

CAN/CGSB-3.24-2026

Supersedes CAN/CGSB-3.24-2023

Aviation turbine fuel

(Military grades F-34, F-37 and F-44)

Developed by the Canadian General Standards Board

Canadian General Standards Board statement

The CANADIAN GENERAL STANDARDS BOARD (CGSB), under whose auspices this standard has been developed, is a government directorate within Public Services and Procurement Canada. CGSB is engaged in the production of voluntary standards in a wide range of subject areas through the media of standards committees and the consensus process. The standards committees are composed of representatives of relevant interests including producers, consumers and other users, retailers, governments, educational institutions, technical, professional and trade societies, and research and testing organizations. Any given standard is developed on the consensus of views expressed by such representatives.

CGSB has been accredited by the Standards Council of Canada as a national Standards Development Organization. The standards that CGSB develops and offers as National Standards of Canada conform to the requirements and guidance established for this purpose by the Standards Council of Canada. In addition to standards it publishes as National Standards of Canada, CGSB may produce other deliverables that meet particular needs, in response to requests from a variety of sources in both the public and private sectors. CGSB standards and CGSB's National standards are developed in conformance with the policies described in the CGSB Policy and Procedures Manual for the Development and Maintenance of standards.

CGSB's standards are subject to review and revision to ensure that they keep abreast of technological progress. CGSB will review and publish this standard on a schedule not to exceed five years from the date of publication. Suggestions for their improvement, which are always welcome, should be brought to the notice of the standards committees concerned. Changes to standards may be issued as amendments or as new editions of standards.

An up-to-date listing of CGSB's standards, including details on latest issues and amendments, is found in the CGSB Catalogue at the following website, <https://www.canada.ca/en/public-services-procurement/services/standards-oversight/canadian-general-standards-board/development-services/catalogue.html>, along with more information about CGSB products and services.

Although the intended primary application of this standard is stated in its scope, it is important to note that it remains the responsibility of the users of the standard to judge its suitability for their particular purpose.

The testing and evaluations of a product or service against this standard may require the use of materials and/or equipment that could be hazardous. This standard does not purport to address all the safety aspects associated with its use. Anyone using this standard has the responsibility to consult the appropriate authorities and to establish appropriate health and safety practices in conjunction with any applicable regulatory requirements prior to its use. CGSB neither assumes nor accepts any responsibility for any injury or damage that may occur during or as the result of tests, wherever performed.

Attention is drawn to the possibility that some of the elements of this standard may be subject of patents right. CGSB shall not be held responsible for identifying any or all such patent rights. Users of this standard are expressly advised that determination of the validity of any such patent rights is entirely their own responsibility.

For enforcement purposes, standards shall be considered published the final day of the month of their publication date.

Standards Council of Canada statement

A National Standard of Canada is a standard developed by a Standards Council of Canada (SCC) accredited Standards Development Organization, in compliance with requirements and guidance set out by SCC. More information on National Standards of Canada can be found at <https://www.scc.ca>.

SCC is a Crown corporation within the portfolio of Innovation, Science and Economic Development (ISED) Canada. With the goal of enhancing Canada's economic competitiveness and social well-being, SCC leads and facilitates the development and use of national and international standards. SCC also coordinates Canadian participation in standards development, and identifies strategies to advance Canadian standardization efforts.

Accreditation services are provided by SCC to various customers, including product certifiers, testing laboratories, and standards development organisations. A list of SCC programs and accredited bodies is publicly available at <https://www.scc.ca/>.

Aviation turbine fuel

(Military grades F-34, F-37 and F-44)

This standard was developed by the **Canadian General Standards Board** and published in February 2026.

Translation of this National Standard of Canada was conducted by the Government of Canada.

Preface

This National Standard of Canada CAN/CGSB-3.24-2026 supersedes the 2023 edition.

