raw source during the study period.

**Chlorinated
Benzenes (CB)**

Chlorobenzenes have found uses both in industry and agriculture as pesticides, dyes, lubricants and solvents. Eleven chlorobenzene isomers were quantified at various specific detection limits based upon chlorine substitution. All quantified chlorobenzenes were below established detection limits for each specific isomer.

**Polynuclear Aromatic
Hydrocarbons (PAH)**

PAHs are produced from the incomplete combustion of organic matter in fuels and may also be produced through natural processes such as forest fires, volcanoes and tar pits (CCREM, 1987). These compounds are of interest due to their suspected carcinogenic nature. Fluoranthene is a low molecular weight PAH which is ubiquitous and has been reported in both surface waters and precipitation throughout the region. As a consequence several samples have had observations of fluoranthene in the range from the detection limit 0.001 $\mu\text{g/L}$ to 0.005 $\mu\text{g/L}$.

The Fredericton Cliff St. well had three other PAHs reported at detection limit in both the spring and fall samples. These observations warrant a follow up since no other municipal source surveyed in New Brunswick reported any of the six PAHs quantified other than fluoranthene.

Volatile Organic Materials (VOM) Health and Welfare Canada Analysis

Health and Welfare Canada, Health Protection Branch was responsible for the analysis of over 50 VOMs in both raw supply water and in samples collected at a distribution point in the supply network. These VOMs represent industrial/commercial solvents, thinners and degreasing agents, as well as some of the by-products of the chlorination of raw water sources.

Several VOMs were detected at concentrations between the MDL and MQL (MQL=10xMDL). Their presence is indicated as trace (T) in the data report with the estimated concentration shown in parenthesis.

The presence of some VOMs, i.e. dichloromethane, toluene, etc., at trace levels in blanks illustrates the ubiquity of these VOMs. Complete control of the whole analytical scheme is required to minimize these interferences.

Trihalomethanes

All raw and treated samples were under the 350 $\mu\text{g}/\text{L}$ HWC guidelines for THMs.

The THMs are usually present in treated water where chlorine is used as disinfectant. Approximately 50% of the sites sampled used chlorination in their treatment processes. The ranges of THM concentration in treated

water for each study year were:

1985 ND - 78 $\mu\text{g/L}$ (10 of 10 sites chlorinated)
1986 ND - 44 $\mu\text{g/L}$ (5 of 10 sites chlorinated)
1987 ND - 20 $\mu\text{g/L}$ (2 of 10 sites chlorinated)
1988 ND - 1.5 $\mu\text{g/L}$ (2 of 10 sites chlorinated)

Others

Tetrachloroethene was observed in the spring and fall, 1987 samples from the Albert Street well in Sussex. Concentrations ranged from 2.9 to 4.2 $\mu\text{g/L}$. These observations were subsequently addressed by the N.B. Department of Health and Community Services who conducted more analyses and confirmed the presence of tetrachloroethene. Provincial and municipal activities at this specific site are ongoing. Tetrachloroethene was also detected at 2.5 $\mu\text{g/L}$ in treated water from Shippegan in the fall of 1988.

In the spring of 1988 chloroethene (vinyl chloride) and dichloroethene were detected in the Ste. Anne de Madawaska raw water samples at 1.2 and 0.6 $\mu\text{g/L}$ respectively. These observations were also followed up by the provincial Department of Health and Community Services. The presence of these two compounds was not detected in the follow-up samples.

1,4-Dichlorobenzene was also detected in the treated water sample obtained from Tracadie. Concentrations observed were 0.6 $\mu\text{g/L}$ and 0.4 $\mu\text{g/L}$ in the spring and fall of 1988 respectively. These concentrations were less than the 5 $\mu\text{g/L}$ MAC of the Canadian Drinking Water Quality Guidelines (Health and Welfare Canada, 1987).

DISCUSSION

Based upon the parameters quantified during this study, the municipal raw sources sampled in New Brunswick for the most part have waters that meet the maximum acceptable concentrations of the Canadian Drinking Water Quality Guidelines (Health and Welfare Canada, 1987) while some failed to meet aesthetic guidelines. The presence of manganese, iron and colour, though not of major health concern, were in excess of the 1987 guidelines with manganese displaying the highest non-compliance frequency. This verifies past observations for New Brunswick (Eaton et al., 1986; Gillis and Walker, 1986). Manganese in the raw water from the Wilmot well field of Fredericton has been previously documented and a treatment facility using chlorination and filtration was brought on line in 1984 to lower manganese levels in treated water to meet the aesthetic objective of 0.05 mg/L (Viraraghavan et al., 1987).

