CHAPTER 10

ECONOMIC ANALYSIS

SYNOPSIS

The economics of providing water on a regional basis compared to a local scheme of St. John's augmenting its own supply system have been examined in this Chapter. Economic factors such as annual costs, annual revenues, cash flows, and the effect of interest rates, escalation rates and subsidies are included in this presentation. A summary of the findings and recommendations is as follows:

- A staged construction program has been assumed for the economic analysis.
- The economic analysis has been prepared on the assumption that the consumer has paid for the services the project provides by the end of the (economic) life of the project.
- At an interest rate of 8 percent and 0 percent escalation, the charge per 1,000 gallons of water is \$0.64 in the Regional System and \$0.79 in the Local System.
- Effects of changes in interest rates and escalation rates, as well as subsidies on the ultimate charge per 1,000 gallons have been evaluated.

- The cost per 1,000 gallons in the Regional System increases to \$1.22 under the assumption that capital was obtained at 10 percent interest rate and costs escalated at a rate of 5.5 percent per annum.

- The effect of subsidy on the cost per 1,000 gallons of water to the consumer could be as great as \$0.46 under the condition of 8 percent interest rate and no escalation, or as great as \$0.73 under the condition of 10 percent interest and a 5.5 percent escalation rate.

I. INTRODUCTION

Based on an econometric analysis (Chapter 6, Volume II), a regional water conveyance and production system has been developed and recommended upon in Chapters 7 and 8 of Volume III. As noted in the above cited chapters, the City of St. John's, as the central city of the region, essentially forms the core of the proposed regional water system. However, the City of St. John's has had a study carried out for a water supply scheme to supplement the future needs of its own system. This system, referred to in this Chapter as the "local system", supplies water to St. John's, Mount Pearl, Kilbride, Wedgewood Park, Shea Heights. The scheme for the local system has been developed by Canadian-British Engineering Consultants in their reports of 1957 ¹ and 1966 ².

This Chapter examines the economics of providing water on a regional basis compared to the local scheme of St. John's augmenting its own supply system. Economic factors such as annual costs, annual revenues, cash flows, and the effect of interest rates, escalation rates and subsidies are included in this presentation.

II. METHODOLOGY

1. General

For the purpose of this economic analysis it has been assumed that:

- (i) the consumer pays fully for the service the project provides.

- (ii) the project costs are subject to a 0 percent, 4.5 percent or 5.5 percent escalation rate and project funds are available at interest rates of 8 percent, 9 percent and 10 percent per annum. For the local system only an escalation rate of 0 percent and an interest rate of 8 percent have been used.
- (iii) the consumer has paid for the services by the end of the (economic) life time of the project, as stipulated in the ensuing sections of this Chapter.

The cost to the consumer, therefore, consists of the following:

- (a) Land Acquisition Cost
- (b) Design and Construction Costs.
- (c) Equipment Costs.
- (d) Maintenance and Operation Costs.

2. The St. John's Regional Water System

In Chapter 9 of Volume III we have divided the works recommended for the St. John's Regional Water System into 13 packages to be considered in the programming of a staged construction. However, except for initial construction of packages 1, 2 and 3, no scheduling has been recommended for the staged construction of the other packages, as the final decision in this regard

would likely be based on local political and subjective factors. Nonetheless, for the economic analysis presented here, we have assumed a program of staged construction based on engineering considerations. We feel that this program (even though hypothetical), as given in Table 10.1, is of a benefit since it does provide insight as to the economic aspects of the regional supply system.

13	Conveyance main to Penetanguishene including booster station and service reservoir.	0.31	1992-93

Based on the foregoing, and the contents of Chapters 6, 7, 8 and 9, a projected expenditure program (capital and annual) relative to the assumed construction stages of the different packages and the water quantities that will accordingly be used was prepared for the period 1973-74 through 1994-95. This material is contained in Appendix I, and it can be seen from it that the regional water system stipulates the following requirements as related to land, design and construction, and equipment:

- (a) Lands to be purchased are estimated at some 150 acres

for the full project term. This total requirement is comprised of periodic purchases made necessary throughout the life of the project for the purpose of installation of treatment facilities, conveyance mains, pumping stations, reservoirs and the like. Land purchase prices range from \$1,000 per acre to \$2,000 per acre.

For the implementation of packages one and two the purchase price of \$1,000 per acre is assumed. For packages three through eleven the purchase price is \$1,500 per acre, and for the implementation of package twelve it is \$2,000 per acre. The total purchase price of this land over the full project term is estimated at .280 million dollars, based on 1974 dollar value. This figure is arrived at under the assumption that Crown Lands or land currently owned by the Provincial Government and required for this project will be transferred to the project without charge.

Since the land costs are recoverable at the end/or during the life time of the project by re-selling these lands at their original price, for other purposes such as, right of ways, storage areas, park areas, and the like, it is assumed that the cost of land is the cost of money or interest payments calculated on the basis of the initial purchase price (See Appendix III).

The annual cost of land is, therefore, the annual interest payment, calculated on basis of the purchase price of land in use.

The design and construction costs are estimated at 34.635 million dollars based on 1974 dollar value.

Assuming that the construction components have an (economic) service life of 40 years, the annual cost of design and construction is the annual principal and interest payment for this investment amortized over 40 years (See Appendix III). Therefore, the annual payment for design and construction is increased by the annual cost of design and construction investment as the project is implemented.

- (c) Equipment costs which are calculated as a percentage of the total construction costs total 5.475 million dollars based on 1974 dollar value.

It is assumed for the purpose of this analysis that equipment will have a 20 year (economic) service life and a nil salvage value. Thus, the annual cost of equipment is the initial equipment costs amortized over 20 years (See Appendix III).

The above costs are incurred as each new package is introduced into the system. Therefore, the annual payment for equipment is increased by the annual cost of investment in equipment installed as the project progresses.

The annual operating and maintenance costs shown in Appendix III (and discussed in Chapter 6) include power calculated at \$100 per horsepower per year, treatment, administration which includes both operating and maintenance personnel, heating and other similar costs.

3. The St. John's Local Water System

The scheme for the St. John's Local Water System is based on the supply of the entire future water need from Windsor Lake augmented by a new reservoir to be developed on Broad Cove River, and Petty Harbour Long Pond. The originally conceived local system, as developed by Canadian-British Engineering Consultants¹ ², has been updated by us to reflect the following:

- (i) Cost escalation. Components of work and cost included in Canadian-British reports were evaluated for present cost using the Construction Cost Index reported in Engineering News Record.
- (ii) Quantities, quality and pressure of water, and area served by the local scheme - to correspond to that of the Regional System. Accordingly, the total maximum daily water use will be 24.5 MGD. Of this, about 4.5 MGD will be supplied from Petty Harbour Long Pond and 20 MGD from the Windsor Lake - Broad Cove Reservoir System.
- (iii) Costs of components of work not included in Canadian-British reports but required to correspond to the Regional System were taken from the latter estimates.
- (iv) Annual costs. Relevant annual costs were taken from the Regional System estimates.

As in the case of the Regional System, we have assumed a program to implement the local scheme in stages, as shown in Table 10.2.

TABLE 10.2

ST. JOHN'S LOCAL WATER SYSTEM

HYPOTHETICAL PROGRAM OF STAGED CONSTRUCTION

Package No.	Package Description	Estimated Cost (\$M)	Year of Construction
1	Broad Cove Project Stage 1 Development for 2.75 MGD (should have been developed by 1968, consequently, 1968 prices were used for this stage).	0.90	1974-75
2	Broad Cove Project Stage 2 Development to a yield of 6.75 MGD (in lieu of 8.75 MGD as originally recommended, to correspond with the Regional System)	7.00	1974-75 1975-76
3	Pump Station for Kenmount Road - Mundy Pond area.	0.90	1975-76
4	Main Ring at South Expansion Zone (to correspond with the Regional System).	0.85	1976-77
5	Main Ring at North Expansion Zone (to correspond with the Regional System)	0.80	1977-78

TABLE 10.2

ST. JOHN'S LOCAL WATER SYSTEM
HYPOTHETICAL PROGRAM OF STAGED CONSTRUCTION

Package No.		Estimated Cost (M\$)	Year of Construction
6	Service Reservoir at North Expansion Zone (to correspond with the Regional System).	1.00	1987-88
7	Service Reservoir for St. John's Intermediate Pressure Zone plus Facilities for High Pressure Zone (to correspond with the Regional System).	2.20	1982-83 1983-84
8	Service Reservoir for St. John's Low Pressure Zone (to correspond with the Regional System).	1.50	1988-89
9	Windsor Lake Treatment Plant, including improvements to intake (to correspond with the Regional System)	9.00	1985-86 1986-87 1987-88
10	Petty Harbour Long Pond Treatment Plant (to correspond with water quality of Regional System).	4.00	1979-80 1980-81 1981-82
11	24" Diameter Parallel Line to Windsor Lake Main Conduit	0.50	1986-87 1987-88

Based on the foregoing, an expenditure program (capital and annual) relative to the assumed construction stages of the different packages, was prepared for the period 1973-74 through 1994-95. This program is contained in Appendix II, and it can be seen from it that the Local Water System stipulates the following requirements as related to land, design and construction, and equipment.

- (a) Lands to be purchased in addition to the impounding reservoir are estimated at some 75 acres for the full project term. This total requirement is comprised of periodic purchases made necessary throughout the life of the project for the purpose of installation of treatment facilities, conveyance mains, pumping stations, reservoirs and the like. An average land purchase price of \$1,500 per acre has been used.

For the development of Broad Cove reservoir a lump sum of \$500,000 has been considered. The total purchase price of land over the full project term is thus estimated at .610 million dollars, based on 1974 dollar value. This figure is arrived at under the assumption that Crown Lands or land currently owned by the Provincial Government and required for this project will be transferred to the project without charge.

- (b) The design and construction costs are estimated at 24.540 million dollars based on 1974 dollar value over the full project term.

It has been assumed that the construction components have an (economic) service life of 50 years.

Accordingly, the annual cost of design and construction is the annual principal and interest payment for this investment amortized over 50 years (See Appendix IV). Therefore, the annual payment for design and construction is increased by the annual cost of design and construction investment as the project is implemented.

- (c) Equipment costs which are calculated as a percentage of the total construction costs total 5.350 million dollars based on 1974 dollar value.

It is assumed for the purpose of this analysis that equipment will have a 20 year (economic) service life and a nil salvage value. Thus, the annual cost of equipment is the initial equipment costs amortized over 20 years (See Appendix IV).

The above costs are incurred as each new package is introduced into the system. Therefore, the annual payment for equipment is increased by the annual cost of investment in equipment installed as the project progresses.

The annual operating and maintenance costs shown in Appendix IV include power calculated at \$100 per horsepower per year, treatment, administration which includes both operating and maintenance personnel, heating and other similar costs.

III. ANNUAL COSTS AND REVENUES

1. St. John's Regional Water System

The results of the economic analysis showing annual costs and annual revenues for the different escalating rates and fund interest rates as outlined previously in Section II.1 of this Chapter, are contained in Appendix III through Appendix III (H).

Using the data in Appendix III, it can be seen that:

- (i) Annual capital payments account for about 70 percent of the total annual costs. Since these payments are basically fixed, there is relatively little latitude available to reduce annual costs through improvements of efficiency in operation and maintenance. This, however, is not to infer that such improvement efforts should not be practised.
- (ii) Operational losses are incurred in the initial 13 years of the project due to the time elapsed between the original investment and revenue produced. In the later years when consumption has increased, the revenue exceeds the annual cost and surplus is generated.

Under the premise that the system should operate on a self-sustaining basis at all times at a constant rate per 1,000 gallons without generating a surplus, it is necessary to defer the initial losses to a period when a surplus revenue is generated.

The effect of changes in interest rates and escalation rates on the ultimate charge per 1,000 gallons is shown in Table 10.3. It can be seen that on the basis of 8 percent interest rate and 0 percent escalation the water charge is \$0.64 per 1,000 gallons.

