ENVIRONMENTAL PROTECTION SERVICE REPORT SERIES

Surveillance reports present the results of monitoring programs carried out by the Environmental Protection Service. These reports will usually be published on a regular basis.

Other categories in the EPS series include such groups as Regulations, Codes and Protocols, Policy and Planning, Technical Appraisal, Technology Development, Surveillance, and Reprints of Published Papers.

Inquiries pertaining to Environmental Protection Service Reports should be directed to the Environmental Protection Service, Department of the Environment, Ottawa K1A 0H3, Ontario, Canada.

ABSTRACT

A bacteriological and sanitary assessment study of the Cocagne River Estuary, a part of New Brunswick Shellfish Area #6, was conducted during May and June, 1972 by personnel of the Mobile Bacteriological Laboratory Unit of Environmental Protection Service, Atlantic Region.

The purpose of the study was to assess the adequacy of the present closure (SOR/71-28 New Brunswick Fishery Regulations para 6-5) as a result of a request from local fishermen in the area. The closure reads: "Cocagne Harbour and Cocagne River, Kent County westerly of a straight line drawn across the harbour from Oyster Survey Monument No. K-16 on Jim Long's Cape as shown on the plan showing oyster leases in Cocagne Harbour to Oyster Survey Monument K-21".

The existing closure was found to be adequate and in compliance with national standards for shellfish producing waters.

1. INTRODUCTION

A bacteriological and sanitary assessment of the Cocagne River Estuary, New Brunswick (N.B. Shellfish Area #6), was conducted during May and June, 1972 by personnel of the Mobile Bacteriological Laboratory Unit of Environmental Protection Service, Atlantic Region.

The purpose of the study was to assess the need or the adequacy of the present closure (SOR/71-28 New Brunswick Fishery Regulations para 6-5) as a result of a request from local fishermen in the area. The closure area has an abundance of shellfish and therefore, it has economic importance.

The Cocagne River and Harbour receives sanitary sewage from numerous outfalls along both sides of the estuary. A 1968 bacteriological and sanitary survey by Public Health Engineering Division, Atlantic Region (Silliphant, et al. MS, 1968) showed that the Cocagne River and Harbour were grossly polluted.

2. METHODS

All samples were tested for coliform bacteria by the methods outlined in A.P.H.A. "Recommended Procedures for the Bacteriological Examination of Sea Water and Shellfish" Fourth Edition, 1970. Coliform and fecal coliform densities were determined from all samples by multiple dilution tubes (MPN) methods using Bacto-Lauryl Tryptose Broth with three or five tubes in each of at least three consecutive decimal dilutions with incubation at 35.5°C for 24 and 48 hours. Confirmation

of all positive cultures was completed in: (a) Bacto-Brilliant Green Bile Broth with incubation at 35.5°C for 24 and 48 hours, and in (b) Bacto-E.C. medium with incubation for 24 hours at 44.5°C in a recirculating water bath.

Salinity determinations were made by the Knudsen Method from composite samples. Salinities were expressed as parts per thousand (See Table 1).

Samples were obtained from 50 sampling stations with the aid of a rod sampling device. These samples were placed into sterile 8-ounce glass bottles and transported to the Mobile Laboratory within 1 hour of collection. The samples were immediately inoculated into prepared fermentation tubes, using the appropriate graduated quantities, for incubation.

3. RESULTS

The locations of the 50 water sampling stations used during this study are shown in Figure 1. Bacteriological results for the 189 water samples collected from these stations are recorded in Table 2. Water temperature, air temperature, tidal stage and wind data, as well as daily rainfall data (Atmospheric Environment Service, Department of the Environment) for Cocagne River, N.B., are presented in Tables 3, 4 and 5, respectively.

There were twenty-eight stations (56 per cent) with median coliform MPN counts greater than 70, and fifteen stations (30 per cent)

where the median coliform MPN counts exceeded 230. Twenty-two stations (44 per cent) had median fecal coliform MPN counts greater than 23.

The Cocagne River, upstream of the bridge crossing Route 11 highway, receives sanitary wastes from approximately 15 single family dwellings or cottages located on the south side of the river. This occurs either as a direct discharge or a septic tank effluent. In the immediate bridge area, three restaurants, one service station, and several homes discharge sanitary wastes. Refuse from the restaurants is stored on the bank of the river and presents a danger of spilling into the river before proper disposal.