Direct land use impact has traditionally been thought to affect individual private wells, especially those of the farm sector. However, data from municipal ground water supplies in agricultural areas indicate a concern for inputs of organics and inorganics to aquifers. Drummond, Grand Falls, Hartland and Sussex all had observations greater than 1.0 mg/L for nitrate + nitrite-N and all are within agricultural districts. Though the observed concentrations are within the maximum acceptable concentration, they do point to an area of concern. The Drummond well is of particular concern due to the high nitrate value (9 mg/L-N) observed in the spring of 1988.

The presence of tetrachloroethene (perchloroethene) in the spring and fall samples from one of the Sussex wells and in Shippegan, and vinyl chloride and dichloroethene in the spring of 1988 in the Ste. Anne raw supply point to another area of ground water concern: the contamination of ground waters by volatile organic materials. These man-made materials are

typically solvents, thinners, degreasing agents, drycleaning fluids and other chemicals of principally industrial/commercial use. The well known incident of perchloroethene in Fairvale, New Brunswick caused severe contamination and could only be remedied by hooking up the residences affected to a nearby municipal distribution system (Coon, 1987). As a result of the work carried out under this study and follow up by the New Brunswick Department of Health and Community Services, the Town of Sussex allocated capital to conduct a search and testing for a well to replace the Albert St. wells (Kings County Record, 1988). Though this study looked at only one well, the provincial follow-up investigated both Albert St. wells and the Magnolia Ave. well. The Magnolia Ave. well did not indicate perchloroethene presence.

Trihalomethanes were formed in most treated water samples where treatment included chlorine as a disinfectant. All concentrations were below the maximum acceptable concentration.

The surface water supplies of New Brunswick are subject to surface runoff and atmospheric deposition of contaminants as typified by the presence of alpha-BHC (a non-insecticidal isomer of lindane) in almost all surface sources. Alpha-BHC has been observed throughout the region in surface waters (O'Neill, 1988) and in precipitation (Brun, 1985). Though only in concentrations ranging from $0.001 \mu\text{g/L}$ to $0.005 \mu\text{g/L}$ (1-5 parts per trillion), the presence of alpha-BHC, combined with the low use of lindane regionally and evidence in the recent literature, illustrate the importance of atmospheric transport in the deposition of pollutants.

Ground water and surface water raw sources were observed to contain detection limit observations of the polynuclear aromatic hydrocarbon (PAH) fluoranthene. Fluoranthene, because of its relatively low molecular weight, is more closely associated with aqueous media as opposed to the other PAHs which are primarily

associated with sediments. The widespread presence of fluoranthene in surface waters points to atmospheric transport.

The presence of PAHs at detection limit values in the Fredericton Cliff Street well warrants follow-up even though the Fredericton distribution system has been modified since the well was sampled. Since the 1987 sampling in Fredericton, the north side of the community has been connected to the south side supply. Nevertheless if the Cliff Street well is maintained as a back-up or emergency supply, a follow-up is worthwhile.

In the spring of 1987, the set of samples from the Wilmot #5 well indicated the presence of lead at levels of 0.069 and 0.084 mg/L, above the MAC of 0.05 mg/L, while the fall samples were less than the MAC (0.003 and less than detection 0.002 mg/L). These observations bring to light the difficulty in obtaining a true unaltered water sample from ground water systems. Though the tap used to collect ground water is, in all cases, the one in closest proximity to the well, the interaction of the water and the infrastructure cannot be eliminated. It can only be minimized by flushing the tap several minutes prior to sample collection. This infrastructure interaction is most problematic with the metals due to their use in the piping, solder and tap construction.

Surface and ground water data were also compared to the CCREM (1987) guidelines for the protection of the aquatic environment. This comparison is valid for surface waters as they are frequented by aquatic and terrestrial life forms. To a limited extent this is also applicable to ground water, in that ground water usually contributes to streamflow. Metal observations were below the guidelines for aquatic life as were the organics and pesticides. Organochlorines for example are generally associated with the sediment component of the water column and as such are not generally observed in waters at detectable concentrations. However, field investigations over

several years have indicated the presence of DDT metabolites in fish liver tissue even though water concentrations have been less than detection (Lockerbie and Clair, 1988).

The pH at one surface water site was below the 6.5 guideline. The inputs of acidic precipitation from both localized and long range sources have been documented in the Region (Howell and Brooksbank, 1987) as have the impacts upon various aquatic life forms, especially the Atlantic salmon (Watt, 1987).

Data from this study have illustrated natural occurrences such as the presence of manganese, the influence of land use activities through observed concentrations of nitrates and industrial compounds, and a combination of both where nature transports man-made pollutants and deposits them in precipitation.