TABLE 10.3

WATER CHARGE PER 1,000 GALLONS
AT DIFFERENT INTEREST AND ESCALATION RATES

Interest Rates	Escalation Rates		
	0%	4.5%	5.5%
8%	\$0.64	\$0.97	\$1.07
9%	\$0.69	\$1.04	\$1.15
10%	\$0.74	\$1.10	\$1.22

Note: Table illustrates uniform charge to the consumer per 1,000 gallons necessary to absorb total costs under above escalation and interest rates.

2. St. John's Local Water System

The results of the economic analysis showing annual costs and annual revenues for an 8 percent interest rate and 0 percent escalation, are contained in Appendix IV (A).

Since operational losses are incurred in the initial years, these losses were deferred by borrowing monies and repayment of same in periods of operating surplus.

On this basis the rate per 1,000 gallons is \$0.79 and the working capital requirements are \$466,500 over the first 20 years of operation.

3. Comparison of Regional vs. Local System

The economics of a Regional Water System versus a Local St. John's System have been examined. The results of this economic analysis, as presented above and contained in Appendices III - III (H) and IV - IV (A), clearly indicate the benefits that can be experienced in a regional system.

The charge per 1000 gallons in a Regional System (at 8 percent interest rate and 0 percent escalation) would be \$0.64. Under the same conditions water in a Local System would cost \$0.79 per 1000 gallons. These figures compare to \$0.17 per 1000 gallons in the existing City of St. John's system.

The charge of \$0.64 per 1000 gallons is not unusually high when related to other urban centres where modern water supply facilities are in service. In Oakville, for example, the rate per 1,000 gallons is \$0.58 for consumption between 6,000 and 20,000 gallons and \$0.69 for consumption in excess of 20,000 gallons on a bi-monthly basis. In cities with older systems, such as the City of Toronto, the rate is \$0.41 per 1,000 gallons. The rate per 1,000 gallons in Etobicoke is \$0.52, and in North York a rate of \$0.50 per 1,000 gallons is levied.

On the basis of the above presentation, a cash flow program and the effect of subsidies on water rates in the St. John's Regional Water System have been prepared. This analysis is presented in the following sections.

IV CASH FLOW PROGRAM

Cash flow programs have been prepared for conditions of 8 percent interest rate and 0 percent escalation, and 10 percent interest rate and 5.5 percent escalation rate. These cash flow programs, contained in Appendices V (A) and V (B), are shown to account for the following major groups of cash in flow and disposition on a year by year basis:

- (i) an opening balance.
- (ii) investments representing the annual investment in land, design and construction, and equipment.
- (iii) revenue resulting from the sale of water generated by the project.

- (iv) loans incurred to defer initial losses to a period when surplus revenue is generated.
- (v) working capital necessary to balance the annual fluctuations in revenue and disbursements.
- (vi) installations representing the annual capital expenditures for the project. (See item (ii) above).
- (vii) annual capital repayments representing the annual payments of principal and interest for capital investment implemented by the project to date.
- (viii) operating and maintenance costs.
- (ix) loan repayments representing the annual payments of principal and interest for loans incurred to off set initial operating losses. (See item (iv) above).

It will be noted in Appendix V that the minimum working capital required for conditions of 10 percent interest rate and 5.5 percent escalation rate is \$909,333. The resulting water charge is \$1.22 per 1,000 gallons. For conditions of 8 percent interest rate and 0 percent escalation the working capital required is \$1,204,779, resulting in a water charge of \$0.64 per 1,000 gallons.

V. EFFECT OF SUBSIDIES

In the following, the effect of subsidies on the ultimate charge per 1,000 gallons is described.

For the St. John's Regional Water System the charge per 1,000 gallons may be reduced if assistance were made available to the program through subsidies or grants. For example, compared to the water rates computed in Table 10.3, a grant of 10 million dollars applied to investment will result in a reduction of the cost per 1,000 gallons from \$0.64 to \$0.49 under the assumption of 8 percent interest and 0 percent escalation. A reduction from \$1.04 to \$0.87 would result under the assumption of 9 percent interest and 4.5 percent escalation. A reduction from \$1.22 to \$1.03 would result under the assumption of 10 percent interest and 4.5 percent escalation. The effects of subsidy to capital cost in increments of 5 million dollars on the ultimate rate per 1,000 gallons are illustrated graphically for payments of 8 percent, 9 percent, and 10 percent interest and 0 percent, 4.5 percent and 5.5 percent escalation, in Appendix VI.

It will be noted that the X axis represents the project life expressed in years and the Y axis represents the rate per 1,000 gallons of water. The rate per 1,000 gallons of water would be \$0.64 if no subsidies were applied. Assuming that subsidies or grants are being made available progressing in increments of 5 million dollars as the project is being implemented, that is in accordance with the need for investment funds, the uniform rate for 1,000 gallons of water that is necessary to put the system on a self-sustaining basis would decrease as shown by the curves. Each of the curves accounts for the effects of the assumed interest rate and escalation rate.

VI. CONCLUSION

The costs considered in this Economic Analysis were stated in a 1974 dollar value. These costs were analyzed considering different escalation rates and availability of capital subject to different interest rates.

Costs were defrayed over periods of 1 year, 20 years and 40 years in accordance with the service life anticipated from the expenditure.

It was determined that the cost per 1,000 gallons was \$0.64 under the assumption that capital is made available subject to an 8 percent interest rate and that there was no escalation in costs. The cost per 1,000 gallons increases to \$1.22 under the assumption that capital was obtained at a 10 percent interest rate and costs escalated at a rate of 5.5 percent per annum.

The effects of possible grants or subsidies for investment on the consumer price per 1,000 gallons have also been considered. It was determined that the effect of a subsidy on the cost per 1,000 gallons of water to the consumer could be as great as \$0.46 per 1,000 gallons under the condition of 8 percent interest and no escalation rate or as great as \$0.73 per 1,000 gallons under the condition of 10 percent interest and a 5.5 percent escalation rate.

An in-depth analysis of grants, subsidies or other forms of assistance including the possible sources of the same is outside the terms of reference. Thus the economic analysis confined itself to the theoretical effect of assistance in varying degrees on the price per 1,000 gallons of water to the consumer.

It will be of interest to compare the annual cost of water to a residential customer in the St. John's Regional and Local Water Systems with that in other existing and new systems. Table 10.4 gives this cost comparison.

CHAPTER 11

ORGANIZATIONAL ASPECTS OF REGIONAL WATER MANAGEMENT

SYNOPSIS

Organizational aspects of regional water management have been presented and analysed in this Chapter. Because of the need to proceed immediately with the design and construction of key components of the regional system (identified as packages No. 1, 2, and 3), and the current deliberations to determine among others, the nature, size and policies for a regional government in the north-eastern section of the Avalon Peninsula, the objective of this Chapter is to examine an interim water management organization, and to assess a near "model" water management organization that could be considered and adopted as the ultimate management organization. A summary of the findings and recommendations is as follows:

- Three alternative management organizations have been considered viable to accord with local conditions. These are:
 - Provincially Oriented Organization.
 - Central - City (St. John's) Oriented Organization.
 - Regional Oriented Organization.

- For the interim water management organization the following order of appropriateness is recommended for consideration:
 - (i) Regional Oriented Administration
 - (ii) Provincial Oriented Administration
 - (iii) Central-City (St. John's) Oriented Administration

- Distinction should be made between water resource management and water use management. The former should be administered by the Province; the latter should be the responsibility of the Regional Water Administration.

- Control of watershed activities could be done by enforcement of water protection statutes.

- A regional system, in the idealized definition of the term, suggests production, conveyance and distribution of water. Such a system is undoubtedly a natural function of regional government. It is, therefore, recommended that a regional-oriented water management organization be considered as the "model" for the study region, since it would come closest to fulfillment of the above cited function. It would also be most compatible with future regional government. Flexibility could be employed in the implementation of the above concept of regional system.

- Proposals have been included for the structure of the Regional Water Board, and the structure of the operating departments.

I. INTRODUCTION

1. The Approach

The forecast water supply needs for the St. John's Regional Water System poses a necessity to proceed immediately with the design and construction of key components of the regional system (identified in previous chapters as packages No. 1, 2 and 3). Time constraints, therefore, do not permit the development and establishment of the ultimate management organization to timeously make and administer initial decisions.

In addition, another important and relevant factor which bears heavily on the formulation of an ultimate management organization, at this stage, is the current deliberations to determine among others, the nature, size and policies for a regional government in the north-eastern section of the Avalon Peninsula. It has been considered prudent, therefore, to relate the form of any ultimate water management organization proposed so that it is compatible and can merge with any of the future regional government alternatives currently postulated in another study.

The scope of this chapter is, therefore:

- (a) to study and make recommendations for an interim water management organization, and
- (b) to assess and report on a near "model" water management organization that could be considered and adopted as the ultimate manage-

ment organization, having regard for the constraints of "time" and "local government" as summarised above.

Our basic approach, in defining the aforementioned goals, has been to draw on experience from existing regional water supply administrations, preferably from those that have been studied and reported on in depth as to the factors affecting management. We have identified such a study in the "Institutional Patterns in Evolving Regional Programs for Water Resource Management" by the University of Massachusetts¹.

The first part of this Chapter presents organizational considerations and concepts on regional systems. A study of three alternative management organizations then follows, culminating in recommendations for the interim water management administration.

The second part of this Chapter discusses the different aspects of water management and reports on a possible near "model" organization that we consider could be compatible with alternative future regional government postulations.

2. Alternative Management Organizations

The three alternative management organizations that have been considered viable to accord with local conditions are provincially oriented, central-city (St. John's) oriented, and regionally oriented.

a. Provincially Oriented Organization

This organization would be an agency of the Provincial Government, and would probably have an independent status. Its Administrative Board could comprise of three to five commissioners, one of whom will act as chairman. They would be Provincial appointees, desirably for (contract) terms of some five years. They would probably be full time salaried officials, who should reside in the region, and preferably one at least should be from St. John's.

b. Central-City Oriented Organization

The Administrative Board of this organization and its chairman would be appointed by the Mayor of St. John's (being the centre-city in the region). The Water Department (responsible for system planning and operation) would be a department of the City of St. John's Government.

The Board could include three to five commissioners all of whom might reside in St. John's. Alternatively, provisions could be made for the Board to comprise five to seven commissioners of whom only three or four, respectively, would reside in St. John's, and the remaining members would be from the region at large.

c. Regional Oriented Organization

The basic concept of this organization is that the "user communities" of the regional system would be represented on the Administrative Board, on a

basis reflecting proportional representation, modified by obvious common sense constraints.

Board members could be appointed by the Province as representatives of all the participating municipalities and the province, or as representatives of the larger municipalities, the region at large, and the province. Alternatively, the larger incorporated municipalities could appoint their own representatives while the Province would appoint the provincial representatives and those from the region at large or the unincorporated communities.

The number of Board members would depend on whether the "user communities" are fully or partially represented.

For the interim management organization, however, we envisage an equal representation by the Province and the City of St. John's as a practical, workable and expeditious approach. Each of these two participants could have three or four representatives. In the case of the Province, representatives of various departments with a major interest in the subject service could be appointed to the Board. The City representation on the Board could be from the elected councillors or alternatively, from financial, judicial, engineering and planning entities of the City. The Chairman of the Board would be appointed by the Premier.

Board members would serve overlapping terms. With hold-over members guaranteed, this procedure would yield a reasonable balance between continuity of programming and injection of new and inovative management policies into the decision making functions of the Board.

It is generally well accepted that regional water supply systems should be publicly controlled. Since water belongs to the community at large, the management of water use should come under an administration responsible and responsive to the community at large. From this standpoint, all three alternative management structures must be considered to contain elements of public domain and control.