In the harbour area, sanitary wastes from E.P. Melanson's Lobster Packing Plant are discharged, untreated, directly into the harbour. This plant has several process water outfalls; however, these are relatively free of any obvious process waste material. Several storm drains also empty into the harbour. In the wharf area, where most outfalls empty, there was evidence of oil or gas on the water. This could be lubricating oil or gas from the truck-fleet servicing operations.

Other minor sources of pollution in the watershed, such as drainage from manure piles or other general farming activities, cause noticeable effects on coliform densities in the Cocagne River. This was indicated following the heavy rainfall on June 1. The coliform densities in the upper reaches of the river increased significantly at this time.

4. DISCUSSION

It is apparent from the results of the sanitary investigation that numerous sources of untreated waste enter the Cocagne estuary area. The effects of these discharges on the receiving-water quality is substantiated by the bacteriological results. The effect of rainfall is particularly apparent in these results. On June 1 and 2, precipitation amounted to 0.61 and 0.55 inches, respectively. Bacteriological results of samples obtained on June 2, showed coliform MPN values in excess of 1,100 at stations #1 to #16 with only one exception at station #9. Rainfall-induced landwash has a significant effect on the bacteriological contamination of this estuary.

5. CONCLUSIONS

It may be concluded that:

- (a) the need for continued maintenance of the existing shellfish closure, is confirmed by the bacteriological data, and the number of sewer outfalls noted by this report.

6. RECOMMENDATIONS

It is recommended that:

