RECOMMENDATIONS REGARDING THE SPECIAL AGREEMENT ON THE RAPESEED INDUSTRY BETWEEN DREE AND THE GOVERNMENTS OF THE PRAIRIE PROVINCES

Canada. Dept of Rigional Economic Expansion
DET. OF REGIONAL ECONOMIC CE

ON THE RAPESEED INDUSTRY BETWEEN DREE AND THE GOVERNMENTS OF THE THREE PRAIRIE PROVINCES

BIBLIOTHEQUE EXPANSION L'CONOMIQUE

### ADDITIONAL CRUSHERS

It is recommended that DREE be prepared to support the establishment of up to three additional rapeseed crushers in the Prairie region subject to the following criteria.

- That the prospective owners of such crushers provide adequate assurance that the bulk of their oil sales will be in overseas markets.
- 2. That any such crushers be located in districts which offer adequate access to supplies of raw rapeseed and that the particular site chosen be well situated with respect to a plentiful supply of water as well as providing good highway and rail access. The Peace River district in Alberta has two or three specific sites which are suitable. In northwestern Saskatchewan North Battleford is the superior location. In eastern Saskatchewan western Manitoba the Yorkton-Roblin district, while inferior to the other locations identified, could support a third plant.
- 3. That any crushers receiving financial support be of adequate size to realize the economies of large scale production.

  This would require a crushing capacity and associated supporting equipment sufficient to process a minimum of 600 tons of rapeseed per day. Each 600 ton facility would require a capital expenditure of 5.5-6.5 million dollars and would employ approximately 60-70 persons.

29.9 R2 TO INSURE THE SUCCESSFUL COMPETITIVE OPERATION OF ANY NEW PLANTS CON-STRUCTED AND TO ENHANCE THE VIABILITY OF THE EXISTING INDUSTRY IN THE PRAIRIE REGION IT IS FURTHER RECOMMENDED

#### RESEARCH FACILITIES

- 1. That the plant breeding research program being conducted by the Canada Department of Agriculture on the University of Saskatchewan campus in Saskatoon be accelerated. DREE's role in this effort should be to urge the Canada Department of Agriculture to assign a higher priority to the acquisition of a growth chamber and the employment of additional support staff. Selective commitment of DREE funds could also be considered. Total cost of accelerating this phase of the research effort would be 1-1.5 million dollars.
- 2. That the CDA research station in Saskatoon be provided a small scale (i.e. 500 pound capacity) pilot crushing facility. DREE's role should again be to urge the federal Department of Industry, Trade and Commerce and industry representatives to come to a speedy agreement regarding such differences as exist regarding size of facility and financial arrangements. Again selective commitment of DREE funds could be considered.
- 3. That existing research efforts into the end uses of rapeseed derivatives be transferred to the University of Saskatchewan campus in Saskatoon in order to insure the maximum complementarity of research effort from plant breeding to finished product. Consideration should be given to combining the

research effort on rapeseed derivatives with a research complex for proteins, oils, and starches. Once more DREE's role in this regard would be one of coordinating the various groups interested in the creation of such a complex and the possible selective commitment of funds. Total costs of a crusher through protein-oil-starch research complex (2 and 3 above combined) have been (roughly) estimated at 4-6 million dollars.

### HANDLING, TRANSPORTATION, AND STORAGE

- 4. The Canadian Wheat Board's quota system should be altered in a manner which would insure the crushers access to an adequate supply of raw rapeseed with the minimum possible assembly cost regardless of fluctuations in the total demand for raw rapeseed.

  DREE should make representation to the Wheat Board to this effect.
- 5. The rate structure under which rapeseed and its derivatives move needs to be altered.
  - a) Rapeseed moves to overseas and eastern Canadian crushers at Crows Nest Pass rates whereas Prairie crushers must pay domestic commodity rates to assemble their raw rapeseed by rail.
  - more valuable derivatives move at higher domestic commodity rates (or agreed rates) to domestic markets and under somewhat lower export rates to overseas markets. The combination of (a) and (b) puts Prairie locations at an artificial disadvantage with respect to eastern Canadian crushers. The

rate structure should be modified so that the Crows Nest
Pass rates apply only on movement of raw rapeseed to

export markets and not between any two points in Canada.