Changes since the previous edition

- Addition of particle counting for assessing particulate contamination, including
 - Addition of Energy Institute methods IP 565 and IP 577, and ASTM D7619
 - Addition of Limiting values in 6.10.2
 - Changes to cleanliness statement in 10.7
- Changes to references of co-processed synthetic kerosene in sections 5.3 and 6.2
- Changes to tube deposit limiting values in 6.9.2 and removing table 2

The following definitions apply in understanding how to implement this National Standard of Canada:

- “shall” indicates a **requirement**;
- “should” indicates a **recommendation**;
- “may” is used to indicate that something is **permitted**;
- “can” is used to indicate that something is **possible**, for example, that an organization is able to do something.

Notes accompanying clauses do not include requirements or alternative requirements. The purpose of a note accompanying a clause is to separate explanatory or informative material from the text. Annexes are designated normative (mandatory) or informative (non-mandatory) to define their application.

Aviation turbine fuel (Military grades F-34, F-37 and F-44)

1 Scope

This National Standard of Canada applies to three grades of aviation turbine fuel (military grades F-34, F-37 as its equivalent, and F-44) consisting of conventional hydrocarbons, synthetic hydrocarbons, naturally occurring non-hydrocarbons and additives, as specified herein.

Grade F-34 is a kerosene-type aviation turbine fuel, and grade F-44 is a high-flash kerosene-type aviation turbine fuel. Kerosene-type aviation turbine fuels are distillates with a minimum flash point of 38 °C and high-flash type aviation turbine fuels are distillates with a minimum flash point of 60 °C. Grade F-37 is equivalent to grade F-34 with the addition of an approved thermal stability additive.

This standard describes three military grade fuels normally used in aviation and naval operations whose product quality parameters are influenced by international military standardization agreements. F-34, F-37 and F-44 are North Atlantic Treaty Organization (NATO) code numbers for products conforming to this standard.

Limitations for use – Aircraft operators should consult their aircraft manuals for the type of fuel, fuel additives or other limitations.

The testing and evaluation of a product against this standard may require the use of materials and/or equipment that could be hazardous. This document does not purport to address all the safety aspects associated with its use. Anyone using this standard has the responsibility to consult the appropriate authorities and to establish appropriate health and safety practices in conjunction with any applicable regulatory requirements prior to its use.

Units of measurement – Quantities and dimensions in this standard are provided in metric units from the International System of Units (SI units). This standard expresses the industry standard nominal units of measurement in North America of “% by mass” and “% by volume”. The SI equivalent expressions for these units are “% (m/m)” and “% (V/V)” respectively.

2 Normative references

The following normative documents contain provisions that, through reference in this text, constitute provisions of this National Standard of Canada. The referenced documents may be obtained from the sources noted below.

Note: The contact information provided below was valid at the date of publication of this standard.

An undated reference is to the latest edition or revision of the reference or document in question, unless otherwise specified by the authority applying this standard. A dated reference is to the specified revision or edition of the reference or document in question.

3 Terms and definitions

batch

an identifiable quantity of aviation turbine fuel with a single set of physical and chemical characteristics.

4 Classification

4.1 The aviation turbine fuel shall be classified in the following grades (see 9).

4.1.1 Grades

F-34;

F-37;

F-44.

5 General fuel requirements

5.1 Conventional hydrocarbons shall be predominantly petroleum-derived from natural gas-liquid condensates, crude oil and heavy oil, including bitumen from oil sands.

5.2 Synthetic hydrocarbons shall consist predominantly of hydrocarbons derived from non-conventional sources, such as biomass, natural gas, coal, fats, and oils by processes such as gasification, Fischer-Tropsch synthesis, hydroprocessing or hydrocracking.

5.2.1 Synthetic hydrocarbons are only permitted in military grade jet fuel in a blend with conventional hydrocarbons in accordance with ASTM D7566. Once the synthetic component has been confirmed to meet all requirements of the relevant Annex of ASTM D7566, it shall be blended with conventional blending components or jet fuel conforming to this standard. Once certified, any subsequent testing of the finished batch of fuel shall be done solely against the requirements of this standard.

5.3 Co-processing of non-conventional feedstocks as defined in the co-processing section of ASTM D1655, which at the time of publication of this standard is Annex A1, is recognized as being acceptable for production of co-processed synthetic kerosene as controlled by this standard.