RECOMMENDATIONS

In the province of New Brunswick, with its mixed supply sources, a full range of natural and anthropogenic inputs may be affecting observed water quality. A municipal ground water source inventory is not necessary since one already exists (Hydra, 1988). This inventory provides a risk assessment for 145 municipal wells and is discussed further in Section 5.4. This document, though produced in conjunction with the N.B. Department of Municipal Affairs and Environment, would be useful to the N.B. Department of Health and Community Services as a reference document to help identify potential contamination sources.

The Federal-Provincial Drinking Water Sources Toxic Chemical Survey was conceived as a broad data gathering and interpretation process. The area of ground water pollution and protection would appear to be the emerging area of concern. Even though water quality presently meets most Guidelines for Canadian Drinking Water Quality (1987) criteria, there are some instances where aesthetic guidelines are not met. The effects of land use seem quite clear in the case of Drummond Well #2, where the well is in a depression adjacent to a fertilizer plant in an agricultural district. The levels of nitrate reported in the spring of 1988 at Drummond (9 mg/L-N) are just below the MAC of 10 mg/L and are therefore of concern.

The drinking water sources survey should be continued with a narrower focus and targetting specific problem sources, in-use pesticides, or volatile organic materials.

ACKNOWLEDGEMENTS

An undertaking of this size would not have been possible without the cooperation of the various health inspectors, and municipal water departments who provided access to the raw sources for sample collection.

The personnel of the Water Quality Branch, Atlantic Region, Analytical Services Division, Organic and Inorganic Sections must be acknowledged for their significant contribution to this project. The personnel of the Water Quality Branch, Electronic Data Processing Section must also be thanked for their assistance in data manipulation and retrieval.

Mrs. Louise Boulter must be thanked for her patience in typing the manuscript.

APPENDIX I

Quality Assurance/Quality Control Results

The intent of the Quality Assurance/Quality Control component was to monitor the entire survey encompassing field techniques with respect to sample collection, preservation, handling and transport, as well as analytical procedures, laboratory data entry and reporting. The major portion of QA/QC fell into the area of spiked samples and spiked distilled water. The use of spiked media was critical in measuring field preservation and analytical quantification techniques.

There were several factors that had to be considered when interpreting the resultant QA/QC data. Early in each sampling year a new spiking solution was prepared by Analytical Services Division personnel for use during that season's sampling. This solution could have been prepared by any one of four individuals. Thus there would be inherent minor differences due to the individual laboratory techniques of each person. Additionally, the quality of any individual neat or stock standard could influence the quality of the final spike prepared. Spikes were prepared so that the concentration of a constituent would be approximately 10 times its detection limit. This was also near the concentration of the injection standard thus providing a check on the standard solutions.

Spiking would have been carried out in the field by any one of three Water Quality Branch personnel and one non-WQB individual using up to three different syringe sizes (100, 250, 500 μ L). Though 100 μ L was the predetermined volume of spiking solution added, individual syringe technique variances would have applied, coupled with the tolerances of a specific syringe size.

Lastly the analytical conditions were established on a broad scan basis. For example, in the quantification of the organochlorines, the optimal conditions were established for a scan of 17 chemicals and PCBs rather than for a single constituent of the group.

Thus the QA/QC data must be viewed from two aspects: on a yearly basis to indicate the bias of the four spiking solutions, and on a provincial basis to examine variances as a result of individual spiking and matrix effects. In order to describe any variances, the minimum, maximum, mean and median percent recoveries were calculated as well as the standard deviation. The purpose of yearly and provincial analyses of recovery data was to try to identify whether problem areas existed and if they did, how they might be remedied. As all QA/QC samples were intended as process samples, the identification of errors can only be elementary. Chau et al. (1986) have used a standard deviation of 25% as a guideline in evaluating analytical performance of private sector contract laboratories. This same value was employed in this interpretation.

Yearly Basis

As spiking solutions were freshly prepared at the start of each sampling season, it is most important to first view each spiking solution as a separate entity.

Organochlorines Eighteen OCs were on the initial spiking list. This was eventually modified such that by 1987 only 11 OCs were in the spike. The 1985 data indicate a high bias as several median recoveries were greater than 100%. However, in all cases, relative standard deviations were lowered during the period 1985 to 1988 indicating an improved performance for this group.