DREE should make representation to this effect to the
Canadian Transport Commission.

6. Oil and feed storage failities in Vancouver are inadequate to support the large scale export of either product. Conceptually it would seem to be a simple matter to expand these facilities. Representation to the National Harbours Board or an incentive grant to the individual companies should be considered. No cost estimates have been made.

# WESTERN CANADIAN RAPESEED INDUSTRY SUPPLEMENT - JULY 1973

This supplement was prepared with the objective of bringing up to date the material presented in the original report of the same title which was prepared in February 1973.

The protein feed shortage which was evident earlier this year has intensified to the point where there is now concern over whether all potential buyers can be accommodated. This has led to an embargo on the export of soybeans from the United States and on both soybean and rapeseed from Canada. At the same time the demand for rapeseed oil remains strong domestically and is growing internationally. In the immediate future, then, there will certainly be no problem of disposing of raw rapeseed. How long this situation will last will not likely be clear at least until this year's crops are in. The extreme shortage is almost certainly of a "temporary" nature, however, and decisions taken regarding the extent to which the western rapeseed industry should be encouraged should look beyond the present.

Looking to the next several years the prospects for the western Canadian rapeseed industry appear favorable especially if selective encouragement and selective corrective action is taken in the near future.

In looking at the industry as a whole it now seems reasonable to classify the problems facing it in the following manner. The first has to do with improving the viability and competitiveness of the existing industry. Problems here are those associated with product improvement as well as those associated with transportation. Second is the question of whether or not sufficient demand exists to warrant an expansion of the industry. Of interest here is the rate at which both foreign and domestic demand is expanding and whether or not domestic producers, crushers, and refiners are capable of meeting this demand. Each of these points is considered separately below.

### VIABILITY OF THE EXISTING INDUSTRY

As outlined in the initial paper, rapeseed and its derivatives compete in the product market with a number of alternative sources of vegetable oil and protein. Within the region rapeseed competes with wheat and other grains for resource inputs. In both input and product markets rapeseed has made impressive gains during the past decade.

Because plant breeding and research in product improvement is at an adolescent stage, significant additional improvements are possible which will strengthen the competitiveness of rapeseed both in product markets and for resource inputs. The points at which an accelerated research effort promises early gains are identified with the letter R on Figure 1.

R<sub>1</sub> Improvement in yield and reduction of time required for plant to reach maturity. Yield has gone up by 40 percent in the past 25 years and there has been no falling off in percentage gain in the latest experiments. This implies that the yield plateau is something well in excess of what is currently being experienced. Soybean yield on the other hand has been relatively stable for some years now. Length