II. REGIONAL SYSTEM CONCEPTS

There are some basic concepts applicable to any type of management organization which we feel should be taken into account when such an organization is being considered, as they significantly affect the possible objectives, goals and policies of a management organization. These concepts are presented in this section.

1. Availability of Supply

When nearby sources of supply become limited, in quantity and/or qualitative terms, adequate supply has to extend to more remote sources and/or to treated water. This requirement necessitates major engineering at considerable expense. Only a regionally

oriented scheme can reasonably afford adequate intake works, treatment and quality control, pumping and conveyance over a wide area. It is this factor as well as other impersonal variables such as geography, topography, hydrology, economics, engineering technology, population, etc., that are critical in regional program development.

2. Multiple-Service Functions

Though not included in the terms of reference, some relevant thoughts on regional multiple system concepts are given here.

The administration of water supply and (by inference) sewage disposal more or less under the same "roof" appears to be a "natural" consequence of regionalization. Some pros and cons for this multiple-service function are presented below.

The civil engineering involved in sizing and design of pipes and pump stations for both functions are certainly similar. However, those arguing for two separate administrations claim that the treatment of sewage effluent is not related to treatment of drinking water; that sewage disposal agencies do not have to worry about adequacy of supply, or where to obtain it; that water supply agencies worry about delivery, but not discharge; that costing and billing problems are dissimilar.

Those advocating a single multiple function agency claim that the above arguments are primarily valid for systems that are purely local. However, once either function has been regionalized, there is a new perspective to the problem, namely - the type and location of waste water discharges in relation to locations of water supply; the consequences of water supply on waste water discharges and the impact of these two systems on development, rendering of these services across local municipal boundaries and, as such, the extent to which water supply and sewage disposal lines are to be kept separate under ground.

Water supply and sewage disposal are particularly suited as intermunicipal service functions, and hence, both are equally susceptible to the notion of regionalization. It would, therefore, appear that either one administration or two closely co-ordinated administrations, are needed to decide questions raised by rendering these services.

3. Aspects of Law

The enabling legislation, giving authority to, and constraining the operations of the regional agency, irrespective of its administrative orientation, would undoubtedly evolve around traditions and precedents of the Province. It is not within the scope of this study to elaborate on different aspects of law that affect a "regionally" administered program. However, it is felt that some comments

should be included on two most important features of law - the extent to which it is compelling or permissive, and the extent to which it is specific or general.

a. Compulsory vs. Permissive Law

The law creating a water management authority would have to spell out the extent to which the agency functions, to which its terms are binding, and the controls which it can exercise over the municipalities in the region. Acts to this effect could be prepared in a manner that will give the regional agency administrative decision-making discretion ("permissive") in running and developing the system. On the other hand, the law could be detailed ("compulsory") in its specification of what the regional agency may do and how it may do it, forbidding any action without legislative authorization.

b. General vs. Specific Law

General provisions within the law may give direction to the regional agency without dictating means. Detailed legal specifications may set the allowable discretionary range of activity by the regional agency within severe limits. In the former approach ("general") the law would specify the goals to be attained and would leave most of the details on how to attain these goals to the agency it created. The latter ("specific") arrangement could result in the law specifying most of the details of how water supply is to be obtained, how and where

it is to be sold, how programs are to be implemented, how rates are to be structured, how the operating departments are to be structured, and the like. Under these conditions, the regional agency officials would essentially be administering the general engineering details of pipe installation, pumping requirements and the like.

Experience has shown that generally most effective regional management occurs where decision-makers were given maximum discretion and where laws provided policy guidelines without constraining actual administration.

III. ASSESSMENT OF (3) ALTERNATIVE MANAGEMENT ORGANIZATIONS

In this section key factors affecting regional supply management will be presented. The effectiveness and success of each alternative management organization (as previously outlined), having regard for these factors, will then be discussed.

1. Planning

Water supply system planning, even if it strives to be "comprehensive", as in the case of this project, is by nature "incremental". This is primarily so because the planning is based on forecasts which have to and should be reviewed and adjusted, say every five years. These reviews require to be related to longevity of water system life, and its attendant

heavy investment costs, and the fact that decisions once made are very difficult to reverse.

Since water supply systems have substantial bearing on development, a "Central-City" management organization might be suspected by the surrounding municipalities of "self-fulfilling" forecasts. Also, under the specific conditions of this project, decisions would have to be made on the staged implementation of the proposed plan. A "Central-City" decision would be more susceptible to actual and supposed potential conflicts. It is of course possible for the enabling legislation to dictate how the plan should be implemented. This we consider might be a heavy constraint on the "Central-City", as it should have some bargaining power in negotiating the implementation of the program with local municipalities (see also next section).

A "Provincial" administration would eliminate most of the above cited (real and/or imaginary) conflicts. However, the Centre-City (St. John's) may feel that it is "sacrificing" on behalf of the surrounding communities.

A "Regional" agency where all, or at least major participants, have a say in its administration, could resolve planning and implementation of programs in a more democratic manner.

2. Power

Because of the magnitude of cost of a regional water supply system, any expansion to serve municipalities in the area will necessitate a binding commitment from these participating communities prior to construction; that is, there could be no trial period nor any option of withdrawing as a user of the system.

In a "Central-City" or "Provincial" administration, the smaller municipalities would lose their bargaining power once they have joined the system. From the point of view of the smaller municipalities it would be better to form a "Regional" agency so that they could have representation on the governing Board rather than just contract individually with the "Provincial" or "Central-City" agency, and have no specific involvement as to how the system was to be administered.

Opposition to a "Provincial" administration could come from the Centre-City (St. John's) who may feel that it is asked to relinquish some of its jurisdictional prerogatives for the benefit of the smaller municipalities.

Legislative acts might be structured to overcome many of such possible (hypothetical) situations. For example, an act prohibiting communities

in the region from expanding their water supply systems beyond the status and capacity that existed on a certain specified date would give power to the administrative board of a "Provincial" or "Central-City" management to effectively compel municipalities having inadequate supply systems to join the Region. This kind of an arrangement would certainly not be welcomed by the communities as it defeats the basic principle of voluntary co-operation, and the concept of self-determination. At least a tacit agreement of the participating municipalities should be obtained before a regional plan can be effectively implemented. A "Regional" administration would obviously be a more amenable body to seek resolutions along a voluntary and co-operative approach.

3. Authority

When "the chips are down", a "Provincial" agency if so established, would be making regional policy decisions for all the municipalities including the centre-city, while on the other hand, regional questions in a "Central-City" type administration would be decided by a City. This is not to imply that in practice, the above basic difference in authority might be as significant as theory would lead to expect. However, experience does show that a "Provincial" agency usually does not show significant preference (say in rates or type of service) for the centre-city as opposed to out-lying communities. On the other hand, a "Central-City" administration could make city oriented types of decisions.

4. Control Over Distribution

Production of water and its conveyance to municipal boundaries is essentially the practice of "wholesale" water. If one were to add the responsibility of distribution of water to the above functions it would result in the customer service being rigidly controlled from the source to the consumer, by the one agency.

Criteria relating to rates, billing procedures, sizing of local mains, house connections and the like may vary from community to community. Consequently, if a single agency is not responsible for water supply from "pond to tap", the regional conveyance system assessments may be confused by a varied approach as to the efficacy and appropriate charges for a distribution system, leading to (perhaps) inequitable water rates, and differential local service quality.

Local distribution would primarily be dependent on each local capability. Experience has shown excessive differentiation in this regard. Constant and dependable supply of good quality water and at adequate pressure would be guaranteed at municipal connections by the regional system. However, local customers may have no more assurance that their (local distribution) water supply will meet high standards of service than they would have had if the entire service (production, conveyance and distribution) were locally controlled. The full benefit of

regional supply may thus be compromised.

The plan developed for the region includes some conveyance-distribution trunks and service reservoirs within local municipal boundaries (e.g. City of St. John's, Conception Bay South, Kilbride and the Goulds). If water were to be contracted for "wholesale" at the municipal connections, the ownership and maintenance of these types of facility may create conflicts.

Control over distribution is best considered as part of the regional system. It would appear that in terms of short-term goals, this concept could readily be implemented in the smaller communities, whereas the long-term goals, compatible within regional government could include St. John's distribution system.

It is hard to conceive that a "Central-City" administration could control the distribution systems of the smaller municipalities in the region. A "Provincial" administration, with proper and special machinery, could probably do it, but would likely meet opposition, especially from the centre-city. However, policies and formulae are available*, or could be devised to resolve what appears to be a dichotomy (namely, the City losing control of its investment, and by inference its destiny).

* e.g. Acquisition of "Bowaters" water supply by the City of Corner Brook.

5. Equity and Program

There appears to be a significant relationship between the success of water supply regionalization and the extent to which system participants have focused on program rather than equity considerations.

Grounds for development of equity conflicts are more profound in a system containing "middlemen" who charge "retail" mark-up on "wholesale" rates; that is, local municipalities charging water rates for distribution on top of the rates charged by the region for production and conveyance of the water to the municipality.

Free negotiations for membership in the region, including acquisition of any local facilities so that there is no double responsibility, the provision of only a single ownership by the region of the capital plant, and all rights to its maintenance, would result in unity of command and substantial absence of the "issue". Such a system could be standardized because the region is "in charge" throughout the district. Member municipalities could not argue inequitable rates (except by comparison outside the region), neither could they argue jurisdictional equity because they would have no jurisdiction whatever over the function. In the developing and implementation of programs, the region's sole concern would be that of quality of service, planned well into the future.

Again, the "Regional" administration would appear to be the best suited and most acceptable to provide and control this function. Implementation of this concept could entail short and long terms goals as discussed earlier.

IV. SUMMARY AND RECOMMENDATIONS

A regional system, in the idealized definition of the term, suggests production, conveyance, and distribution of the water. Such a system provides the best possible quality of service and virtually eliminates conflicts. It is undoubtedly a natural function of regional government. However, in the absence of the latter, a regional-oriented water management organization would come closest to fulfillment of this function. It would also be most compatible with future regional government.

Flexibility could be employed in the implementation of the above concept of regional system. During the interim period until regional government is formed, the smaller municipalities could be fully regionalized within the system. Eventually, this could expand to include the entire region.

In the regionalization of a water supply system, local municipalities would have to relinquish their rights to certain jurisdictional prerogatives. A full or partial partnership in a "Regional" administration may be considered a compensation and substitute for this sacrifice. Although

in special cases (e.g. St. John's perhaps relinquishing source rights, etc., or Wedgewood Park relinquishing distribution rights) particular agreements may be necessary to protect established equity and future independence. These matters of course, apply to the whole sphere of municipal infrastructure which must be resolved under the "umbrella" of "total regionalization".

From the preceding discussion and experience, it could be said that smaller municipalities would prefer to rely on a "Provincial-oriented" water management organization rather than a "Central-City" one, whereas the centre-city may be very reluctant to relinquish its rights to existing or planned programs unless an adequate and satisfactory arrangement can be worked out. However, for a regional system to be effective and economical, participation should be by both the centre-city and the smaller municipalities. To achieve this end, more than a resemblance of co-operation is required.

Among the three types of management organization presented, it is recommended that the following order of appropriateness be considered:

- (a) Regional oriented administration.
- (b) Provincial oriented administration.
- (c) Central City (St. John's) oriented administration.

Possible structure of the Administrative Board of each organization has been presented in Section I of this Chapter.

It is further recommended that recruitment for the operating staff start as soon as possible with the hiring of a project manager, who would eventually become the key technical member of the agency upon its formulation.

A detailed discussion of water management aspects leading to a near "model" management administration and organization structure is presented in the second part of this chapter.

V. BASIC MANAGEMENT CONCEPTS

1. General

Management concerns itself with three basic types of processes, namely:

- (a) Goal Determination - this process involves forecasting, planning, co-ordination, liaison, negotiation and consultation operations.
- (b) Realization of Goals - encompassed in this process are all the services required for production, technical support, undertaking of control and tutelage.