The feed to co-processing units where jet fuel or jet fuel components are produced shall be limited in the portion of non-conventional feedstock, as defined in ASTM D1655. The final jet fuel product shall be limited to the maximum volumetric percentage specified in ASTM D1655 for the applicable non-conventional feedstock.

5.3.1 Co-processing of non-conventional feedstocks according to ASTM D1655 shall include the additional test requirements stated in the corresponding table of the Annex, as well as consideration of all text that is relevant to the specific feedstock being used. For example, Management of Change (MOC) processes and reporting of the amount of co-processed content are required.

5.3.2 Additional requirements apply for co-processed synthetic kerosene, according to ASTM D1655. Co-processed synthetic kerosene shall be tested against the requirements of Table 1 (6.4 to 6.13) of this standard and the additional requirements of ASTM D1655.

Once certified, any subsequent testing of the finished batch of fuel shall be done solely against the requirements of Table 1 (6.4 to 6.13) of this standard, and the additional requirements of ASTM D1655 no longer apply.

5.4 The fuel shall be visually clear and free from undissolved water and particulate matter at the point, time and temperature of custody transfer, commonly referred to as “Clear and Bright” or “Clean and Bright” (see 10.3).

If the initial sample fails, then resample and refer to 10.7 for additional guidance.

If there is a dispute regarding the presence of visible particulate matter, the dispute may be resolved by measurement of particulate matter according to ASTM D5452 being less than the limit specified in 6.10.2 (see 10.7). A sample that continues to be hazy is not acceptable.

5.5 The odour of the fuel should not be nauseating or irritating.

6 Detailed requirements

6.1 The detailed requirements shall apply to the fuel unless otherwise specified.

6.2 The fuel shall comply with the detailed requirements specified in 6.4 to 6.13, using the test methods indicated. The specified limiting values shall not be changed. This precludes any allowances for the test method precision and adding or subtracting digits.

6.2.1 Each batch of fuel that includes synthetic hydrocarbons defined in 5.2 shall also comply with the extended requirements specified in ASTM D7566 Table 1, Part 2 at point of batch origination.

6.2.2 Each batch of fuel that includes co-processed synthetic kerosene defined in 5.3 shall also comply with the extended requirements in ASTM D1655 at point of batch origination.

6.3 To determine conformance with the specific limiting values, an observed value or a calculated value shall be rounded off “to the nearest unit” in the last right-hand digit used in expressing the specified limiting values, in accordance with the rounding-off method of ASTM E29. Zeroes trailing the last nonzero digit for numbers represented with a decimal point are significant digits, in accordance with ASTM E29. There are two exceptions (see 6.5.1 and 6.5.4 depending on the method used) that shall be reported to the nearest 0.5 °C.

6.3.1 Where test values differ between two parties, a resolution shall be in accordance with ASTM D3244 in order to determine conformance with the specified limiting values, with the criticality of the limits set as $P = 0.5$.

6.13.6	Leak detection additive (see 7.7), mg/kg, Optional	—	1	—	1	—
^a In the event of a dispute, this method shall be the referee method. ^b Ensure the validity of dye when using this method. ^c The mercaptan sulphur determination may be waived if the fuel is considered “sweet”, and received a negative result by the doctor test described in ASTM D4952. ^d When testing in accordance with ASTM D2887, apply the relevant Annex to convert distillation temperature results to estimates of ASTM D86 results. ^e Only bias-corrected values from ASTM D7345 shall be used as an alternate to ASTM D86. ^f If ASTM D2887 is used to determine distillation temperature (see 6.5.1), then residue and loss requirements shall not apply because no residue or loss results from the application of ASTM D2887. ^g The results obtained by ASTM D3828 can be up to 2 °C lower than those obtained by ASTM D56, which is the referee method.						