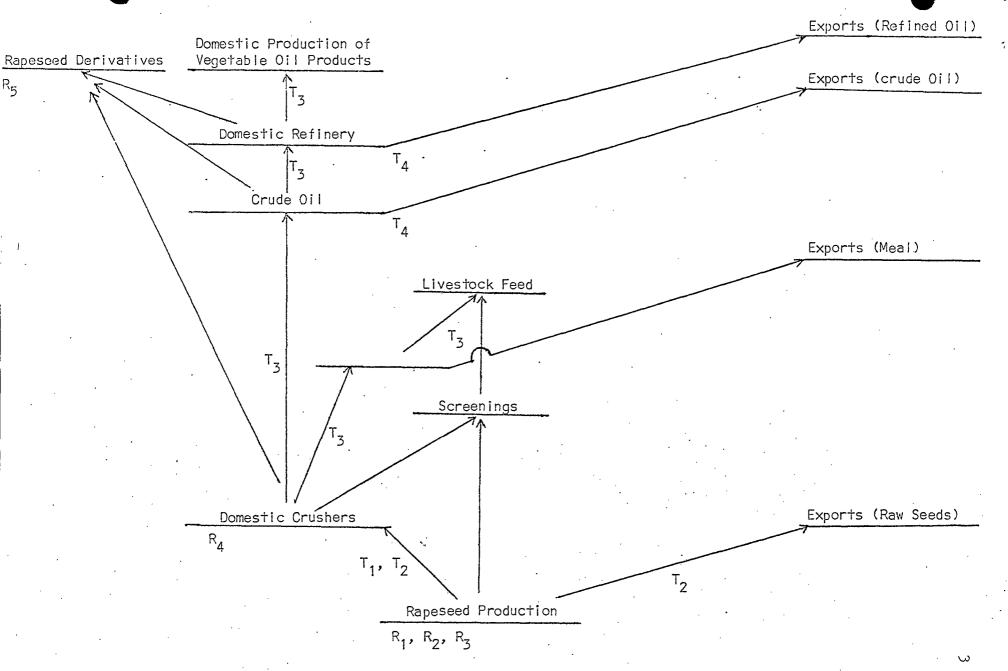

Figure 1. Schematic of Rapeseed Industry

of time required for maturation of rapeseed has been reduced to less than 100 days for some varieties and additional gains are possible.

All else being equal these improvements would strengthen the competitiveness of rapeseed for resource inputs in the Prairie region. This would seem to be desirable on two counts. First, rapeseed has a number of end uses not associated with the end uses of wheat and other small grains. It thus represents a desirable type of diversification of Prairie agriculture. Second, rapeseed is capable of producing more secondary employment through processing than is wheat and other small grains.

Further, to the extent that rapeseed yield rises relative to soybean, its derivatives will tend to become more competitive thus leading to a further penetration of the markets now supplied by soybean both domestically (where the majority of soybeans are imported) as well as internationally. The current United States embargo on soybeans, under which Canada may not be able to obtain its customary requirements in the very short run at least, may hasten the further substitution of rapeseed for soybean.

 $R_2$ 

Improvement in quality of oil. Research is now being directed to the development of varieties of seeds which will (a) have as nearly as possible a zero erucic acid content for human consumption and (b) have a greater than 50 percent erucic acid content for industrial uses. The linolenic acid content of both varieties (now 8-10 percent)

is also being reduced (to a level of less than 3 percent). High linolenic acid content causes rancidity--creates a storage problem. Improvement along these lines will make rapeseed oil more acceptable to buyers concerned with erucic acid content for human consumption. Improved storage quality will reduce the need for refrigeration and lengthen its "shelf life" thus enhancing its competitiveness with other vegetable oils.

<sup>R</sup>3

Improvement in quality of meal. The glucosenolate level of rapeseed meal is sufficiently high to cause a growth problem in non-ruminant animals. (Glucosenolate breaks down into isothiocyanates and oxazolidine-thion which are active goitergens.) This limits the usefulness of the meal as a feed. (Some users—the Japanese in particular—will not feed the meal under these circumstances.) Additional experiments are underway which will reduce the fiber content of rapeseed meal. This will increase the protein content per unit of weight. A lower glucosenolate level and a higher protein content will improve the competitiveness of rapeseed meal with soybean meal.

Development programs in each of these areas have progressed far enough to provide assurance that the goals can be realized. The time required for completion of the programs is still constrained by lack of facilities and support staff, however.

The research bottleneck appears to me now more important than it did at the time of preparing the initial paper. Growth

of the industry in the past has been closely related to solving technical problems of a similar nature. Competition with soybean derivatives and early penetration of the expanding world vegetable oil market would seem to be significantly affected by the timing of these programs.

The CDA research staff in Saskatoon has requested funds from CDA in Ottawa to acquire a growth chamber and supporting equipment as well as to hire additional staff. The request has been assigned a "number two" priority which within the context of the entire CDA operation undoubtedly makes sense. As far as DREE-provincial development objectives for western Canada are concerned, however, an expanded rapeseed research program is of a higher priority.