- (c) Provision of Means for the Determination of Realization of Goals - this process includes all administrative services such as personnel, purchasing, financial, legal.

The vehicle with which management executes the above basic processes is the administrative organization. It would, therefore, be appropriate to define here some key administrative concepts and techniques relating to organization.

2. Administrative Activities and Operations*

a. Categories of Activity

In virtually every area of administration five basic categories of activities may be identified as they relate to this study's central interest. These categories are as follows:

- (i) Administrative activities concerned with the improvement of knowledge. This may include the upgrading of local conditions and requirements related to water supply, as well as the provision of technical, scientific and economic information and data, all as needed to prepare long range forecasts and planning.
- (ii) Administrative activities related to the operation-production of services. These activities are concerned with the operations by which the administration produces the water for supply to the communities within its region.

* The framework for this section was taken from Reference 2 modified to suit this project.

- (iii) Administrative activities concerned with conveyance within the administrative area. Such activities ensure that the interested communities in the region will have water conveyed to within their municipal boundaries.

- (iv) Administrative activities related to protection and security in the provision of services. This involves the application of measures designed to maintain water supply of a designated quality, quantity and pressure.

- (v) Administration activities concerned with improvement-development of the services. This may involve the expansion of facilities to improve and/or add production and conveyance capacities of water to any given part of the region.

Given these five categories of activity, the next area of concern is how are they carried out? The following section deals with the topic.

b. Types of Operations

Ten different kinds of operations may be distinguished, as follows:

- (i) Those contributing to the collection and analysis of data. They may include surveys, censuses, investigations, experiments, data processing, and preparation and presentation of reports that cover such aspects as:

- (a) Forecasts for water supply based on dynamic changes in local conditions and requirements.
 - (b) Technological and economic developments whose application may improve and/or economize the services rendered by the administration.
 - (c) Annual operating, financing and inventory statistics.
- (ii) Those contributing to planning. They should include the development of objectives, and the formulation and application of policies to meet those objectives.
 - (iii) Those that are related to the production of water. This is concerned with the actual performances by an administrative department of mechanical operations of intake and treatment works that lead to the production of water.
 - (iv) Those that are related to the supply of water. This is concerned with the actual performance by an administrative department of mechanical operations and maintenance of conveyance mains and pumping stations that lead to the supply of water to the communities within the administration's region.

- (v) Those by which the administration puts equipment to extend and improve water supply to the interested communities within its region. This would include construction activities such as extensions of conveyance mains and treatment, pumping and storage facilities.
- (vi) Those concerned with finances. This may involve such programs as price setting, issuance of debentures, arrangement of grants and subsidies.
- (vii) Co-ordination of operation, both within the various administrative departments and among intra administration and governmental agencies, in order to make their action cohesive and complementary.
- (viii) Those by which the administration exercises controls and renders services to public agencies or private individuals. These operations involve such matters as control of activities in the water-shed, rights of ways, standardization of equipment and material, supervision, inspection, conciliation, approbation of plans and standards, reviews of specifications.
- (ix) Negotiation and advice-information operations by which the administration comes in contact with the interested communities within its region in order to realize a common objective.

- (x) Those by which the administration gives assistance to various parties. This is concerned with advice, information, data dissemination, promotion, lectures, films, publications.

The foregoing discussion has outlined five major categories of administrative activities, and ten broad types of operations which might be undertaken in connection with these activities. It would be appropriate at this stage, prior to defining the administrative organization for St. John's Regional Water System, its departments and their roles, to examine the following:

- (a) Specific characteristics of water management for the study area which would make its administration different from that of other administrative areas.
- (b) Research project(s) of existing administrations of regional water systems.

VI. SPECIFIC ASPECTS OF WATER MANAGEMENT

Water management requires the examination of specific functional characteristics that significantly bear on its administration. These are the community characteristic, the multifunctional characteristic, and the mobility characteristic.²

1. Community Characteristic

Water is vital to everyone and is generally accepted as a "community vocation". As a general rule, water is regarded as unappropriable since it fulfills a universal need, and does not have to be restricted by political boundaries.

Water, whether stagnating or flowing, is located over land. This land may be under Crown, public, or private ownership. The title to Windsor Lake watershed land, for example, is shared by the City, the Province, and private individuals. There follows an obvious problem of defining the relation between both the management of water and the land over which it is located. Since the goals of water management essentially differ from the goals of land management, the former being necessarily public (as required by the community vocation of water), but not the latter, a distinction between water management and land management seems warranted.

2. Multifunctional Characteristic

As a resource, water may be used for various purposes simultaneously. Bay Bulls Big Pond Water, for example, is used for power generation, recreation, maintenance of down-stream flows, and is now being recommended for development as a source of communal water supply.

The multifunctional aspect of water use leads to two types of management concerns. First, there is the need to determine allocations and priorities among

the competitive uses of the resource. Second, there is the need to establish management responsibilities of the resource. There follows, therefore, a distinction between the responsibilities concerning water resource management and water use management. The first area of concern requires an administration which should be specifically responsible for the water as a resource, ensuring the preponderance of the conservation objectives over irrational objectives, as far as the future is concerned. However, once the use(s) of a water resource has (have) been authorized, a water use administration should be created to accept management responsibility over this specific resource.

3. Mobility Characteristic

Since water is "mobile", a given administrative activity in a given location may result in defects elsewhere in the catchment, or in defects at a later time in the same place. This means that activities such as water withdrawals for power or other purposes, disposals, recreation, may compromise the potential quality-quantity capability aspects of the water resource. For this reason, it seems warranted to distinguish water use activities from quality-quantity control activities.

4. Practical Implications

The significance of the characteristics outlined above in relation to administration and management of a water system is that (water) management

responsibilities should be vested in two different administrations, as follows:

a. Water Resource Administration

This management institution will be responsible for all the water resources (watersheds) with conservation objectives being its prime policy. It will authorize water uses and will participate in, or will exercise supervision over, the water use management organizations. It will bear ultimate responsibility for the quality-quantity control of the water use resource. By the nature of its functions, this should be a provincial government administration. Indeed, such responsibilities have been bestowed on a number of ministerial departments, as will be seen in the next section. There is also local precedent of authorization of water uses and management of water use. Examples are Windsor Lake, authorized to be used by the City of St. John's which also bears management responsibilities, and Bay Bulls Big Pond which is being used and managed by the Newfoundland Light and Power Company.

b. Water Use Administration

A management organization should be created specifically for the water use administration of definite water resource(s). The water use could be single or multiple purpose. Because of the essentially public nature of the responsibility concerning water use management, a public agency of an administrative nature would be preferred for this task. This administration will be

responsible for the activities and operations outlined previously in Section V.2 of this Chapter. The crux of the next part of this Chapter is to define the administrative agency proposed for the St. John's region, and propose a formula to organize same.

VII. WATER RESOURCE MANAGEMENT

1. Existing Management Policies

The property in and the right to the use, and the flow of all water in the Province are, for all purposes, vested in the Crown. The Province, however, under any statute, valid grant, lease, licence, or other instrument, may confer rights of property, use and flow of water on any municipal authority or person (excerpts from the Department of Provincial Affairs, and Environment Act, 1973).

The above cited policy appears to support our basic concept of two levels of water management, namely resource management and use management. Furthermore, we feel that existing legislative Acts provide an adequate tool for the Province to effectively manage its water resources. A review of key Acts that may have a bearing on this study, in terms of water resources conservation and control, and authorization of water use, are presented below.

a. The Department of Provincial Affairs,
and Environment Act, 1973.

This is an Act that provides for the abatement and control of pollution of air, soil and water, and for the conservation and use of water as a natural resource of the Province. It provides an aid toward the centralization and coordination of the multiform controls over the use of water, generally, by the creation of an authority as an arm of government.

The Department of Provincial Affairs and Environment is responsible for the administration of this Act.

b. The Waters Protection Act, 1964.

This is an Act to secure the purity of water. "The Minister of Health shall have the general oversight and care of all inland waters, whether standing, running or below ground, for the purpose of keeping them wherever possible fit for drinking and domestic purposes and free from any condition which is or might be injurious to the public health."

c. Department of Health Act, 1965

This Act provides for the "preventing the pollution, defilement, discolouration or fouling of all lakes, rivers, streams, pools, springs and waters, so as to ensure their sanitary condition."

Another responsibility bestowed on the Ministry of Health is the protection of water supply sources under the Public Health (Sanitation) Regulations, 1963.

d. Other Acts pertaining to water resources control management include the Waste Material (Disposal) Act, 1973 (under the Minister of Provincial Affairs, and Environment), and the Pesticide Control Act, 1970 (under the Minister of Provincial Affairs and Environment).

e. Local Government Act, 1966

This Act pertains to water use as it states that the "establishment of a public water supply system is subject to the approval of the Minister of Municipal Affairs and Housing".

f. Other Acts pertaining to water use include the Crown Lands Act CH174 RSN1952, which authorizes water leases for power generation (under the Minister of Mines and Energy).

2. Controlling Watershed Activities

The Provincial Government through statutes and authority, bestowed on two ministerial departments (Provincial Affairs and Environment, and Health) conserves and controls its water resources. However, once the Province authorizes the use of a water resource for public supply and approves the water supply system (through the Departments of Municipal Affairs and Housing, and Provincial Affairs and Environment), a more stringent control of watershed activities may be required, to ensure that the source water quality is sustained in a condition most compatible with the capability of any proposed treatment facilities, to produce

water quality of the adopted standards. Various means are available for this purpose, and the two most effective ones, purchase of watershed lands and enforcement of water protection statutes, are discussed in this section.

a. Purchase of Watershed Lands.

Purchase of all of the watershed lands gives complete control over the activities that take place in the area. In some cases, the purchase of only the lower lying watershed lands will provide the necessary protection.

b. Enforcement of Water Protection Statutes

The Department of Provincial Affairs and Environment Act (1973), and the Waters Protection Act (1964), contain provisions to protect public water supply sources. Enforcement of these Acts lies with the Province, the former being the responsibility of the Environmental Management and Control Division of the Department of Provincial Affairs and Environment; the latter is the responsibility of the Department of Health.

An examination of the above two protection methods relative to the two sources of supply for the St. John's Regional Water System implies the following protection strategy.

c. Protection Strategy

(i) Windsor Lake Watershed

The watershed lands are owned by the City of St. John's, the Crown and private enterprise. Water use management is bestowed on the City of St. John's which utilizes Windsor Lake as a source of supply. There are only limited residential activities in the watershed, and they are confined to the upper watershed area. All other activities are strictly controlled by enforcement of water protection statutes. The sanitary survey that we have carried out within this study (see Chapter 5) indicate that although this protection method is reasonably effective, more stringent enforcing measures would be desirable.

(ii) Bay Bulls Big Pond Watershed

The watershed lands are owned by the Crown and private enterprise. Substantial portion of the watershed is owned by the Newfoundland Light and Power Company. Water use management is presently the responsibility of that company which utilizes Bay Bulls Big Pond as a source for power generation. There are limited residential activities in the lower watershed area, and limited commercial and agricultural activities in the upper reaches of the watershed. Water based recreational activities are also conducted in the watershed. Except for a relatively recent freeze on new development, there as yet has been no significant enforcement of water protection statutes that we could determine.

In view of the above conditions, the results of our sanitary survey (see Chapter 5) indicate that Bay Bulls Big Pond water is not of (too) inferior quality, despite development in the catchment. Having regard for the type of treatment recommended for this source water (see Chapters 5 and 8), and in light of the experience at Windsor Lake, we feel that water use management oriented towards public water supply with strict enforcement of water protection statutes will provide the degree of control desired for this watershed.

3. Practical Implications

Rights of property and water use management of resources utilized for public water supply, be it a single use (as in the case of Windsor Lake) or one of multiple uses (as in the case of Bay Bulls Big Pond) should be conferred by the Province on the agency responsible for administering that water supply system. The quality-quantity balance requirement in water use management is by far a more dominant factor when the resource is to be utilized for public water supply.