Property	Specified limiting values				
	F-34 and F-37		F-44		Test method
	Min.	Max.	Min.	Max.	ASTM
^h	CAUTION: Results from two extensive round-robin tests reported in ASTM Research Reports 1536 and 1572 demonstrated that the manual freezing point test ASTM D2386 could only detect heavy material contamination (e.g. diesel fuel) in JET A-1 fuel (equivalent to F-34 and F-44 fuels) in less than half of the cases tested, whereas the automatic freezing point test ASTM D5972 was effective at detecting such contamination in all cases tested.				
ⁱ	The SI unit for kinematic viscosity is the square metre per second. The preferred multiple for fluids in this viscosity range is the square millimetre per second, which is equivalent to a centiStokes (i.e., 1 mm ² /s = 1 cSt).				
^j	Only bias-corrected values from ASTM D7042 shall be used as an alternate to ASTM D445.				
^k	Calculate and report the net heat of combustion corrected for the sulphur content when using these empirical test methods. At the time of publication of this standard, the measurement of sulphur via ASTM D7039 is not permitted for the calculation of Net Heat of Combustion according to ASTM D3338.				
^l	Thermal stability shall be determined using the thermal oxidation stability test instrument at a minimum heater-tube-controlled temperature of 260 °C. The SI unit equivalent for the pressure differential is 3.3 kPa. However, the thermal oxidation stability test instrument gives the results in mm Hg, and 25 mm Hg is the exact maximum.				
^m	If there is a dispute regarding the presence of visible particulate matter, the dispute may be resolved by measurement of particulate matter according to ASTM D5452 being less than the limit specified in 6.10.2 a) (see 10.7). A sample that continues to be hazy is not acceptable.				
ⁿ	In the event of a dispute between 6.10.2 a) particulate matter and 6.10.2 b) particle count, 6.10.2 a) particulate matter shall be the referee test method.				
^o	If particle count limits are exceeded, a chemical pre-treatment in accordance with the applicable appendix or annex of ASTM D7619, IP 565, or IP 577 may be applied to eliminate free water, and cleanliness re-determined. In such cases, results before and after the chemical pre-treatment shall be reported.				
^p	MSEP by ASTM D7224 and WSI by D8073 can both be useful in determining the water separation characteristics of a batch of jet fuel even when additized with a static dissipator additive and certain other additives that do not actually degrade water separation performance in coalescing separators. When a corrosion inhibitor/lubricity improver (see 7.6) is added, the water separation characteristic limits apply before its addition. For clarity water separation characteristic results shall be reported by test method (i.e., MSEP by ASTM D3948 or MSEP by ASTM D7224 or WSI by ASTM D8073). Test results failing to meet the stated specification limits for MSEP / WSI downstream of the point of manufacture may not be used as the sole reason for rejection of a batch of fuel and are cause for further investigation (see 6.3.1).				
^q	Conductivity often drops during fuel distribution due to additive depletion and lower temperatures, so it is common practice to initially additize at the upper end of the conductivity range.				
^r	Hydrogen-processing is any petroleum refining process that uses hydrogen in the presence of a catalyst.				

6.14 Sulphur

The accuracy of ASTM D7039 for the sulphur content of jet fuel beyond 2822 mg/kg has not been validated. Users are cautioned to conduct their own validation when using this test method for jet fuel containing more than 2822 mg/kg sulphur.

7 Additive requirements

7.1 Only the additives listed in 7.2 to 7.8 may be added to the fuel. Refer to 6.13 for specified limiting values and test methods for each property. The supplier shall record the amount and names of each additive added to the fuel.

7.1.1 The amount of each additive used in the fuel shall be determined by the test method (see 6.13 and 10.5) or by volume reconciliation. Procedures for volume reconciliation should include recording the volume of additive introduced to the fuel and the volume of fuel additized in appropriate units.

7.2 Static dissipator additive

7.2.1 Static dissipator additive (SDA) AvGuard™ SDA¹ or STADIS® 450² shall be added to the fuel when necessary to meet the electrical conductivity requirements specified in 6.12.1. The original concentration of the SDA shall not exceed 3 mg/L.