- Chlorobenzenes Performance was generally good with respect to chlorobenzene analyses. Standard deviations were stable and slightly improved over the course of the survey. There were two instances of sample evaporation in 1988 that resulted in poor recovery thus skewing the standard deviation.
- PAH Performance generally improved from 1985 to 1988. The relative standard deviation (RSD) for fluoranthene was lowered from 31.4% in 1985 to 8.6% in the spring of 1988.
- Chlorophenols Chlorophenol performance was stable during the four year survey. Two samples that evaporated raised the RSD in 1988 but when recalculated without these two known errors the RSDs are similar to 1985-1987.
- Carbamates Carbaryl was the only carbamate on the QA/QC program in 1985 while aldicarb and its two metabolites were added in 1986. No 1987 data are available due to instrument start up time. The RSDs are acceptable for aldicarb and its metabolites.
- Organophosphorus Only azinphosmethyl, disyston, malathion and phorate were on the QA/QC protocol all 4 years although almost all OPs were spiked in 1985. Several samples indicated very low recoveries while others from the same period were satisfactory. As the OPs are generally less stable than the other groups quantified, it was expected that there would be wider variances in the recoveries.

In general, for a specific parameter, relative standard deviations remained stable or decreased from 1985-1988 indicating consistent or improving performance respectively. Without question the OP group were problematic with a wider range of percent recoveries and RSDs.

Table 4 presents a group summary and the number of flagged results that exceeded the 25% variance of Chau et al. (1986). The first part of the table presents the data in their raw form while the second part of the table illustrates the results when documented field or laboratory errors are accounted for. As can be seen, in 1985 the organochlorine group (OC) was the most problematic with 14 flagged spikes. The high relative standard deviation appears to be due to an incidence of double spiking in the field but this could not be confirmed from field notes and, as such must be accepted into the data set. The edited data indicate that in 1985, 42% of the spiked constituents were in excess of the 25% relative standard deviation limit and that by 1987 and 1988 this had lowered to 9% and 12% respectively. On a yearly interpretation this would indicate that overall performance improved from 1985 to 1988.

Provincial Basis

Spiking in the field was carried out at the time of sampling by the individual collecting the samples. In New Brunswick up to three WQB personnel carried out this function while in Nova Scotia and PEI one WQB person prepared the spikes. In Newfoundland non-WQB personnel collected samples and prepared the spikes. For the purposes of this data analysis, it was assumed that any biases inherent in a spiking solution would be manifested in each province and that laboratory procedures would be consistent from year to year.

Table 5 summarizes the parameter groups and flags on a provincial basis. A review of each chemical group indicated that where one WQB person was responsible for the spiking, the standard deviations were lower. This was the case for Prince Edward Island and Nova Scotia. It should be mentioned though that on PEI only ground water was spiked and PEI was included only from 1986 onward. Thus the high bias of the 1985 spikes did not reflect in the total number of flags. Where ground water does not generally contain the amounts of organic materials and suspended sediments that does surface water, the lower RSDs may be due to reduced matrix effects. The number of flags from Nova Scotia and New Brunswick are lower than those from Newfoundland indicating that transport time from Newfoundland may also have caused some differences. Table 5 does serve to indicate that the fewer the individuals spiking samples, and the shorter the transport time, the fewer flags reported.

WQB data are consistent with the work of Benoit and LeBel (1986) in that the results for OC, PAH and CB illustrate less variance than OP analyses. Another complicating factor is that up to 9 individuals in the laboratory could have handled the samples during extraction. This factor cannot be delineated and must be left under the area of good laboratory practices. Laboratory quantification was generally carried out by the same individual per parameter group thus minimizing random interpretation errors.

The QA/QC data indicate the quality of study data as reflected from the point of sample collection to result reporting. A differentiation of field versus laboratory performance cannot be undertaken due to the nature of the data.

"1,2,4-trichlorobenzene"	C6H3Cl3	55	1.0	0.5		(d)	750 (c)	
Miscellaneous	2-chloroethyl vinyl ether	(C2H4Cl)(C2H3)O	56	2.0				
	acrolein (2-propenal)	CH2CHCHO	57	25.0	10.0			
	acrylonitrile (vinyl cyanide)	CH2CHCN	58	10.0	5.0			
	dichloroacetonitrile	CHCl2CN	59	15.0	5.0			
	"1,4-dioxane"	C4H8O2	** 60	500.0				
	hexachlorobutadiene (HCBD)	C4Cl6	61	1.0	0.5			
	carbon disulfide	CS2	** 62	5.0				

** - deleted for 1987 study

a - MAC = maximum acceptable concentration

b - MCL = maximum contaminant level (enforceable)

c - RMCL recommended contaminant level (non-enforceable)

d - no health guideline; odor threshold d = 0.1-10 ug/L

* - new compound for 1987 study