By conferring water use management rights on the St. John's Regional Water System administration, the Province should not relinquish its responsibility to determine allocations of water, in case of competitive uses, nor the responsibility for strict enforcement of water protection statutes. However,

to carry out these functions effectively and successfully, a co-operative and co-ordinated relationship should exist between the water resource management organization(s) (i.e. the Province) and the water use management agency (i.e. the St. John's Regional Water System administration). For example, it is often claimed that a provincial organization is by its necessary nature not able to timeously enforce and strictly adhere to water protection statutes. We envisage in this regard, therefore, that the St. John's Regional Water System administration should carry out rigorous sanitary surveys and accordingly file complaints with the Province.

To best assist the Province to act promptly and efficiently on such complaints, a provincial participation in the latter administration should be considered. This provincial participation will in turn provide the administrating organization with a "platform" to present their views on water allocations.

VIII. WATER USE MANAGEMENT

1. The Approach

In considering the organizational structure of the St. John's Regional Water System administration for water use management purposes, we have taken the following basic approach:

- a. This administration should be a public one because its status must be of the same type as the responsibility that has been bestowed upon it. Since water belongs to the community, the management of water use should come under an administration responsible to the community (from a statutory standpoint).
- b. Experience should be drawn from existing regional water supply administrations, preferably from ones that have been studied in depth and reported on as to the factors affecting management. We have identified such a study in the "Institutional Patterns in Evolving Regional Programs for Water Resource Management" by the University of Massachusetts¹.

2. Comparing Regional Water Supply Systems

A team of researchers from the University of Massachusetts studied in depth, over a period of some three years (from 1967 to 1970), four regional water supply systems, their organizational forms and service functions. A resume of these four (4) systems is presented below.

a. Boston Metropolitan District Commission (MDC)

A regional system of water supply, sewage disposal, and parks (with minor activity in boulevards and solid waste disposal), developed around the turn of the century. An agency of the state with compelling legal constraints and a heavy focus on equity

considerations. Territorially extensive but not consolidated. Water supply system services some 2,000,000 people in 43 municipalities. Agency supplies and transmits water; local communities distribute. Wholesale price: \$120 per m.g., but is generally less outside the District. As presently constituted, MDC is administered by a Commissioner and four Associate Commissioners, all appointed by the State.

b. Detroit Metropolitan Water Services (DMWS)

A regional system for water supply and sewage disposal developed on a "reluctant" basis from 1950 to 1954 and on a positive expansionist basis since. An agency of the centre-city (Detroit) with very few legal prescriptions and considerable policy discretion which reflect constant changes due to changes in policy making personnel. Territorially extensive but not consolidated. Water supply system serves roughly 4,000,000 people in 84 municipalities. Agency supplies and transmits water; local communities distribute. Wholesale price: average \$150 per m.g., but varies according to managerial costing criteria. DMWS is administered by a Board of seven Water Commissioners, four of which must be from Detroit, appointed by the Mayor. The latter also designates the President and Vice-President of the Board of Water Commissioners.

c. Springfield Water Department

A regional system, for supply of water only, developed primarily between 1910 and 1930. An agency of the

centre-city (Springfield) with considerable dependence on special acts of the State Legislature. Territorially limited and consolidated, but members are loosely federated, and frequently seek independence from the Springfield supply system. System serves some 250,000 people in nine municipalities. Agency supplies and transmits water; local communities distribute except in one case. Wholesale price: \$125 per m.g. The Springfield Board of Water Commissioners comprises three members, the Mayor and two Commissioners appointed by the Mayor.

d. Hartford Metropolitan District Commission (MDC)

A regional system for water supply and sewage disposal with minor activity in regional planning and highways, and authority to give regional solid waste disposal service. Developed since 1929, a quasi-agency of the state with compelling general prescriptions, but with considerable discretionary power over details of policy. Financial practices indicate attention to quality of service and inattention to problems of equity. Territorially limited and consolidated. Water supply system serves some 400,000 people in 10 municipalities with additional minor service to small areas along its supply lines. Agency supplies, transmits, and distributes water except to one municipality which has its own distribution system. There is no general wholesale price and therefore, retail price is on a sliding scale based primarily on volume of use. Retail cost, on average, is probably slightly higher than in the Boston and Springfield systems, but close

to cost in the Detroit system. The Commission, the governing Board of the District, comprises 22 members appointed by the State. Seven are appointed as representatives of the member city and towns for 2 year terms, and 15 are appointed at large for 6 year overlapping terms.

Following is a review of what the researchers considered to be the most important findings resulting from their extensive investigation of the four regional water supply systems.

- (i) Extent of population around the urban core and availability of local alternative water supply sources are the two most important factors dictating size of territory covered by the regional supply system. These are the inexorable, limiting variables. If the population is too sparse, or local communities have local water supplies, they can develop easily, there is a tendency for each community to develop its own water supply system and to resist federation into a larger water supply network. By the same token, regional supply systems tend to grow only where population is concentrated, and other supply alternatives do not exist or can only be obtained at prohibitive cost.

It should be noted here that the approach taken in our econometric model study is essentially in line with this finding.

- (ii) Despite the pre-eminence of these (above) two compelling factors, the general type of organizational framework, within ("to shape a region") which the regional water supply decisions are made, (was also found to) make a difference. In this regard, two important variables were determined - the extent to which agency orientation is toward the region or toward the central city as a specific entity in the region; and the extent to which local "home rule" is operative either by dint of a formal grant of powers by the (Province) or by dint of informal "home rule" traditions.

The researchers believe that the placing of regional responsibility on central-city agencies has hampered the efforts of both Detroit and Springfield to regionalize water service in the full sense of the word, that is regional production, conveyance and distribution of water.

The researchers found that Hartford MDC, as a model of multipurpose state-sponsored regional administration, may serve to highlight the advantages of control by a level of administration somewhere between local and state control.

- (iii) Constraints on administration were also found to be important. Both expertise and tenure appear to be significant factors affecting quality of regional decision-making in the areas of both policy and administration. Quality of

decision-making was found highest where qualified, career administrators were given substantially free reign to decide the best course of action.

- (iv) The number and type of services offered by the regional agency were found to affect regional "success". While agreeing with Springfield officials that there are theoretical justifications for single purpose administration, the researchers noted that the joint administration of both water supply and sewage disposal seemed to be a positive factor encouraging regional government. Yet, the accretion of unrelated services beyond these basic two, by a regional agency, can serve to impair the effectiveness of any one service by atomizing the amount of attention given each. This seemed especially true for unrelated services such as park administration.
- (v) A Corollary of the multiple agency question is the multiple customer question. At the very least, there is evidence that differences between domestic and industrial customers can be important.

Major industrial customers can be an important influence either constraining, or encouraging regional water supply development. Whether "constraining or encouraging" depends on the circumstances and political orientation of both the industrial customers and the regional authorities. However, where industrial customers

use large volumes of water, their desires (i.e., what is best for the industry) can usually be imposed on the regional decision makers.

(vi) The number and type of legal enactments governing the regional agency and its relations with other agencies were found to be important, especially with respect to how general or specific and how compelling or permissive they (enactments) are. Generally, most regional management was found where decision-makers were given maximum discretion and where laws provided policy guidelines without constraining actual administration.

(vii) A final factor influencing regional "success" was found to be the extent to which agency administrators are required to consider, or voluntarily engage in consideration of, extraneous or tandem problems such as fiscal or jurisdictional equity questions or personnel matters. This relates to point (vi) above in that such concerns are often dictated by legal enactments; but also, there appears to be an idiosyncratic personality factor involved such as whether the administrator has an inclination to make political or technical decisions.

Certain organizational forms appear to encourage a focus on service quality and away from equity concerns. One most important factor was found

to be whether or not local communities are given a substantial part to play in the regional operation. Where the regional program amounts to a federation of quasi-independent local units, equity concerns predominate. Where the regional program is administered by an agency with substantially full control of regional program, the emphasis tends to be on quality of service and equity problems tend to be minimized.

3. The Organization Structure

There are two elements to be considered in the organization design, the structure of the Board, and the structure of the organization operating the day-to-day functions. On the basis of previous discussions, these are presented below.

a. Structure of the Board

Representation on the Board would be held by each community within the regional water system, and provincial government delegates. A proposed representation on the Board is shown in Table 11.1. Participation on the Board for water resources and system development matters, would be by all representative members, however, participation in financial obligations would commence upon consumption of water by a community.*

* To accord with Regional Water Management (or Original Government) formulations, it might be that communities in the region-at-large who do not (or will not) receive water from either of the major regional sources, nevertheless might wish member participation. The level of participation, however, would probably vary from community to community depending on their needs (e.g. inability to maintain their system or protect their source, etc.)

TABLE 11.1

PROPOSED REPRESENTATION

ST. JOHN'S REGIONAL WATER SYSTEM BOARD

<u>COMMUNITY/GOVERNMENT</u>	<u>REPRESENTATIVE</u>	<u>BOARD MEMBERS</u>
Department of Municipal Affairs and Housing	Delegate	1
Department of Provincial Affairs and Environment	Delegate	1
Department of Health	Delegate	1
City of St. John's	Mayor and Two Delegates	3
St. John's Metropolitan Area Board	Board Chairman	1
Town of Conception Bay South	Mayor	1
Town of Mount Pearl	Mayor	1
New Town Mount Pearl	Appointed by N. & L. H. C.	1
Region At Large	Provincial Appointee	2
		—
Total Membership of Board		12

Responsibility for the Board would lie best with the Minister of Municipal Affairs and Housing.

We have not attempted to define in detail the role and/or responsibilities of the staff of the management organization since many variables (i.e. type of future Regional Government, possible joint "Sewerage and Water Board"), which have to be determined outwith this particular study's remit will obviously affect size, shape and other aspects of a "management agency" for the Region's water or other municipal services infrastructure. Also, it is perhaps obvious, but bears mentioning, that the goals size, shape and other features of the tentative target organization postulated, will tend to be self modifying as allotted fiscal programmes are made and with the passage of time.

The Board members, who should be unpaid, will take an active part in administrative decision-making only when presented with questions by the staff. Various sub-committees could have recommendatory functions on various aspects of agency activity. Experience at Hartford, Connecticut, demonstrated that quality of decision-making was highest because career administrators were given substantially free reign to decide the best course of action. It is accordingly recommended that this approach be adopted in this case, and the Board members would act as the agency giving a stamp of officialdom to what are basically staff recommendations.

It is further recommended (based on Hartford, experience), that the Board be given maximum discretion; that is have the laws provide policy guidelines without constraining actual administration.

It is also recommended that the Board concern itself with long range planning as a first priority rather than concentrating on maximum dollar value.

Whereas this study was based on the premise to supply water in bulk to community members (through production and conveyance only), it is recommended that these communities be encouraged to entrust with the Board the responsibility to distribute water within the community. This will ensure efficient and high quality service.

Another point of interest found in the study of the "four regional water supply system" is the merit of having the water supply and sewage disposal agencies under the same administrative roof. We would advocate that this approach should be considered in due course when the formulations for waste treatment in the general area of this (water) study are complete.

b. Structure of Operating Organization

Under the directorship of a career General Manager, five general departments will operate:

- (i) Planning, Engineering, and Technical Services.
- (ii) Treatment Plant Operations.
- (iii) Water Supply System Operations.

- (iv) Administrative Services
- (v) Treasury

Figures 11.1 through 11.6 show the general structure of these departments, and identify the major categories of work force. This proposed structure is not necessarily final, and some modification may be required prior to implementation.