7.2.2 When additive depletion is evident by conductivity loss, further addition of the SDA is permitted as follows:

- a) if the original concentration of the SDA is not known, then an original addition of 3 mg/L is assumed and further addition of SDA shall not exceed 2 mg/L;
- b) the cumulative concentration of the SDA shall not exceed 5 mg/L.

7.2.3 Electrical conductivity varies with temperature. A typical relationship follows:

$$\log k_t = a(t - t_1) + \log k_{t_1}$$

where:

k_t = electrical conductivity at temperature t , °C;

k_{t_1} = electrical conductivity at temperature t_1 , °C;

a = a temperature-conductivity factor that depends on fuel composition but normally is within the range 0.013 to 0.018 for kerosene-type aviation turbine fuels.

7.2.3.1 The temperature-conductivity factor, a , increases at or below an approximate temperature of -10 °C. For conductivity at very low temperatures, it is recommended that a separate factor be determined based on actual measurements at the lowest temperatures that are assumed will be encountered. For more information on how low temperature affects conductivity, see the relevant Appendix of ASTM D2624.

¹ AvGuard™ SDA, a registered trademark of Afton Chemical Corporation, 500 Spring Street, Richmond, VA 23219, is manufactured in the United States and distributed globally by Afton Chemical Corporation.

² STADIS® 450, a registered trademark of Innospec Fuel Specialties LLC, is manufactured in the United States and distributed globally by Innospec Fuel Specialties LLC.

7.3 Antioxidant additives

7.3.1 The addition of antioxidants is mandatory for the hydrogen-processed portion of the fuel, but optional for the non-hydrogen-processed portion of the fuel (see 6.13.2).

7.3.2 Only the following antioxidants may be added separately or in combination with the fuel. The total concentration (not including mass of solvent) shall not exceed 24 mg/L:

- a) 2,6-di-*tert*-butylphenol;
- b) 2,6-di-*tert*-butyl-4-methylphenol;
- c) 2-*tert*-butyl-4,6-dimethylphenol (2,4-dimethyl-6-tertiary butylphenol);
- d) 75% minimum, 2,6-di-*tert*-butylphenol,
25% maximum mixture of *tert*- and tri-*tert*-butylphenols;
- e) 55% minimum, 2-*tert*-butyl-4, 6-dimethylphenol (2,4-dimethyl-6-tertiary butylphenol),
15% minimum, 2,6-di-*tert*-butyl-4-methylphenol.
Remainder as methyl and dimethyl *tert*-butylphenols;
- f) 72% minimum 2-*tert*-butyl-4,6-dimethylphenol (2,4-dimethyl-6-tertiary butylphenol),
28% maximum, methyl and dimethyl *tert*-butylphenols.

Note: The names of the antioxidants conform to the International Union of Pure and Applied Chemistry (IUPAC) naming convention. In some cases, the common name of the antioxidant has been included in brackets after the IUPAC name.

7.4 Metal deactivator additive

Only *N,N'*-disalicylidene-1,2-propane-diamine may be added as a metal deactivator at a concentration not exceeding 2.0 mg/L (not including mass of solvent) on the initial fuel manufactured at the refinery. Higher concentrations are permitted in circumstances where copper contamination is suspected to occur during distribution. Cumulative concentration of metal deactivator when re-treating the fuel shall not exceed 5.7 mg/L (see 10.2).

7.5 Fuel system icing inhibitor

A fuel system icing inhibitor conforming to ASTM D4171 (Type III [DIEGME]) shall be added to the fuel within the limits specified in 6.13.4.

7.6 Corrosion inhibitors/lubricity improvers

A corrosion inhibitor/lubricity improver qualified to U.S. Military Specification MIL-PRF-25017 and listed in the associated qualified product list (QPL) 25017 shall be added to the fuel (see 10.1). The concentration of the additive in the fuel shall be as specified in the QPL, and its introduction into the fuel shall be separate from the addition of other additives.

7.7 Leak detection additive³

Only Tracer A (LDTA-A®)⁴ may be added as a leak detection additive. The maximum concentration is 1 mg/kg.