Two additional research questions are identified in Figure 1.

Pilot plant research facility. At the present time emerging varieties of rapeseed have to be crushed either

(a) in large volume in commercial crushers or (b) sent to research facilities in the United States for testing. Either method is time consuming and use of the domestic crusher requires a larger volume of seed than what would be necessary for a pilot plant. There continues to be a need for a small scale crusher (e.g. 500 lbs. capacity) which would facilitate an early evaluation of new strains. Such things as the influence of pretreatment, variations in time, pressure, temperature, moisture, filtration, etc. on the quality, versatility, and nutritional value of oil, meal and products

could be subjected to a much greater variety of tests than what can currently be achieved.

In the case of the pilot crusher, ITC has indicated an interest in providing financial support subject to agreement (and possible financial commitment) from the industry. Lack of agreement within the industry or possible hesitation regarding financial involvement has stalled the pilot crusher proposal.

Final product research. It seems reasonable to suggest that final product research, now being conducted in three separate locations and again financed by CDA and ITC, would benefit by concentrating it on the University of Saskatchewan campus in Saskatoon in order to achieve maximum continuity and complementarity of the research effort from plant breeding to finished product. Even greater continuity and complementarity could be achieved by combining these endeavors with a more inclusive protein-starch research complex.

Turning to transportation, a bewildering variety of rates and rules apply to the movement of rapeseed and its derivatives. Taken separately each rate and each rule does not appear to be unreasonable. Each rate, except for those established by statute, in fact corresponds to accepted rate-making practice. Looked at as a package or as part of a system, however, the total scheme puts Prairie firms at a considerable disadvantage with respect to their competitors both domestic and foreign.

Transportation to the crusher. First the quota system.

The basic problem was outlined in the original paper. In an

effort to provide "equity" to the farmer, Prairie crushers may sometimes be forced to bring rapeseed from fairly great distances within the Prairie region, even though a supply of rapeseed may be physically present near at hand. An additional source of cost variation is thus forced on Prairie crushers by the quota system which is not forced on off-Prairie competitors (domestic or foreign) since they obtain their raw material at an invariant price. Since the quota is likely to be low in times of excess supply and high in times of excess demand it has the perverse effect of tending to raise costs when profit margins are likely to be low and lowering costs when profits are more likely to be high.

 $^{\mathrm{T}}$ 2

Transportation of rapeseed to off-Prairie points. Raw rapeseed moves to the Lakehead and to west coast ports at Crows Nest Pass rates. The buyer in eastern Canada can have the seed shipped from the Lakehead east by water and of course the overseas buyer ships by water from either port. The point is that both domestic and foreign competitors realize the benefit of these very low rates on assembly of their raw material whereas the Prairie crushers can not. (Rapeseed moves at competitive trucking rates or at domestic commodity rates by rail within the Prairie region.) The Prairie crusher thus competes in Canadian and overseas markets with firms both domestic and foreign whose raw material has been assembled at rates which are subsidized by the Canadian taxpayer.

Transportation of rapeseed products. Rapeseed oil moves T<sub>3</sub> within Canada at domestic commodity rates (or agreed rates). This again appears reasonable considered by itself. Considered in the context of the rates that apply on raw rapeseed, however, this combination has the effect of transferring the cost advantage in crushing and processing to off-Prairie points. (See the example in the original paper.) The recent changes in the rates on the movement of rapeseed products ordered by CTC were in fact very minimal. In essence the cost of shipping rapeseed meal eastward from Thunder Bay was reduced from 79¢/cwt. to 44¢/cwt. This, in effect, extends the Crows Nest Pass rates to movement of meal eastward from the Prairies beyond the Lakehead. Movement of meal within the Prairies and to points west were not affected -- the domestic commodity rate still applies. (In addition the railroads were ordered to file reduced export rates on movement of meal and oil from Prairie points within 60 days.)