The functions and responsibilities of each department, relative to the ten different kinds of operations as distinguished in Section V.2.b. of this Chapter, are envisaged to be as follows:

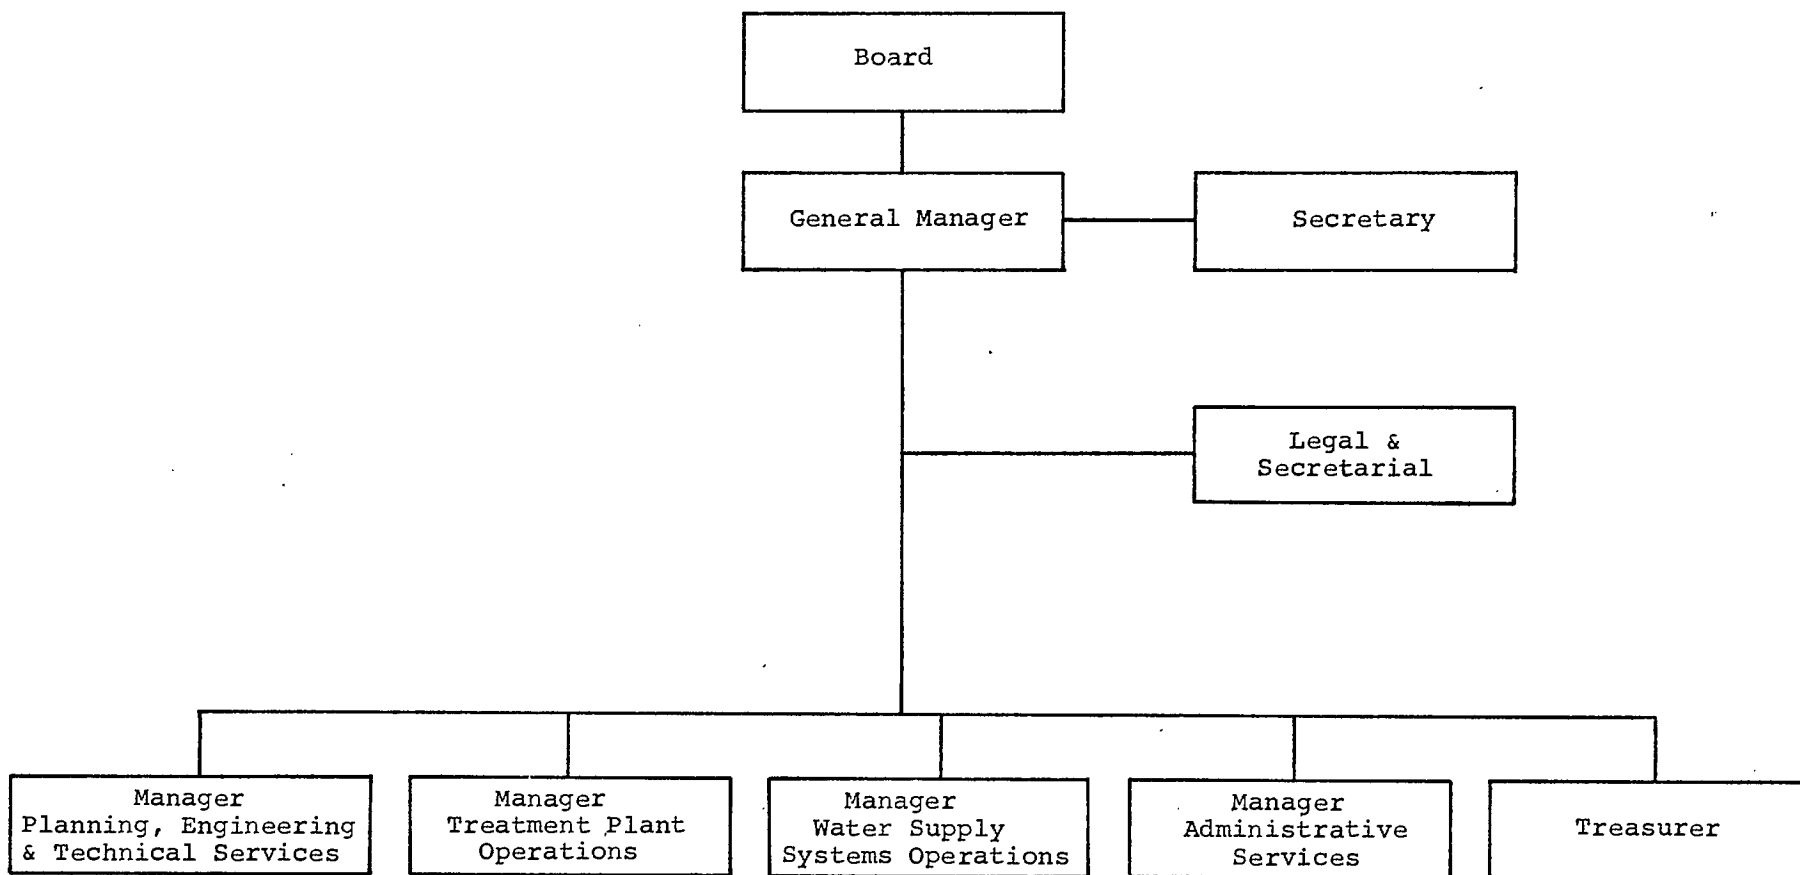

- (i) Planning, Engineering and Technical Services (Fig.11.2)

This department will render key engineering services.

The planning section will develop long range design objectives, and formulate application policies for implementation of these objectives. Terms of reference for future works will be drawn-up by this section for undertaking by in-house forces or outside consultants. In-house design activities will be the responsibility of this section. Liaison with outside consultants will be through this section.

The construction section will supervise all construction activities such as extensions of conveyance mains, and treatment works, pumping and storage facilities, undertaken

FIGURE 11-1

FIGURE 11-4

FIGURE 11-5

FIGURE 11-6

FIGURE 11-2
DEPARTMENTAL ORGANIZATION

11.47

FENCO

by in-house forces or outside contractors.

The technical studies section will carry out surveys, censuses, investigations, experiments, data processing and other similar activities covering such aspects as:

- (a) Forecasts for water needs and supply.
- (b) Technological and economic developments that may improve and/or economize services.
- (c) Standardization of equipment and material.
- (d) Annual operating, financing and inventory statistics.
- (e) Watershed water quality.

The above three sections will have a supporting staff of surveyors and draftsmen to assist them in their work.

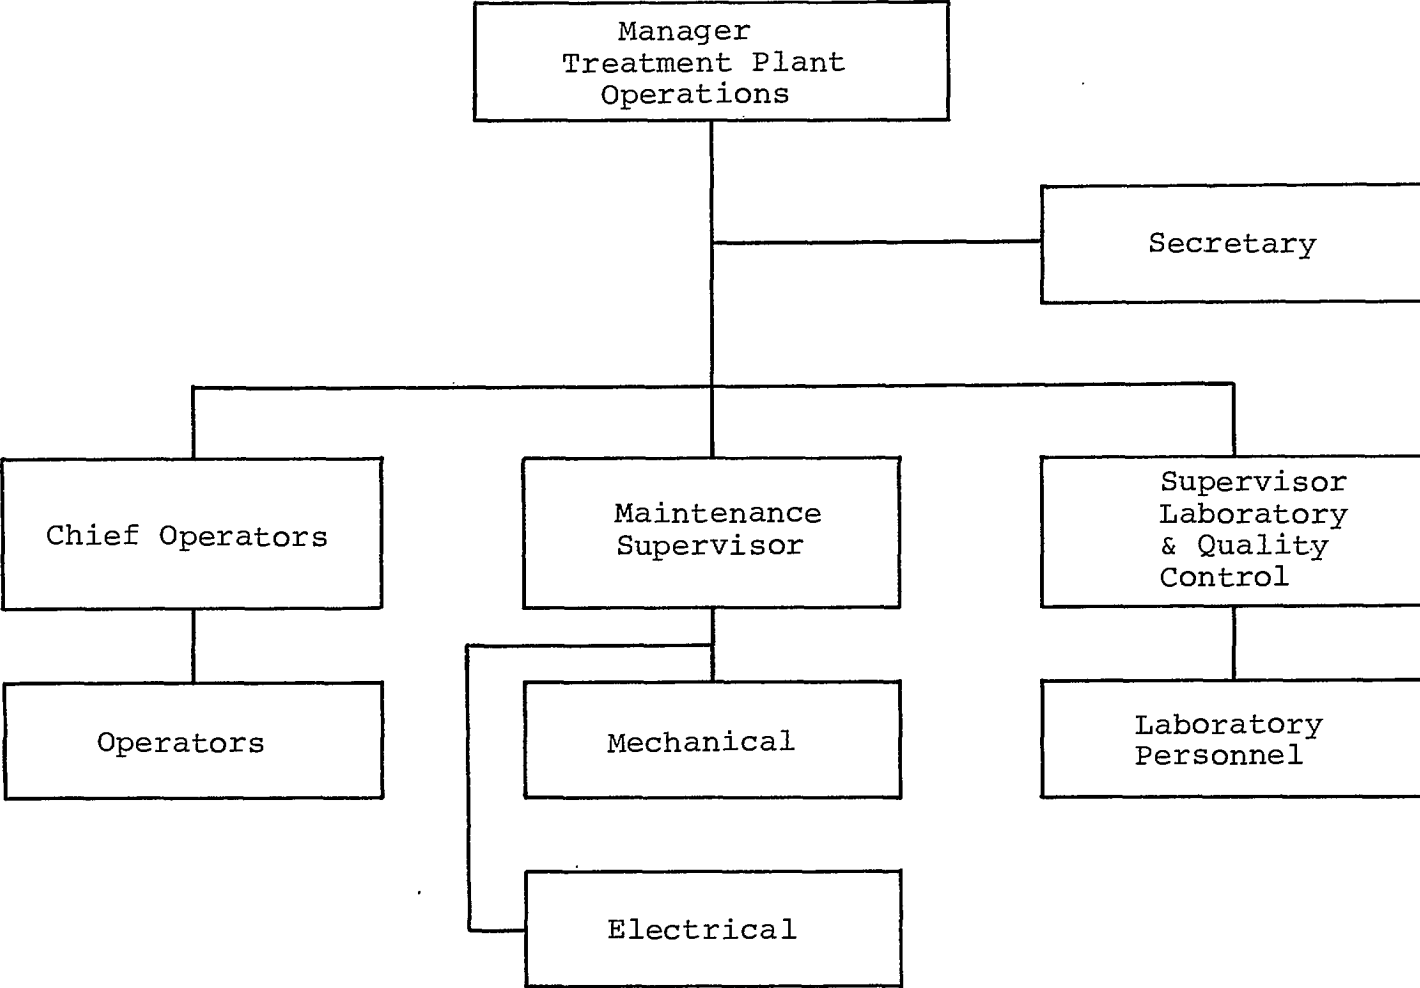

(ii) Treatment Plant Operations (Fig. 11.3)

This department will be concerned with the actual performances of mechanical operations of intake and treatment works that lead to the production of water.

Three basic sections will operate within this department - operations, maintenance, and quality control.

Operational staff will man the treatment plant(s) three shifts a day. A chief operator will head

FIGURE 11-3
DEPARTMENTAL ORGANIZATION

11.49

a team of plant operators per shift. The number of operators per shift may vary.

The maintenance crew, headed by a supervisor and comprising mechanical and electrical trades, will operate during the day shift. A skeleton team, say of one or two maintenance personnel, could man the treatment plant(s) during the afternoon and night shifts to cope with emergency situations.