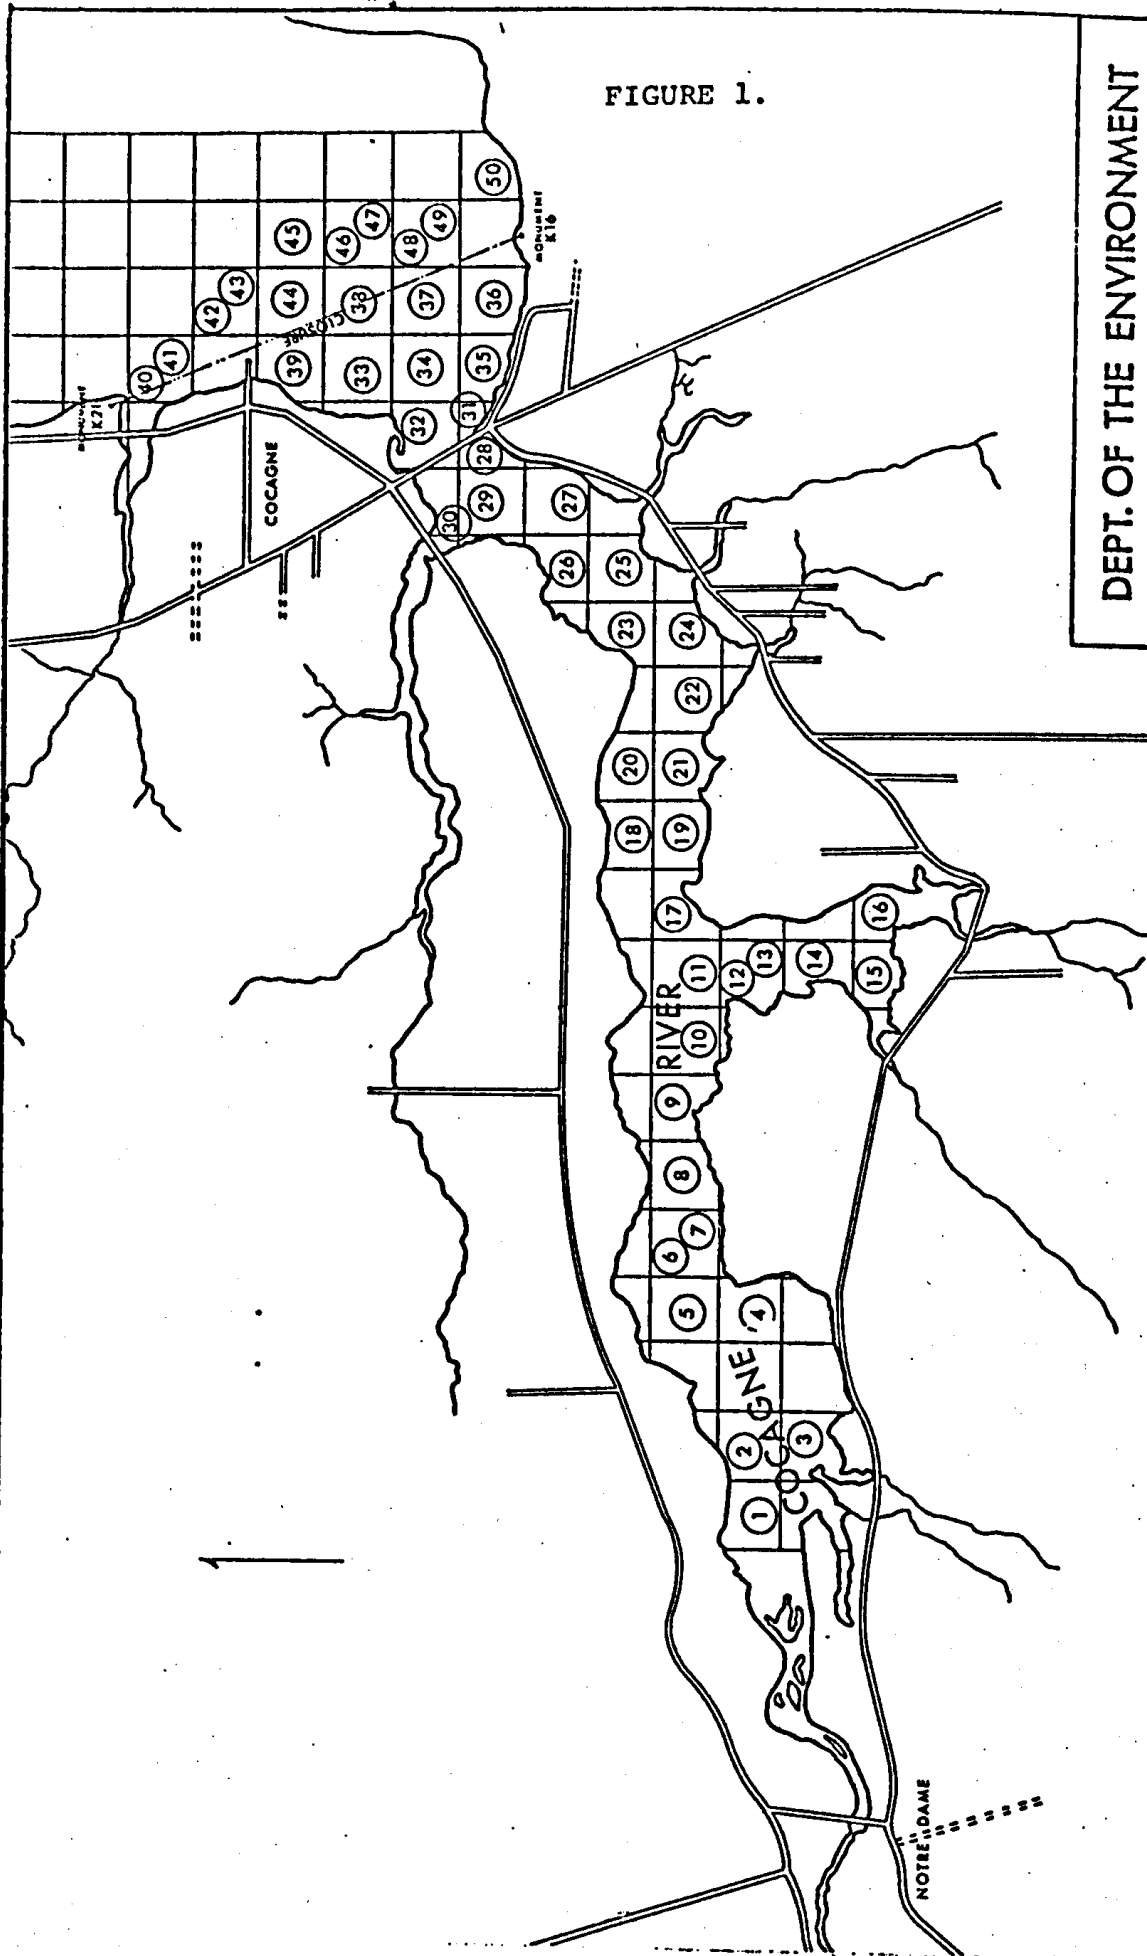

- (a) the existing shellfish closure on the Cocagne River and Harbour, Kent County, N.B. as defined

by the New Brunswick Fishery Regulations P.C.

1971-16, January 12, 1971, Schedule 'E: Item 6-5,
is adequate and should remain in effect.

- (b) the Environmental Protection Service should inform the appropriate pollution abatement authorities of the pollution condition in the Cocagne River and Estuary waters.