 $T_{l\mu}$  In spite of the recent expansion of storage facilities in Vancouver there is still a shortage if substantial exports of oil are to be realized. Apparently storage facilities are at present insufficient to completely load a tanker ship. The loading has to correspond with the timely arrival of rail tank cars.

The future viability of the existing industry could be influenced significantly by modification of the conditions discussed above--i.e. through an expanded research effort and a rationalization of transportation rates.

हिल्लास उत्तर

A selective increase in research effort would enhance the viability of the rapeseed industry by strengthening its competitive position vis-à-vis soybean. It would also tend to strengthen the competitive position of rapeseed for resource inputs. This is desirable both because it represents a meaningful diversification of Prairie agriculture and because the opportunity for further processing is greater than with most other Prairie field crops. In short an increased research effort would have a beneficial effect on the country and the industry regardless of where it is located.

It would appear that DREE could realistically perform the role of catalyst in bringing together various government and industry groups in an effort to encourage more rapid progress and the assignment of a higher priority to the research effort.

The impact of the transportation problem is primarily regional. The current rates and regulations place Prairie crushers at a distinct cost disadvantage with regard to both eastern Canadian and foreign competitors. Elimination of this disadvantage and (very likely) further expansion of the crusher-refiner industry in the Prairies depends upon modification of the existing system.

The most straightforward method of remedying the disadvantage under which Prairie crushers currently operate would be through:

(a) securing a modification of the quota system to insure that Prairie crushers can obtain an adequate supply of raw material on reasonable terms with a reasonable degree of certainty; (b) securing a modification of Crows Nest Pass rate structure so that these rates apply only on movements to export markets and not on any traffic between two points in Canada. With the railroads directed to file low export rates on

meal and oil the above modifications would put Prairie crushers in a much more equitable position with both eastern Canadian and foreign crushers. DREE representation to the Canadian Wheat Board and to the Canadian Transport Commission appears to be the next logical step in this regard.

## EXPANSION OF THE PRESENT INDUSTRY

Agricultural scientists estimate that  $7\frac{1}{2}$  million acres of land in the Prairie provinces could be devoted to the production of rapeseed each year on a sustained yield basis. At 20 bushels per acre this defines a production capacity of 150 million bushels per year.

Maximum exports prior to this year were 47 million bushels (in 1970-71) while the maximum domestic crush was 12 million bushels (in 1971-72). The total of these two figures, approximately 60 million bushels, is about 40 percent of the above estimated production capacity. These crude calculations suggest that there is no primary supply constraint on substantial expansion of the industry.

The significant question then is whether or not demand will increase fast enough to justify an expansion of western crusher capacity.

As indicated in the original paper, rapeseed oil has made substantial inroads into the domestic market for vegetable oils.

(See Table 4b) Further displacement is both possible and likely, but western crushers are not likely to benefit that much from increased use of rapeseed oil domestically. The location of eastern Canadian crushers in the center of the domestic market and the possible loss of the British market for soybean oil strongly suggests that a

substantial part of any increased crush for domestic purposes would take place in eastern Canada. Any increase in western crushing capacity would thus seem to depend on an expansion of overseas markets and especially those in the Pacific Rim.

Many of the persons who make their living from the industry are optimistic about the potential for Canadian rapeseed oil in these markets. Representatives from the industry and from the Canadian Rapeseed Growers Association who have recently been in contact with potential buyers in Korea, the Philippines, Thialand, Japan, and India are very optimistic about market opportunities there. They seem to think that if a large volume of oil could be offered at a competitive price and on a continuous basis that sales could be made immediately. FAO forecasts of demand for vegetable oils through 1980 are consistent with the impression of an expanding market in the Pacific Rim. (See Tables 6a and 6b)

At the present time the four western crushers are capable of processing approximately twice the volume of rapeseed actually being crushed. These firms are heavily committed to the Canadian market, however, either through internal forward integration or through sales to domestic institutional users. While these firms have the capacity to enter the export market it is not their first interest. It would thus seem reasonable to support the development of additional crushing capacity in the west if this capacity were oriented primarily to export markets. Such additional capacity would not disrupt the existing domestic market arrangement and could in fact facilitate penetration of overseas markets by existing domestic firms.