7.8 Thermal stability additive

Only the following thermal stability additives may be blended with F-34 at the following concentrations to make F-37 fuel grade: SPEC AID 8Q462W™⁵ at 256 mg/L of fuel.

8 Inspection

A sample of the size specified by the testing authority shall be obtained in accordance with ASTM D4057. For automatic sampling, ASTM D4177 shall be used. Sample volume should be consistent with the requirement of the testing laboratory, the authority having jurisdiction or both.

9 Option

The following option shall be specified in the application of this standard: grade F-34, grade F-37 or grade F-44 (see 4.1).

10 Precautions

10.1 Lubricity information statement

10.1.1 Lubricity, which is the ability of jet fuel to act as a lubricant for certain aircraft fuel-wetted components, can vary considerably. It depends on the design, materials used and the intrinsic lubricity of the fuel. There have been a number of cases of engine hardware failures directly attributed to poor-lubricity fuel.

10.1.2 ASTM D5001 may be used to determine the lubricity quality of the fuel. Hydrogen-processing⁶ usually produces fuels with poor lubricity. Blending or commingling with non-hydrogen-processed fuels will improve lubricity, and the use of corrosion inhibitor/lubricity-improver additives may offer a solution (see 7.6).

10.1.3 Problems are more likely to occur when aircraft operations are confined to a single refinery source where fuel is severely hydrogen-processed and where there is no commingling with fuels from other sources during distribution between refinery and the aircraft.

10.2 Copper information statement

10.2.1 The contamination of jet fuel can occur during manufacture or during distribution in marine vessels with copper coils, and from the copper-alloy components and fittings in sampling points.

³ The Tracer Tight® methodology to detect and locate leaks in ground-based fuel storage, delivery and dispensing systems does not form part of this standard. Refer to the additive supplier for this information. Linde plc can be contacted at 10 Riverview Drive, Danbury, CT 06810; telephone 1-844-445-4633; Web site: www.lindeus.com.

⁴ Tracer A (LDTA-A®) is a registered trademark of Linde plc.

⁵ SPEC AID 8Q462W is a registered trademark of GE Power & Water Process Technologies.

⁶ Hydrogen-processing (also called hydroprocessing) is any petroleum refining process that uses hydrogen in the presence of a catalyst.

10.2.2 Trace levels of copper, in the parts per billion range, can be sufficient to degrade the ASTM D3241 thermal oxidation stability test instrument test result. Where the possibility of copper pickup is suspected, an approved metal deactivator, as specified in 7.4, may be added to preserve or restore the thermal stability of the fuel, or both.

Note: ASTM D6732 can be used to measure the level of copper in jet fuel.

10.3 Colour information statement

While this standard does not have a colour requirement, colour may be a useful indicator of fuel quality or contamination. Normally, fuel colour ranges from water white (colourless) to a pale straw yellow. Other fuel colours can be the result of crude oil characteristics or refining processes. Darkening of fuel or a change in fuel colour can be the result of product contamination and can indicate that the fuel is off specification, which could render it unfit and not acceptable for aircraft or engine use, or both. Fuel having various shades of colour, that is, pink, red, green, blue, or a change in colour from the supply source should be investigated to determine the cause of the colour change to ensure suitability for aircraft or engine use, or both.

10.4 Water separation characteristic information statement

The ease of coalescence of water from fuels as influenced by surface-active agents (surfactants) may be assessed by ASTM D7224, D3948 or D8073. A high water separation characteristic rating suggests a fuel free of surfactants, whereas a low rating indicates the presence of surfactants. Surfactants can disarm coalescers, thus allowing water to pass through coalescer filters and remain in the fuel. Surfactants can be introduced into the fuel downstream from a refinery distribution system, in storage facilities or deliberately introduced through the addition of specific approved additives. In light of the factors that can degrade water separation characteristics, options such as supplying higher water separation characteristics than the minimum specification should be considered at the point of origin depending upon the means of distribution.

Due to the impact water can have on storage facilities and aircraft, and the resources associated with correcting off-specification fuel, it is recommended that test methods with the best precision, reflecting current filter media and ease of operator use, be adopted.