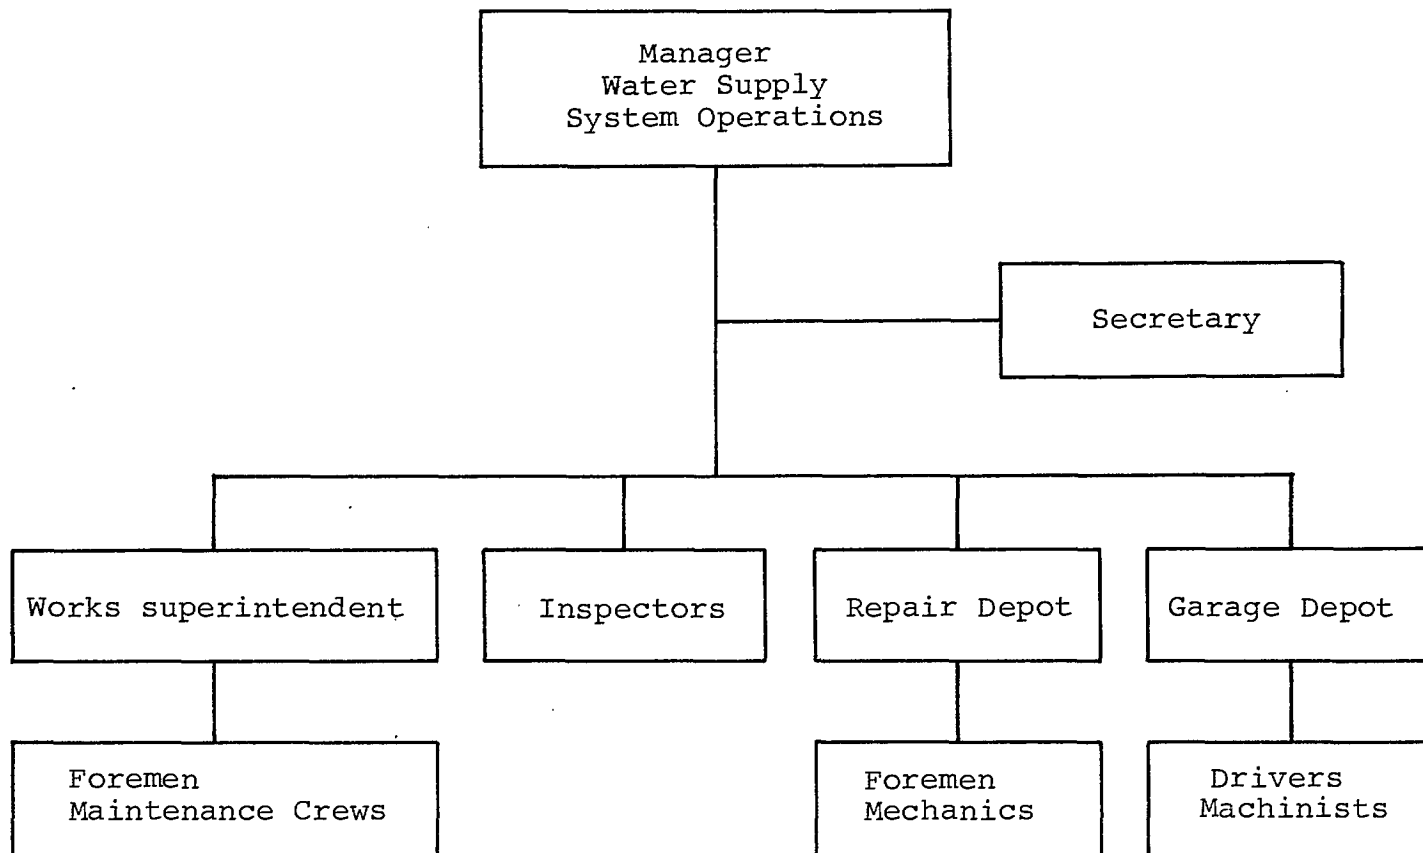

A laboratory will provide the analytical work required for the routine control of water quality. In addition, this laboratory could undertake special analytical programs such as those associated with sanitary survey of the watershed, and bench scale studies of treatment processes.

(iii) Water Supply System Operations (Fig. 11.4)

This department will be concerned with the actual performance of mechanical operations and maintenance of conveyance mains and pumping stations that lead to the supply of water to the communities within the region.

Works superintendents will be responsible for the maintenance in a good operating condition, and for repair of existing conveyance facilities, as well as the construction of new such facilities (by in-house forces). They could be organized territorially or according to tasks.

FIGURE 11-4
DEPARTMENTAL ORGANIZATION

11.51

FENCO

Each maintenance crew will be headed by a foreman, and will carry out the servicing, repair and construction when necessary, of all components of the supply system.

This department would also be responsible for maintaining and operating the repair depot and garage depot of the region.

(iv) Administrative Services (Fig. 11.5)

In addition to the conventional functions of office and personnel services, this department will be responsible for public relations, purchasing, and inventory control. We find it advantageous that the latter two functions be carried out separately, each being directly supervised by the department manager.

(v) Treasury (Fig. 11.6)

By nature of its functions, the treasurer's department should include three sections; that of the chief accountant, that of the budget director, and that of the supervisor of billing and collection.

The chief accountant's section will carry out basic accounting functions and maintenance of accounting records.

The budget director's section is basically entrusted with control functions over flow of monies handled by the chief accountant's section. As a separate section, the budget director

FIGURE 11-5
DEPARTMENTAL ORGANIZATION

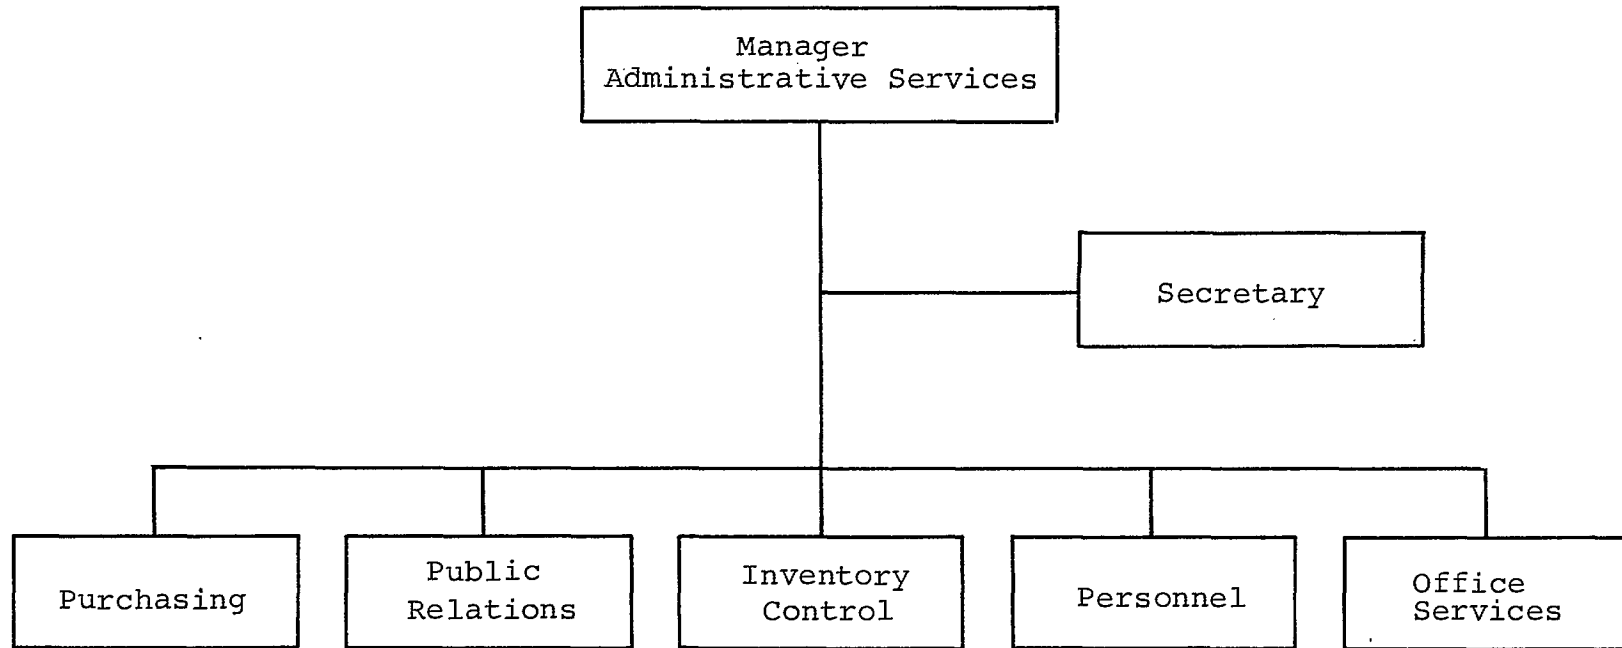

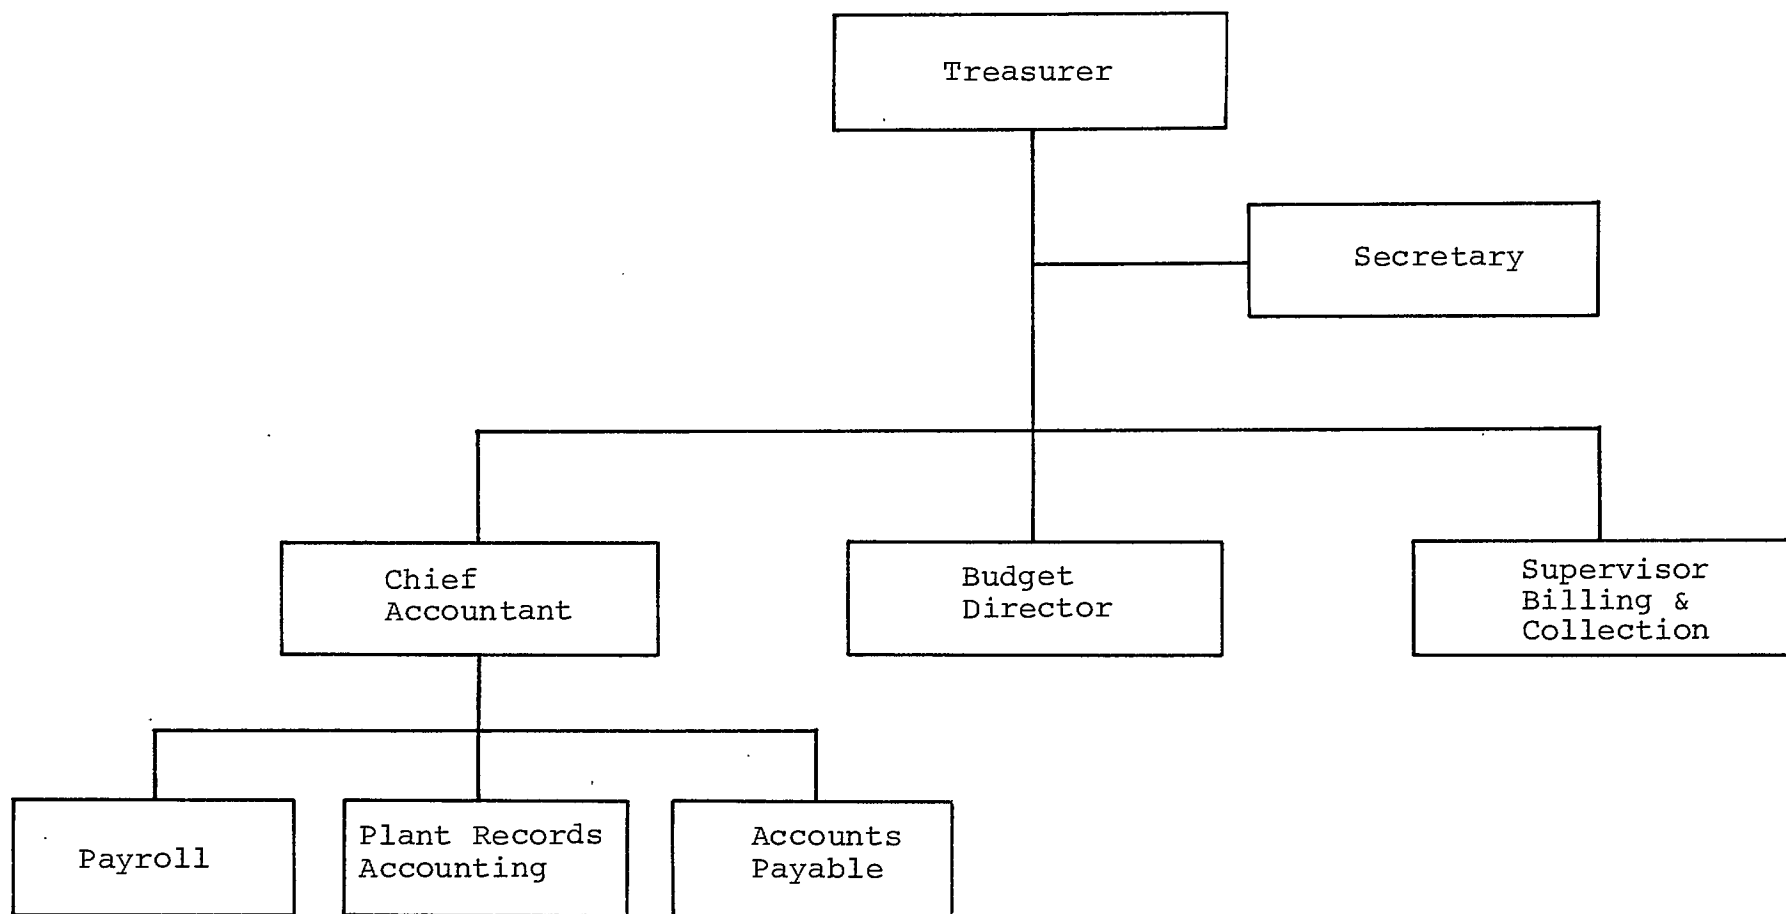

FIGURE 11·6
DEPARTMENTAL ORGANIZATION

11.54

FENCO

could deal more efficiently with other operational groups.