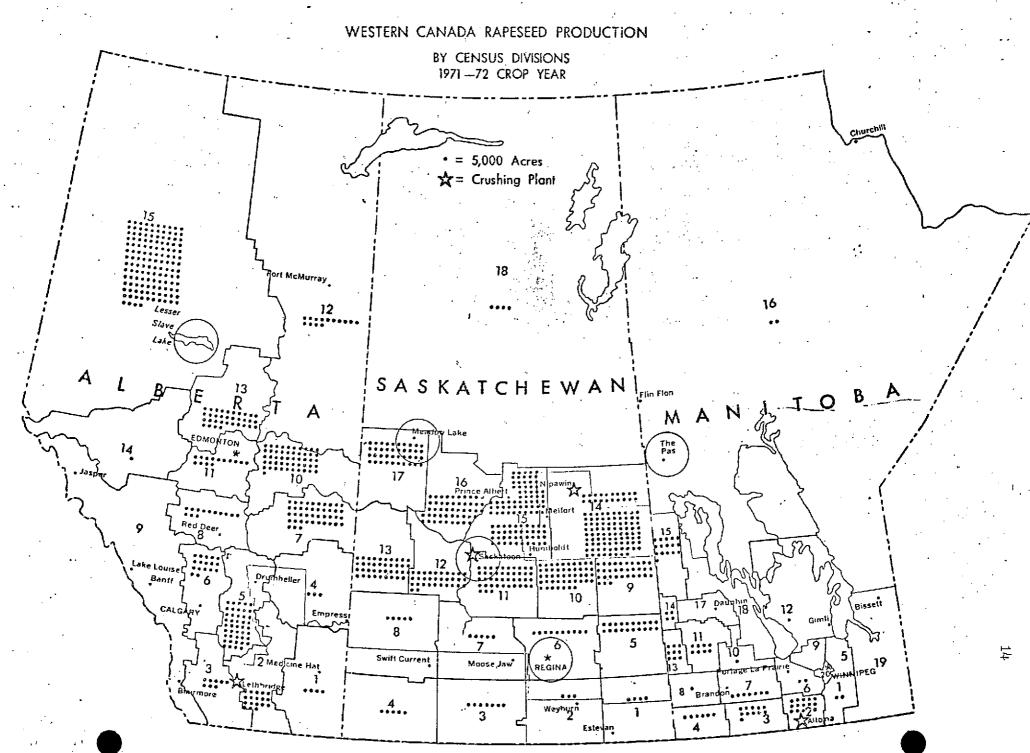

Expanded capacity of the type suggested would lead to an

increase in meal production of course. This would not likely produce a problem. Rapeseed meal is an accepted feed in Canada and if fed domestically in quantities recommended by the Rapeseed Association of Canada its use could expand fourfold. The price relationship between rapeseed meal and soybean meal favors further substitution.

The location of additional crushing capacity in the Prairies is dependent on the availability of a supply of rapeseed, a plentiful supply of water, and adequate transport facilities. Two locations immediately suggest themselves as being favorable in all these respects. These are the Peace River district of Alberta and the North Battleford district of Saskatchewan. A third possible location, but one less attractive than the previous two, is the Yorkton-Roblin area of eastern Saskatchewan-western Manitoba. (See Figure 2)

If groups can be identified who have established that they can dispose of the majority of their oil in overseas markets it would appear desirable to provide financial incentives for them to build in these locations.

A further stipulation should be that plants must be of sufficient size to realize economies of scale in order to qualify for assistance. Most sources identify this size as not less than 600 tons per day crushing capacity.