10.5 Refinery processing additive information statement

Additives used in refinery processes, such as corrosion inhibitors, can be carried over in trace quantities into aviation fuel. In a few isolated cases, this has resulted in operational problems in aircraft fuel systems. Moreover, the tests and requirements specified in this standard may not be sufficient for detecting trace levels of refinery processing additives. It is therefore recommended that adequate quality assurance and management of change procedures, such as formal risk assessments, be in place to ensure that any relevant refinery processing additive use is well defined and controlled in order to maintain the quality of the finished product.

10.6 Contaminants – Incidental materials – Biodiesel information statement

Biodiesel (fatty acid methyl esters or FAME) is not an approved component in aviation turbine fuels. The use of FAME in other fuels has raised concerns about contamination of aviation turbine fuels, particularly in non-dedicated distribution systems such as multi-product pipelines, marine vessels, railcars and tanker trucks.

The amount of incidental FAME (as defined by ASTM D6751, CAN/CGSB-3.524 or EN 14214) shall not exceed 50 mg/kg. Producers, distributors and users need to take appropriate precautions to avoid contamination. The supplier shall establish the need to test for FAME based on various risk factors that can lead to FAME contamination. Suitable test methods for determining the concentration of FAME in aviation turbine fuels are ASTM D7797, IP 583, IP 585, IP 590 and IP 599. IP 585 shall be the referee method in case of dispute.

10.7 Cleanliness information statement

Fuel cleanliness changes during the storage and distribution of fuel. Cleanliness is achieved by the use of various filtration systems and by allowing the fuel to settle over time in storage. This facilitates the removal of both particulate matter and undissolved water. The visual appearance of fuel is an indicator of contamination by particulate matter and undissolved water. However, interpretation of this requirement is subjective. Procedures such as ASTM D4176 Procedure 1 and CAN/CGSB-3.0 No. 28.8 can be used to rapidly evaluate fuel cleanliness. Note that it is essential that representative fuel samples are obtained. During and after receipt of a shipment of aviation fuel, assessment of cleanliness (e.g., by particle counting or visual inspection) can be accomplished by taking several appropriate samples. Quantitative limits for particulate matter and particle count are given in paragraph 6.10.2.

10.8 Storage and distribution information statement

This standard applies to fuel as it is supplied to an aircraft. However, it is normally applied at the point of manufacture and at points of custody transfer. Some of the specified properties can change during storage and distribution so appropriate quality assurance testing and handling procedures should be followed. Standards, recommended practices and other guidelines for appropriate testing and handling procedures are available from the Energy Institute (EI), the American Petroleum Institute (API), the Joint Inspection Group (JIG), the International Air Transport Association (IATA), the International Civil Aviation Organization (ICAO), Airlines for America (A4A) and the CSA Group (CSA). Changes in how fuel is handled during storage and distribution should be subject to a Management of Change (MOC) study.

ASTM E29 – Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

Annex B
(informative)

Significance of viscosity requirements for aviation fuels

B.1 Some engine and auxiliary power unit (APU) manufacturers specify a maximum viscosity of 12 mm²/s to ensure satisfactory low temperature operation. Aviation turbine fuel viscosity can exceed 12 mm²/s as the fuel temperature approaches the specification freeze point maximum when the viscosity at -20 °C exceeds 5.5 mm²/s for Jet A (-40 °C freeze point) or 4.5 mm²/s for Jet A-1 (-47 °C freeze point).

B.2 The atomization characteristics of fuel nozzles used in propulsion engines and APUs is such that successful cold engine starts may not be achieved at fuel viscosities above 12 mm²/s (12 cSt). This can potentially impact certain aircraft operation such as limiting the low temperature start envelope, which could impact extended twin operations. While there are no known field problems at this time, there needs to be further discussion on the need for all the fuel being delivered to these engines to have a 12 mm²/s (12 cSt) maximum viscosity and on how this could be accomplished (for example, through fuel specification changes, airframe or APU design changes, or operational changes).