The volume and type of work involved in billing and collection justify direct control of these functions in a section responding directly to the treasurer.

IX. EVOLUTION OF THE MANAGEMENT ORGANIZATION

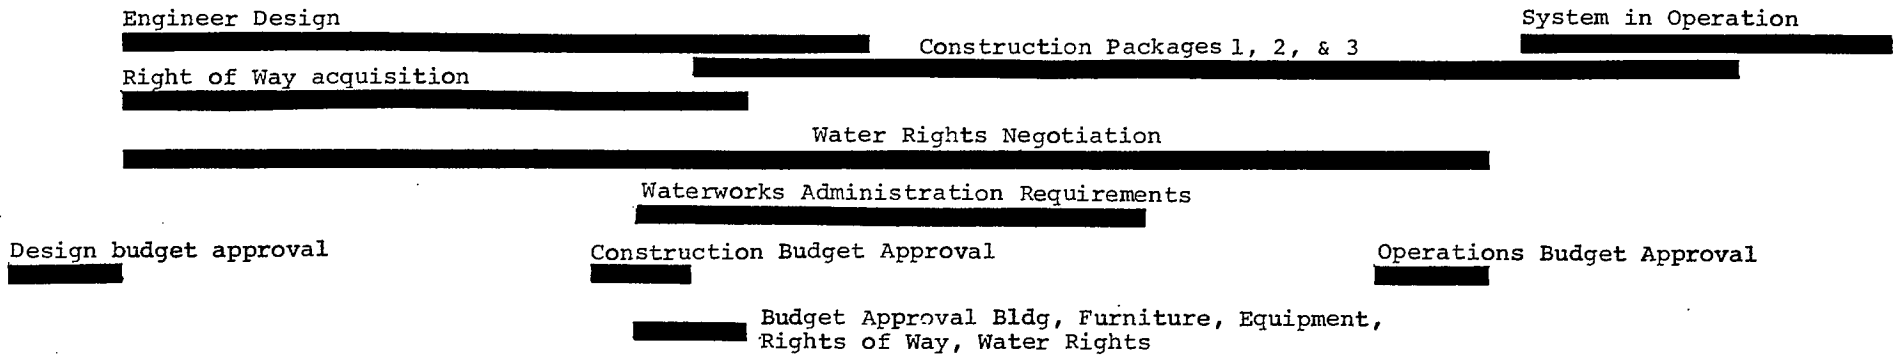

1. The Approach

As noted previously in this Chapter, the forecast water supply needs for the St. John's Regional Water System poses a need to proceed immediately with the design and construction of key components of the regional system (identified as packages No. 1, 2, and 3). The time element necessitated the formation of a "Steering Committee", comprising the provincial members of the study sub-committee, with authority to manage the engineering activities related to the design of the immediate development works (packages 1, 2, and 3). The end of 1975 has been tentatively adopted as the target date for putting in operation this first stage of the regional water supply system. The end of 1976 would appear to be a more realistic date. To meet this requirement we recommend that the task and organization schedules as shown in Figure 11.7 be adopted as the objectives of the "Steering Committee".

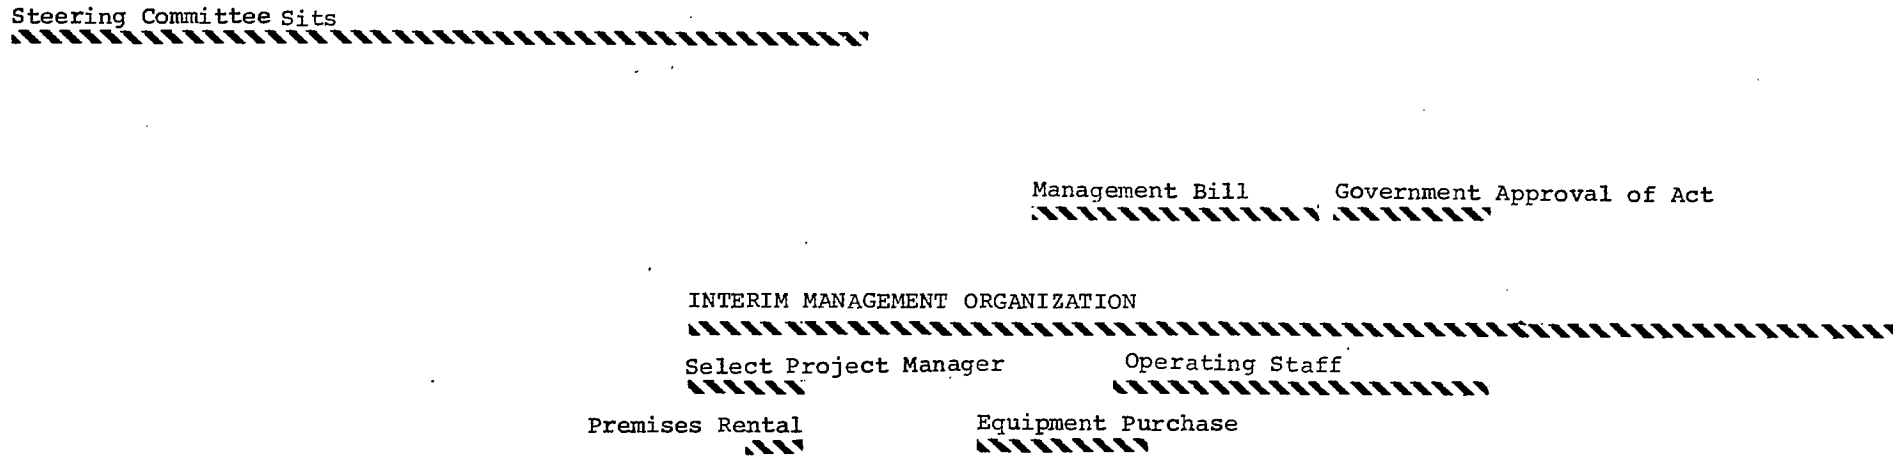

FIGURE 11 - 7 SCHEDULE FOR DEVELOPMENT OF ST. JOHN'S REGIONAL WATERWORKS SYSTEMS

1. WATERWORKS SYSTEM SCHEDULE PACKAGES 1, 2, & 3.

2. ORGANIZATION AND MANAGEMENT SCHEDULE

11.56

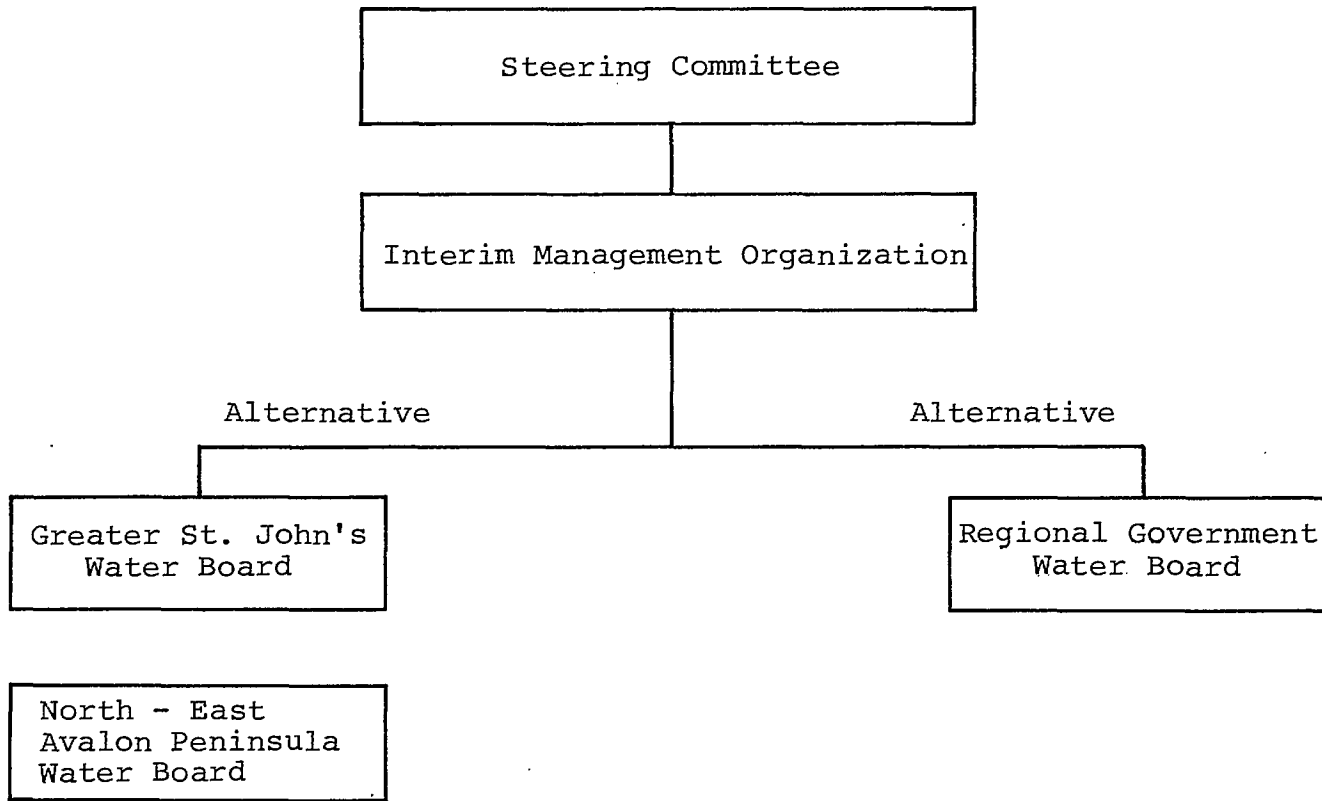

The "Steering Committee" will be replaced, in due course, by an "Interim Management Organization" as discussed in the first part of this Chapter, to be responsible for the construction of the first stage works and the establishing of "machinery" to settle administrative matters and the core of operating departments.

2. Evolution Stages

We envisage the management organization to evolve in the stages shown on Figure 11.8.

It can be seen that two courses of development are possible, one - parallel to the regional government, the other - to look after the water needs of the entire north-eastern section of the Avalon Peninsula, through regional and sub-regional systems. A decision to this effect would have to be made in due course based on the dictate of local socio-political conditions and requirements.
